There is a varying degree of anaemia. Its amount depends on the result of the rival forces of blood destruction and construction. The gravity of the anaemia is not measured only by the number of red cells, but by the amount of marrow effort required to maintain that red cell count. The anaemia is of the secondary type unless it becomes severe and the patient ill, when there may be close assimilation to the blood picture of pernicious anaemia. A habitual low red cell count is in this disease, as in others, compatible with absence of symptoms. Is this some unknown process of adaptation? In the present list of cases there are records of several patients playing their parts in the world with 3½ to 3 million red cells, and a colour index well under 1.

Microcytosis is a feature, so much so that a number of small red cells of dark colour seen in a film will suggest the disease. Reticulocytes are more numerous than in any other condition; their presence is evidence of activity in red cell formation. From 5 to 15 per cent. is a reading commonly recorded, but when a big effort is being called forth the reticulocytes may reach to 30, 40, or even 60 per cent.; in no other disease are such high readings found.

Fragility

The fragility of the red cells, in contrast to pernicious anaemia, where the red cells have an increased resistance, is commonly greater than that of normal blood. The method devised by Creed[32] for measuring the fragility is especially reliable. The point at which haemolysis commences shows some variation, but the point at which it is complete shows consistency, among the records of different observers. Fragility of the blood of haemolytic icterus varies not only in different subjects, but in the same subject. Taking the average fragility of normal blood as 0.45 to 0.35, the range in haemolytic icterus may be as high as 0.8. Its extent is not an indication of the severity of the clinical condition, and though increased fragility is a usual finding, it is not a necessary feature of the disease. Thus five cases of those specially under review had normal fragility, and Gänsslen[31] reports that in 10 per cent. of cases of acholuric jaundice there is no increase of fragility. In short, increased fragility is a factor not an essential feature—an adaptable part of a larger mechanism. Of the cases treated by splenectomy, in some the fragility is diminished after the operation without reaching the normal. Thus in this series

0.75 was 0.5 when examined three years later.
0.65 was 0.5 immediately, and four years after operation.
0.8 was 0.5 three years later.
0.7 was 0.55 twelve years later.
0.75 was 0.62 soon after.

In at least as many cases the fragility was unchanged, and Creed[33] had one case in which the fragility increased after splenectomy. The fragility is thus a variable feature, and there is no certain parallelism between its measure of increase and the severity of the jaundice, or the anaemia, or the splenomegaly. All these factors make varying contributions to the genesis of the condition. An interesting association between microcytosis and increased fragility is brought out by the observation that in various mammals those with the smaller red cells have the higher fragility (Krumbhaar).[34] Vallery-Radot and L'Heritier[35]

CASES, WITH COMMENTARY

I will now consider some cases in detail and, through them, certain aspects and relationships of this disease. Let us first study the family, "Tope," under the care of Dr. Sydney Atkin.

The mother began to show jaundice at the age of 6; she is now 44; she has borne four children, and leads an active life. She is always somewhat jaundiced. There is no family history of jaundice and no evidence of increased fragility in several members of the family who have been investigated. The spleen extends to the iliac crest and to the middle line; liver just palpable. The data may be set forth in tabular form (Table I).

This patient runs a busy home without apparent effort and with an average of about 3¼ million red cells—a fact which prompts the reflection that mere "numbering of the people" is an imperfect criterion of functional efficiency. A study of her chart (Table I) shows her haemolysis to be considerable, and her bone marrow is having a struggle to keep pace. The red cell count may decline further without making sign until a dangerous haemolytic anaemia appears. Moreover, the capacity of her bone marrow is more likely than not to decrease with the passing of the years. Splenectomy would be the wise course.

"P. Tope," aged 12, daughter of the foregoing, a well-made child with healthy heart and lungs. She began, at the age of 2, to have attacks of vomiting lasting about two days. She has always been pale rather than yellow, and the yellowness has never been more than a tinge. When 8 years old she had an acute illness, which was characterized first by vomiting and then by progressive pallor and weakness, the spleen being noted as large and firm, and reaching to the iliac crest; the heart became dilated, and a systolic murmur was audible over the precordium. Recovery took place after a fortnight, and about three weeks later the skin and conjunctivae were definitely, though slightly, icteric, and there was marked pallor; the spleen filled the left side of the abdomen; the liver was not felt; glands were not enlarged. The initial blood and other findings are dated August 12th, 1927, in the subjoined table.

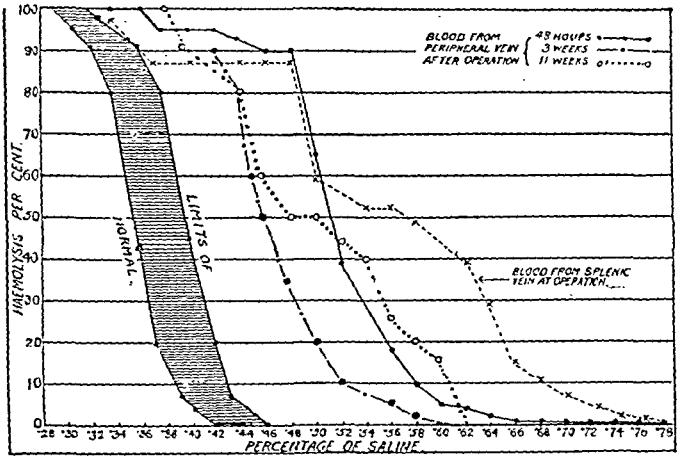

FIG. 3.—"P. Tope." Fragility of red cells.

The fragility of the blood is even better appreciated from the chart (Fig. 3). The vertical column of figures on the left stands for percentages of haemolysis; the horizontal figures indicate percentages of saline.

In February of the following year the red cell count had improved, but the reticulocytes had increased to 11 per cent., and there was marked microcytosis—a feature characteristic of this condition. Further, the van den Bergh test was as high as 5.5. There was thus a good deal of blood destruction with an active blood formation. Mere counting of red cells would have given a false impression of security. The next event was the performance of splenectomy by Mr. T. P. Dunhill, and at the same time a sample of bone marrow from the upper end of the tibia was taken. The recovery both of the patient and of the patient's blood has been notable (Fig. 4), and Table II sets it forth in graphic manner. Note the dates along the base, and the vertical column full of figures. Note the four curves, showing the red cell counts, the reticulocyte counts, which are good evidence of active formation of blood in the marrow; note the plasma-bilirubin and cholesterol. Note the 6 million red cells on March 19th, and the high red cell readings on subsequent dates; at the same time the reticulocytes and the plasma-bilirubin fell within normal limits. This polycythaemia means that splenectomy has done more than we wanted; there was no physiological necessity to remove the whole spleen.

Beer[36] draws attention to the polycythaemia that may result from splenectomy, stating that as high as 13,000,000 red cells have been recorded. Weinert[37] is an advocate of more conservative surgery, such as ligation of the splenic vessels, and he recalls that the first historical record in the surgery of the spleen was the ligature of the splenic vessels by Viard in the sixteenth century. It must be remembered, however, that ligation of the splenic vessels can be more difficult than the removal of the whole spleen, and its effects more difficult to control. There is at that point not enough haemolysis, an accumulation of old red cells, and no call for new ones. (So reticulocytes are very few.) This happening resembles that found in animal experiments. The low reading of cholesterol in the blood and its sharp rise after splenectomy is significant; the same will be noted with the case of E. H. below. In contrast, however, other cases show an approximately normal blood cholesterol content. The spleen weighed 12 ounces, showed great congestion, and a little iron-free pigment. A notable feature of this case was the sudden and dangerous illness due to acute haemolysis.

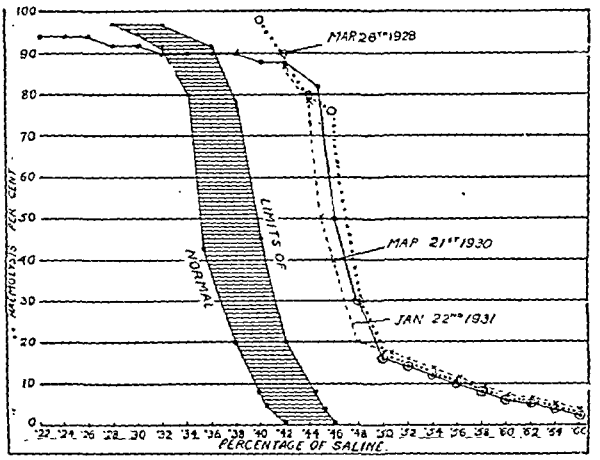

FIG. 5.—"B. Tope." Fragility of red cells.

"S. Tope."—An attack of acute illness with splenomegaly similar to that which nearly killed "P. Tope" was fatal to this younger sister, aged 3½, in the year 1927. This child's health had previously been excellent, and she had never shown any icterus. Her illness began acutely with vomiting; the spleen was palpable; pallor and weakness rapidly increased, and death occurred in six days. Blood tests are lacking here, but the close resemblance between the illnesses of the two sisters is highly suggestive. The presence of jaundice in the sister and its absence here is in keeping with known facts. The liability to severe haemolytic crises with short or no warning in this disease should be borne in mind. In this series of cases seven patients showed this feature, and of these three succumbed.

"B. Tope," aged 10, another daughter, has never been jaundiced or ill. Though pale, she has always been active and vivacious. In 1928 her spleen reached to the umbilicus. The report on the findings then and subsequently arising forth in Table III. (The graph of the fi... of red cells is shown in Fig. 5.)

Can there be any doubt that th... child, however well she appears, should have her spleen removed?

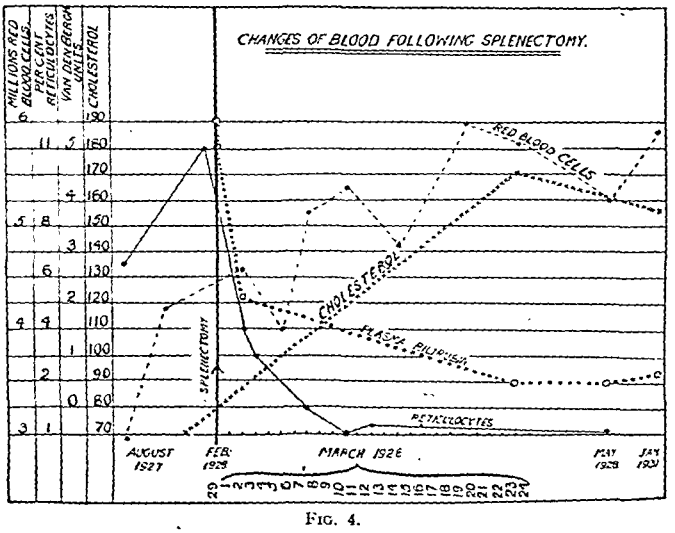

FIG. 4.

										0.6–0.3	

This family shows notable variety in the features of the disease; the mother definitely icteric and anaemic, yet working hard and without apparent difficulty; "P. Tope," more anaemic than jaundiced, nearly killed by an acute attack of haemolytic anaemia, and cured by splenectomy. The younger sister ("S. Tope") died from an acute attack of haemolytic anaemia, and had little or no jaundice. "B. Tope" is active and vivacious, has never yet been ill or jaundiced, yet is anaemic, and has the same high fragility of 0.6 and a raised indirect van den Bergh reaction.

The following two cases—I. S., aged 11½, and H. S., aged 10—illustrate the attacks of anaemia referred to above, though in milder form. These were characterized by restlessness and sleeplessness, and increasing pallor and weakness, and had a greater proneness to occur in cold weather. Both boys has an icteric tinge and enlarged spleens.

Van den Bergh reaction in I. S., 5 units—positive indirect; in H. S., 2.5 units—positive indirect. Blood: I. S., 4,500,000 red cells, colour index 0.84, haemoglobin 78 per cent.; H. S., 4,780,000 red cells, colour index 0.9, haemoglobin 85 per cent. Fragility in each case within the normal.

E. H., a girl aged 15, exemplified Chauffard's description, "*plus ictériques que malades.*" But for jaundice, which had been with her since babyhood, this girl had the appearance of health and vigour. Yet a study of her case shows how unstable was her present, how perilous her future. The spleen was palpable.

A study of this table (IV) suggests the following reflections. In spite of appearances the anaemia was pronounced, the haemolysis as shown by the van den Bergh reaction considerable, and the innate reserve power of this patient's bone marrow none too good, for the output of reticulocytes (a maximum of 14 per cent.) before the operation was not striking in face of the need; and a constant high colour index with that red cell count is not a good sign. Moreover, when the strain of haemolysis was slow. With such a recovery of the red cell count was slow. With such a haemolysis might have come like "a patient a severe haemolysis might have come like "a thief in the night." Such a haemolysis nearly killed "P. Tope," and did kill her younger sister. Following the splenectomy, the plasma-bilirubin fell to normal in four days, and there was a change in the patient's complexion. The reticulocyte count reached normality in ten days, but, as just stated, the red cells have been slow in recovery, since, four months after the operation, they were only 4,400,000. Contrast this with "P. Tope": a week after her splenectomy her red cells were over 5 millions, and in three weeks 6 millions, either because her pre-operation haemolysis was less or because her bone marrow gave more response when the destructive force was removed. The point worthy of comment is that the low cholesterol content of the blood present in the

TABLE IV.—E. H.

"Tope" family, and which rose strikingly after the removal of "P. Tope's" spleen, did not exist in this case. E. H.'s gall-bladder was thickened, and contained pigment-calcium calculi, together with a cluster of white calcium carbonate crystals. No organism could be grown from the centre of a calculus—that is, the calculi were of metabolic, not of infective, origin.

THE FAMILIAL FEATURE

The following case is cited as illustrating the familial feature.

W. G., male, was first seen on August 17th, 1924, aged 34, with the following history. He was quite well up to the age of 22, when pain in the left upper abdomen led to the discovery that he had a spleen enlarged to the umbilicus; he was anaemic, and had a slight yellow tinge. A diagnosis of splenic anaemia was made, and splenectomy advised but refused. He recovered and remained well for eight years, pursuing his employment. Then he had jaundice, dark-coloured urine, and pale stools, but no pain. He recovered health for a further two years, when (1922) jaundice and dark urine returned, and this time there was pain with tenderness over the lower part of enlarged spleen (? result of blow). The table of findings shows that this patient's bone marrow was holding out; but note how a simple operation put this red cell count down (Table V).

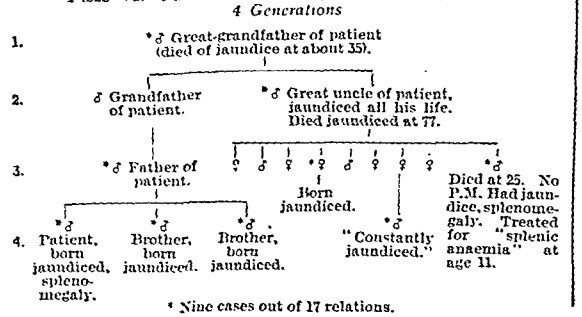
Fragility

13/6/22: Haemolysis of patient's red cells commences at 0.5 saline.
17/12/24: Haemolysis of patient's red cells commences at 0.6 saline.
17/11/26: Haemolysis of patient's red cells commences at 0.55 saline.
Urine.—14/6/24: Much urobilinogen present. *Wassermann reaction.*—14/6/24: Negative.

On questioning W. G. it appeared that he had a yellow tinge as a baby. "My brothers and myself," he said, "were born with jaundice." Thanks to Dr. Harvey Francis, the familial character of this disease in W. G.'s family is well illustrated.

TABLE VI.—*Familial Acholuric Jaundice—9 Affected in 4 Generations*



* Nine cases out of 17 relations.

HAEMOLYTIC ICTERUS IN LATER LIFE

It will be convenient to study next certain cases of haemolytic icterus in later life, as they represent end-results.

Mrs. Labourne, aged 53, was admitted to hospital with manifestations of anaemia so severe as to make it obvious that her life was in danger—pallor, faintness, dyspnoea, oedema of feet; there was a faint icteric tinge; her spleen was enlarged to a level below the umbilicus; liver just palpable; no enlarged glands. Her blood count was as follows:

Red blood cells, 2,000,000; haemoglobin, 26 per cent.; colour index, 0.65; white blood cells, 8,400; 3 normoblasts and 2 megaloblasts seen in counting 200 white cells. Poikilocytosis, anisocytosis, polychromatophilia, and punctate basophilia present. Anisocytosis very marked, and a notable increase in the larger variety of red cells. Wassermann reaction, negative; blood urea, 0.048 per cent.; fragility, haemolysis up to 0.75; van den Bergh reaction, direct and indirect positive; urine, trace of albumin, no bile.

This illness commenced three weeks before, and ended in death ten days after, admission to hospital. For eighteen years prior to this illness the patient had lived an ordinary life, except for occasional attacks of abdominal pain and vomiting, no doubt due to gall-stones. She had borne children and had done her domestic work. Further investigation disclosed that in girlhood she had been yellow, and that she and her sister were teased at school on account of this and called the "yellow sisters," though they were both well and active. This patient had lost her jaundice, while her sister retained it. In the year 1890, at the age of 17, Mrs. Labourne suffered for three years from severe anaemia—faintness, pallor, dyspnoea, oedema of feet; heart normal, liver and spleen were both much enlarged; red cell count was 1,400,000. A year or two after there occurred the first attack of abdominal pain. In 1909 the patient was admitted with shivers, fever (103° F.), and jaundice. At the same time she was very pale; her spleen extended to the iliac spine, and the red blood count was 800,000, normoblasts and megaloblasts being present. Her case was then diagnosed as pernicious anaemia, but after a while she improved and returned home. After this she was relatively well for twenty years, and then came the fatal attack of haemolytic anaemia. There will be further reference to this case when pathology is being considered.

Mrs. P.—This woman, aged 55, the sister of Mrs. Labourne, had to be traced to her home. She admitted no disabling illness. Since she was a "yellow sister" in childhood she had remained yellow more or less ever since, but never deeply so. About the age of 30 she had a nagging pain in the left upper abdomen, worse when up, and she herself felt a lump in that position. She was then liable to periods of dyspnoea, weakness, palpitation, etc. But she has lived her life, has had nine pregnancies, and has seven children alive, none of whom are yellow. At the time of her discovery in 1927 she showed slight jaundice and pallor, and had a normal heart.

Red blood cells, 2,900,000; haemoglobin, 32 per cent.; colour index, 0.55; white blood cells, 9,520; 1 normoblast in 200 white cells. Poikilocytosis and anisocytosis present. Wassermann reaction negative.

A notable blood picture, this, for a woman living an ordinary life.

The record of these sisters is complete and informing. Mrs. Labourne in her girlhood showed acholuric jaundice, and probably from the first had a low red blood count due to haemolysis; and a workable balance was only maintained by over-production on the part of the bone marrow. When she was 17 the marrow became exhausted, and the patient suffered for three years from severe anaemia, afterwards recovering equilibrium. In 1909, at the age of 36, she was thought to have pernicious anaemia. There followed eighteen years without disabling illness, and then came a short and fatal attack of haemolytic anaemia at the age of 53. Note how the clinical picture changed; at one time jaundice, and at another anaemia, was the outstanding feature. The sister, Mrs. P., has had to combat a less powerful haemolysis, and is still active; but a similar end probably awaits her.

Mrs. "Ford," aged 65 in 1926, an old lady whose father, daughter, and grandson also had haemolytic icterus, illustrates the frequent association of cholecystitis and cholangitis with this condition, and, when from age or severity of symptoms, both gall-bladder and spleen cannot be operated upon at the same time, the importance of deciding which operation should have priority. This patient had in her youth mild jaundice, varying in degree and probably of haemolytic origin, for her spleen was known to be enlarged. As time wore on, the jaundice picture altered and suggested cholecystitis. At the age of 51, in 1912, the gall-bladder was drained and calculi were removed. Thereby the pain disappeared, but jaundice persisted. The unwisdom of not removing the large spleen shortly thereafter is obvious. A few years later, when aged about 65, haemolytic anaemia in the shape of breathlessness and palpitation made itself manifest, and the blood picture showed 3,384,000 red cell count, the fragility was 0.6 for commencing haemolysis, the van den Bergh test showed a negative direct and a positive indirect reaction, and there was no bilirubin in the urine. A year later the jaundice increased, the van den Bergh direct reaction became positive, and bile pigment appeared in the urine; henceforth the case resembled more the picture of cholangitis. The red cell count was now 3,050,000, and the reticulocytes only 0.6 per cent., showing that there was but little fight left on the part of the bone marrow. Finally, it was decided to operate on the cholangitis; this was done, but, as a preliminary, after every care in typing, blood transfusion was performed. There followed a gradual deepening of the jaundice to a dark olive-green colour. Death ensued. The patient would have been better without the transfusion. This occurrence of severe jaundice following transfusion again finds illustration in the next case.

Mrs. "Bass."—Aged 44, admitted on January 11th, 1928, under Dr. Leyton, for whose permission I am indebted. There was here a doubtful history of icterus early in life; at the age of 13 the patient had been treated for chlorosis. She had had fourteen children, of whom thirteen died at or soon after birth. The last and fatal illness, at the age of 44, lasted nearly six months, and was characterized by increasing anaemia, an icteric tint, failure of appetite, and later loss of flesh. The spleen was enlarged nearly to the umbilicus; the liver was just palpable. Lungs clear; heart, soft systolic murmur at base; blood pressure 140/75; small haemorrhages in right fundus; urine cloudy with albumin; urobilin ++; *x*-rays of bones, normal.

TABLE VII.—"*Mrs. Bass*."

Date	R. B. C. c.mm.	W. C. c.mm.	Hb %	Index	Small Lymphocytes %	Reticulocytes %
11/1/28	1,600,000	8,000	33	1.03	31.0	30.0
17/1/28	1,600,000	9,000	34	1.06	20.5	43.4
23/1/28	1,600,000	8,500	32	1.0	27.5	65.2
4/2/28	1,400,000	9,300	28	1.0	29.0	
26/1/28	2,000,000	10,500	40	1.0	31.0	51.4
5/3/28	1,600,000		35			
8/3/28	1,900,000	11,500	39	1.02	9.0	48.5

11/1/28 33 normoblasts in counting 200 white cells
4/2/28 78 normo., 8 megal., 5 micro. in 200 w. cells
26/2/28 14 normo., 4 megal., in 200 white cells
5/3/28 41 normo., 16 megal., in 200 white cells
} Poikilocytosis, anisocytosis, and polychromatophilia in all instances marked.

16/1/28 *Van den Bergh reaction*: Direct negative. Indirect positive.
14/2/28 Strong biphasic reaction after first transfusion.
5/3/28 Strong biphasic 4.8 units
5/3/28 *Fragility* reached 0.82. Wassermann reaction negative.
5/3/28 *Cholesterol*: 157 mg.
5/3/28 *Test meal*: Free HCl absent. Total acidity 0.22.

The patient received three blood transfusions during the last sixteen days of her life: (1) 350 c.cm., (2) 600 c.cm., and (3) 500 c.cm. The blood group was No. 2. Each transfusion was followed by pyrexia (up to 104° F.), vomiting, diarrhoea, and deepening jaundice. Towards the end there was increased anuria, and two days before death (March 28th, 1928) only three ounces of urine were passed. This anuria has been shown by Baker and Dodds[29] to be due to the blocking of the kidney tubules by masses of acid haematin pigment.

Here, then, is a second case which suggests caution in the employment of transfusion of blood in this disease. It will be noted also how some of the severe cases are almost identical in their pictures to pernicious anaemia (for example, Labourne and Bass).

PSEUDO-ARGYLL ROBERTSON PUPILS WITH ABSENT TENDON REFLEXES

A BENIGN DISORDER SIMULATING TABES DORSALIS

BY

W. J. ADIE, M.D.ED., F.R.C.P.

PHYSICIAN, CHARING CROSS HOSPITAL AND ROYAL LONDON OPHTHALMIC HOSPITAL; PHYSICIAN TO OUT-PATIENTS, THE NATIONAL HOSPITAL FOR NERVOUS DISEASES, QUEEN SQUARE

I wish to draw attention to a benign symptomless disorder characterized by pupils which react on accommodation but not to light, and by absent tendon reflexes.

Five of the six cases I am about to describe came under my notice in the course of a few weeks; the condition therefore cannot be very rare. Though harmless in itself it merits recognition because it is often mistaken for a manifestation of syphilis of the nervous system, with unfortunate consequences for the patients and their families.

CASE I

A woman, aged 36, was admitted to the Hospital for Tropical Diseases under the care of Dr. G. Carmichael Low for an "overhaul" on her return from abroad. Physical examination and routine laboratory tests revealed no evidence of disease apart from the neurological signs that concern us here. There was nothing in the family or personal history to explain these signs. Ten years ago she noticed that her pupils were unequal. On examination I found pupils of moderate size, the right just larger than the left, which was slightly oval; neither reacted to light, direct or consensual; both contracted fully on convergence, but the movement was remarkably slow; after the effort to converge was relaxed they remained small for several seconds, then dilated very gradually to their original size. All the tendon reflexes in the upper and lower limbs were completely abolished. There were no other signs of organic nervous disease. I knew that this myotonic pupillary reaction had nothing to do with syphilis, but had never seen or heard of it in association with absent tendon reflexes. I reported as follows: "A most unusual case; I prefer not to make a diagnosis; the condition is benign, and should not prevent her from returning to her work abroad." After her discharge, Dr. Low kindly allowed me to consult the hospital notes, and I found that Wassermann's test had been done on the blood and cerebro-spinal fluid with negative results.

CASE II

A woman, aged 23, attended hospital because her brother, an optician, had found that she had Argyll Robertson pupils. She was admitted to the National Hospital for investigation. She knew "what they thought," and was greatly distressed. With the first case in mind I promised her that she should leave the hospital with the stigma removed. Apart from the special signs, nothing of importance was discovered in the course of a thorough routine investigation. The following observations were made: the pupils were unequal, right 3½ mm., left 3 mm.; the right was irregularly oval with the long axis vertical, the left regularly oval with the long axis horizontal. The reaction to light was completely absent in both; the reaction on convergence was present in both, but was abnormal; the contraction was delayed and proceeded slowly until the pupils reached pin-point size. When the effort to converge was relaxed they dilated very slowly to their original size. The knee- and ankle-jerks

were completely absent. These observations were confirmed repeatedly by myself and my colleagues. The Wassermann reaction was negative in the blood and cerebro-spinal fluid. The report on the fluid was as follows: clear, colourless; no cells seen; total protein 0.035 per cent.; Nonne-Apelt and Pandy reactions negative; Lange's colloidal gold test, no change (Dr. J. G. Greenfield).

CASE III

A young man, now aged 32, was brought to me twelve years ago by his sister, a medical student, who discovered that he had Argyll Robertson pupils. I found that his knee-jerks were absent, and thought that he was a case of congenital tabes. He came to see me recently about another matter, and I went into his family and personal history and made a complete physical examination. Nothing apart from the neurological signs suggested syphilis, congenital or acquired. His general health was good. The pupils were moderate in size and unequal, right larger than left. The right was totally inactive to light, the left reacted very feebly. On convergence both pupils contracted very slowly to pin-head size, then dilated still more slowly when he looked into the distance. He had noticed himself that the pupils varied in size from time to time. All the tendon reflexes in the upper and *lower limbs* were absent. There were no other neurological signs. He has submitted to several tests of the blood and cerebro-spinal fluid, all with negative results.

CASE IV

A woman, aged 45, attended the Royal London Ophthalmic Hospital for glasses and was referred to me by Mr. Foster Moore, who had noticed the abnormal pupils. There was nothing worthy of note in the family or personal history. Her general physical condition was good. Vision improved to 6/9 right, 6/18 left; no optic atrophy (Mr. Foster Moore). The pupils were unequal; right 3 mm., left 2½ mm. The left pupil did not react to light; on convergence it contracted slowly but fully, and maintained its smaller size long after convergence had ceased; it then dilated very gradually. The right pupil contracted feebly to light, slightly better on convergence; the contraction was not slow or unduly maintained. The knee-jerks were easily obtained and equal, but the ankle-jerks were completely absent. The Wassermann reaction in the blood was negative. The cerebro-spinal fluid has not yet been examined.

CASE V

A girl, aged 17, was referred to me by Mr. Foster Moore and admitted to the National Hospital for investigation. She noticed about two years ago that her pupils were unequal, and that the left pupil varied in size from time to time. Four months ago the left pupil became permanently large; since then she has not been able to use it for close work. Otherwise she has always been in perfect health. Examination revealed no other signs except the following. The pupils were unequal; right 2½ mm., left 8 mm. They were both inactive to light; on convergence the right pupil contracted slowly to pin-point size, and when convergence ceased it again dilated very slowly. The left did not contract on convergence. The knee-jerks were brisk; for a patient of her age, and compared with the active knee-jerks, the ankle-jerks were certainly abnormally sluggish. The Wassermann reaction was negative in the blood and cerebro-spinal fluid. Report on the cerebro-spinal fluid: clear, colourless, 1 cell per c.mm.; total protein 0.03 per cent.; Nonne-Apelt and Pandy reactions negative; Lange's colloidal gold reaction 0001100000 (Dr. J. G. Greenfield).

CASE VI

In an article on the myotonic pupil in Wilbrand and Saenger's *Neurologie des Auges*, I found a reference to a case described by Gehrcke in which eye signs like those in my cases were found in a patient with "imperfect stationary tabes." The following is an extract of the case history: A woman, aged 45; right pupil inactive to light, very slow contraction and relaxation on convergence; ankle-jerks absent. There were no other signs of organic nervous disease. The family history was not given. The Wassermann reaction was negative in the blood and cerebro-spinal fluid. The Nonne-Apelt, Weichbrodt, and Pandy reactions were all negative; no increase of cells; pressure normal. Nevertheless, because the ankle-jerks were absent the diagnosis of tabes was made. This is the only case resembling my own that I have been able to find in the literature. I have not yet completed my search. (See note at end.)

COMMENTARY

It is not surprising that all of these patients with "Argyll Robertson pupils" and absent tendon reflexes were thought to be suffering from syphilis of the nervous system, congenital or acquired. The correct diagnosis can be made with certainty by closely observing the contraction of the pupil during the act of accommodation for near objects. The true Argyll Robertson pupil reacts promptly and fully, often excessively, on convergence, and dilates again as soon as the effort to converge the visual axes is relaxed. In these cases the pupils show the so-called myotonic reaction; they do not respond to light; they contract very slowly through a wide range during a sustained effort to converge; often remain small long after the effort ends, and, when they dilate again, do so slowly. They differ in other ways from the true Argyll Robertson pupil, but the above features are sufficient to distinguish them. This myotonic reaction is well known to ophthalmologists, and it has been firmly established that syphilis plays no part in its production. Mr. Foster Moore has described seven cases under the title "Non-luetic Argyll Robertson pupil," and has told me of several others he has seen. The characteristics of his cases are, he says, the complete or substantially complete inaction of the pupil to the light stimulus, the leisurely manner in which it contracts with convergence, and in which it again dilates after relaxation of convergence; the frequency with which it is unilateral; the integrity of accommodation; the absence of syphilis; the presence of knee-jerks, and the absence of signs of any nervous disease even after many years.

It seems to me more than probable that some of his cases with non-luetic Argyll Robertson pupils but normal tendon reflexes are examples of a milder form of the same benign disorder that I have described here. I think, too, that my cases are related to those described by Mr. Gayer Morgan and Dr. C. P. Symonds under the titles "A series of cases with rapid onset of unequal pupils and failure of accommodation: a forme fruste of encephalitis lethargica," and "Internal ophthalmoplegia with absent tendon reflexes." In their cases the defect was most often unilateral, the affected pupil was dilated, and reacted not at all or incompletely both to light and on convergence; further, accommodation was partially paralysed, so that visual symptoms were produced. In some of their cases the tendon reflexes were diminished or lost.

My fifth patient seems to me to provide evidence that links the three groups. In one eye her pupil was dilated and fixed, with paralysis of accommodation, as in the cases described by Mr. Morgan and Dr. Symonds; in the other eye accommodation was normal, the light reflex was absent, and the reaction on convergence was myotonic as in the non-luetic Argyll Robertson pupils of Mr. Foster Moore. My fourth case also showed a myotonic pupil on one side and a partially fixed pupil on the other. I have reason to believe that a large fixed pupil is sometimes the forerunner of a myotonic pupil. These and other more academic aspects of the subject I hope to deal with at another time. My object now is to make it known that pupils conforming to the prevailing loose definition of an Argyll Robertson pupil, and easily mistaken for the true

Argyll Robertson sign, may be found associated with loss of tendon reflexes in patients with a benign disorder that has nothing to do with syphilis whatsoever.

Note.—After this was written, Mr. Foster Moore kindly allowed me to read the typescript of his paper on the non-luetic Argyll Robertson pupil, which he read at the recent ophthalmological congress. In one of his fifteen patients with this abnormal reaction of the pupil, the knee-jerks were absent: in another they were obtained with reinforcement only.

ACUTE MASSIVE COLLAPSE OF THE LUNG FOLLOWING LIPIODOL INJECTION

BY

A. J. SCOTT PINCHIN, M.D., F.R.C.P.
PHYSICIAN TO VICTORIA PARK CHEST HOSPITAL; PHYSICIAN, WEST LONDON AND HAMPSTEAD GENERAL HOSPITALS

AND

H. V. MORLOCK, *M.C.*, M.D., M.R.C.P.
PHYSICIAN TO OUT-PATIENTS, VICTORIA PARK CHEST HOSPITAL, MILLER AND HAMPSTEAD GENERAL HOSPITALS

In view of the more general use of lipiodol injection of the bronchial tree as an aid to the diagnosis of pulmonary disease and of the increasing importance which collapse of the lung is assuming in the etiology of acute pulmonary conditions, this case is of special interest.

The patient, a healthy-looking young man, aged 18, was sent to us because of a pain in the side, which he had had for two months and which his doctor suspected as a pleurisy. The pain was sufficiently severe to prevent him breathing deeply. There were no physical signs except feeble breath sounds. He was admitted to hospital for further investigation to exclude the possibility of fibrosis with bronchiectasis. A simple skiagram of the chest showed no abnormality. A lipiodol injection of the bronchial tree was done by the crico-thyroid route. To suit the convenience of the hospital this procedure was carried out on the *x*-ray table. The following points are to be noted:

1. The injection was done on the *x*-ray table, the film being in position, and the time from the injection to record of the skiagram was considerably less than five minutes, probably only three minutes.
2. At the time of the collapse the patient showed only slight respiratory distress. The physical signs present were diminished movement, slight impairment of percussion note, and a considerable diminution of the air entry over the affected side of the chest.
3. The speed with which recovery took place according to the skiagraphic records.

Jacobaeus, Selander, and Westermark,[1] in their paper on acute massive collapse of the lung, record four such cases in which the injection of lipiodol was followed by collapse of the lung. These were from a series of eight patients with normal bronchi whom the authors were injecting for purposes of investigation, and it is somewhat astonishing that they should have found so high a proportion in whom the injection was followed by massive collapse.

In our case the bronchi were normal, but in a previous investigation on the subject of dry haemorrhagic bronchiectasis we occasionally injected lipiodol into a patient with normal bronchi, yet this is the first case of massive collapse from this cause that we have seen. In a series of many hundreds of lipiodol examinations for many varying pulmonary conditions at Victoria Park Hospital no such case of massive collapse has occurred.

A point of considerable interest is the length of time between the injection and the collapse. In Jacobaeus's cases ten to fifteen minutes elapsed between the injection and the skiagrams. In our case the time between the injection and the record by skiagram was probably not more than three minutes. That is to say, the collapse was practically immediate. Coryllos, Birnbaum,[2] and also Lee, Radwin, Tucker, and Pendergrass[3] produced massive pulmonary collapse in animals by plugging a bronchus with a balloon. The collapse was not complete till six hours later. The latter authors also obstructed a bronchus with a solution of gum arabic, causing complete collapse in four hours. The time taken for the collapse to disappear in Jacobaeus's cases was from two and a half to nine hours; in our case there was considerable improvement in half an hour, and complete recovery in twelve hours.

ETIOLOGY OF MASSIVE COLLAPSE

Morison,[4] in an instructive article reviewing massive collapse, groups the four main theories of etiology as follows:

1. Failure of the respiratory power of the lung playing an active part (Pasteur).
2. The mucus plug theory (Jackson, Lee, and others).
3. Reflex spasm of muscles of the bronchioles (Bradford, Sante, and others).
4. Inflammation of the crus and one-half of the diaphragm or of pleural membrane covering it (Charlton Briscoe).

Clinical experience goes to show that Group 1 probably has least influence in the production of the condition. A mucus plug, acting either as a complete obstruction or as a check valve (in which case the air may be exhausted much more rapidly), may indeed be a factor in the causation of post-operative collapse, but cannot cause this instantaneous collapse.

Reflex spasm, involving the walls of the bronchioles, is the only way in which the lung could be so rapidly emptied of its air. Jacobaeus put forward this view in explanation of his four cases following lipiodol injection, concluding that spasm of the bronchi and bronchioles squeezed out most of the air in the bronchial system, leaving only the alveolar air to be absorbed. In support of this view he claimed that in two cases of his the bronchi were seen to be distinctly smaller in the state of collapse than later when the collapse had passed off. This scarcely seems a fair contention, as one would expect that in a collapsed lung the bronchi would naturally be smaller.

Sante[5] incorporates the first three views in his theory that the condition is due to simultaneous inhibition of the cough reflex by some toxic or reflex stimulus, with an impairment of the respiratory muscles, caused either by a defensive immobilization or by paralysis from a toxic neuritis. This permits secretion to accumulate and block the bronchus, atelectasis resulting.

In this explanation the mucus plug is the final cause of the atelectasis. As has already been recorded, an atelectasis produced by a mucus plug in animal experiments required four to six hours to develop, but in these animals the inhibition of the cough reflex and the impairment of the respiratory muscles were not present. In cases of immediate collapse, we would suggest that it is the inhibition of the cough reflex and the impairment of the respiratory muscles which produce a reflex spasm of the bronchi and bronchioles (as suggested by Jacobaeus), thus actively expelling the air from the bronchial system, while the mucus plug acts as a check valve, not allowing air to re-enter.

HOMOLOGOUS ANTIPNEUMOCOCCAL SERUMS IN THE TREATMENT OF LOBAR PNEUMONIA

BY

RICHARD R. ARMSTRONG, M.D., F.R.C.P.

AND

R. SLEIGH JOHNSON, M.D., M.R.C.P.

Serum treatment of lobar pneumonia is no new thing. Fresh interest has been aroused in this subject during recent years by the use, in America, of the "Felton" concentrated antipneumococcal serum. Reports have appeared very recently, from Edinburgh and Glasgow, of the therapeutic application of the concentrate in cases of lobar pneumonia due to infection by the pneumococcal Types I and II. It has been our good fortune, thanks largely to the Medical Research Council, to try this new remedy during the past few months. It will be evident from the account which follows that we believe the antipneumococcal serum to be a remedy of the first importance. There is, however, a strong body of opinion, concerned not so much with clinical evidence as with crude mortality statistics, which inclines to doubt this conclusion, particularly in view of the fact that the mortality, in cases due to Type II infection, has not been shown to be materially reduced. On our part, we seriously doubt whether crude mortality experience affords a true criterion by which the success of this treatment may be judged, for every physician will agree that a great variety of conditions may prejudice the course of pneumonia and lead to the death of the patient, irrespective of the pulmonary condition.

THE FIELD OF INQUIRY

The field of inquiry was limited at first to St. Bartholomew's Hospital. It soon became apparent that the number of cases likely to be available there was small. Grateful thanks are due to the Medical Officer of the London County Council for permission to work, since mid-January, in the Council's highly efficient and well-equipped hospitals at Mile End and Bermondsey; acknowledgements are due to the medical superintendents at each of these hospitals for unrestricted access to cases, and to the members of their medical and nursing staffs for loyal co-operation. Foremost among our allies has been Dr. Gordon Sears at Mile End, whose balanced judgement of the clinical aspect of treated cases has been of superlative value to us. Some cases at the Victoria Park Chest Hospital were also treated.

RAPID METHOD OF DETERMINING PNEUMOCOCCAL TYPE

So far as we know at the time of writing, the basis of our inquiry differs from that adopted in any other investigation of the kind in this country, in that we have determined before administration of serum the serological type of pneumococcus responsible in each case. The method has already been described in a recent number of the *Journal* (February 7th, p. 214). In brief, a mouse is inoculated with the patient's sputum; in four hours or less the animal's peritoneal cavity is explored by acupuncture. The exudate so obtained is mixed on a slide with an equal volume of each of the type agglutinating serums and examined under the microscope. A characteristic change in the appearance of the pneumococci takes place in the case of a positive reaction. The cocci become conspicuously enlarged; if present in considerable numbers they speedily agglutinate. The reaction is quite characteristic and free from ambiguity. Thus in no instance was serum administered unnecessarily, as happened in other hands, in cases due to infection by nondescript pneumococci.

METHOD OF ADMINISTRATION: SENSITIZATION

The most important consideration in serum treatment must be early administration of the largest convenient dose. In the first instance, intravenous medication is essential; by no other route may the desired result be attained. The suggestion of intravenous serum therapy conjures up the dread of anaphylactic shock. This dread is imaginary rather than real; it ceases to be of importance if the simple procedure be observed of keeping a hypodermic syringe containing 1 c.cm. of 1 in 1,000 adrenaline solution always in readiness before giving the serum. One of our patients had a very severe anaphylactic reaction, but this was promptly controlled by subcutaneous adrenaline. It is the rule that first reactions are the most severe, and that subsequent inoculations progressively provoke less shock; the same generalization applies to the rigors and other forms of disturbance of less moment which are occasionally seen. The elaborate tests for sensitization by dropping serum on to the eye or by squirting it into the skin are, we venture to state, as unnecessary as they are apt to be misleading.

VARIOUS SERUMS USED

The serums used have come, partly by gift and partly by purchase, from different sources; our supplies have been very strictly limited. Our gratitude for the gifts is not the less sincere from the fact that we are not at liberty to divulge the donors' names. A concentrate containing antibodies against the pneumococcal Types I and II prepared by Parke, Davis and Co. or by Lederle was used. A similar concentrate, effective only against Type I pneumococcus, from the Wellcome Laboratory, was also given. These concentrates are alike prepared by the Felton method, being derived from the serum protein of immunized horses by precipitation of the euglobulin fraction, associated with the specific antipneumococcal antibodies, in a large volume of distilled water, the precipitate being collected and redissolved. The protective values, per maker's dose (the contents of each phial supplied), of the three concentrated serums used have been accepted for the purpose of this inquiry as approximately equal, a practice which has been justified by the clinical results.

An unconcentrated (horse) serum, Type I, supplied from the Wellcome Laboratory, was also used by us in four cases. This serum was of exceptionally high titre, and was said to be of nearly two-thirds the protective value of an equal volume of the same firm's concentrate. The preparation of concentrate is both difficult and costly, so that therapeutic trial of this unconcentrated serum was not without point. Seeing that the primary object of treatment is administration of the largest possible quantity of antidote at the earliest moment, the conditions of the experiment are scarcely satisfied by the use of the unconcentrated remedy. This view was confirmed by experience in two cases, although in two others of less severity the results were all that could be desired. We concluded that unconcentrated serum should be used only in early cases of moderate severity or in adolescents whose illness it might be desired to abort.

DOSAGE

The considerations which have determined the size and spacing of doses must now be discussed. The reports from Scotland state that a wide range of doses from a minimum of one dose to a maximum of twenty-six was employed there, with an average of six doses per case. Our impression of the system adopted in America is that there five doses per case represented the average requirement.

Although in many cases improvement follows intravenous injection of the remedy, without any disturbance

of the patient's general state, rigors are of frequent occurrence, particularly in cases treated early in the disease. The severity of the reaction seems proportional to the dose. We find that the contents of two phials (a double dose), approximately 20 c.cm. volume, administered with an ordinary 20 c.cm. glass or Record syringe, is generally the maximum desirable ; this dose should be given slowly and cautiously at first. With a sensitive patient or in one subject to bronchitis or asthma, it is better, in our experience, to reduce the dose to one phial. The same conditions apply to the spacing of doses, for if the reaction be severe, six hours is all too short an interval ; eight hours is preferable, and in early cases we have been quite content to begin with a double dose morning and evening, a manœuvre very convenient to the practitioner, who is likely in any event to see his patient twice a day during the acute stage of the pneumonia. Our standard procedure has therefore become: in early cases, an initial double dose followed by a second similar dose, then a final single dose; administration at eight- to twelve-hour intervals ; in later cases, three double doses and a final single dose. These doses have generally sufficed, but it must not be supposed that we have been constrained by any arbitrary considerations, as in every case the clinical indications have been our guide. Thus, in some, three doses have aborted the illness ; while in one case of exceptional severity nine were given. In general terms, however, if a favourable effect does not follow a course of seven doses, we seriously question whether benefit is likely to follow prolongation of serum treatment.

Analysis of Cases

Clinically typical cases of pneumococcal primary lobar pneumonia in adult men and women have been exclusively selected for study or treatment. The series includes no children or old people. The incidence of the pneumococcal types of infection is shown in the table.

Incidence of Pneumococcal Types

Type I		Type II		Type III	Nondescript	Total Cases Investigated
Treated	Untreated	Treated	Untreated			
16	10	10	5	6	47	80

It is generally held that cases due to Type II pneumococcal infection are more severe and more resistant to treatment than cases due to Type I. While admitting this contention, we have not perceived, in the admittedly limited number of cases of each infection treated by us, any marked difference in the response to serum treatment, as we have obtained equally good results in both instances. Let it be strongly emphasized that we have abstained from serum treatment in all cases, irrespective of the pneumococcal type of infection, which were obviously mild and progressing in a favourable manner ; moreover, we have never intervened later in the illness than on the sixth day. The results appear in the tabular analysis which follows, and illustrate the supreme importance of early treatment.

Analysis of Twenty-Six Treated Cases. Types I and II

Day Treated	Result		
	Aborted	Improved	Uninfluenced
Second... ...	6	—	—
Third	3	4	1
Fourth	1	3	—
Fifth	—	3	1
Sixth	—	2	2

Symptomatology of Serum-treated Cases

The effects of treatment by concentrated antipneumococcal serums may be conveniently summarized under two headings: (1) conspicuous immediate results ; (2) characteristic general effects.

Conspicuous Immediate Results

Shock.—We noted in six of our twenty-six treated cases that the first dose of serum was followed by respiratory distress, varying from rapid and shallow breathing, with or without a sense of constriction in the lower chest or round the waist, to urgent dyspnoea and cyanosis, observed in two cases of the series. At the same time, the pulse became frequent and ill-sustained or for a short time barely perceptible at the wrist. The patient's face was livid, the lips colourless, and the eyes sunken. At this moment adrenaline was given, and was followed in every case by rapid cessation of the alarming symptoms. The onset of shock was from five to fifteen minutes after the serum injection ; the phase of discomfort lasted up to half an hour if adrenaline was not administered.

Rigors.—In twelve cases a rigor or shivering attack followed the first injection, the highest level of temperature reached being 105.8° F. In ten cases, a rigor, with lower maxima, followed the second dose ; in four only, the third or subsequent doses. Our experience consistently proves that a brisk rigor following the injection is of favourable import. This phenomenon was specially observed when the Parke Davis concentrate was used, and also with a particular batch of serum concentrate from the Wellcome Laboratories.

Sweating.—Profuse sweating, a constant accompaniment of spontaneous crisis in lobar pneumonia, does not occur with the same frequency when the clinical course of the disease is interrupted by serum treatment, nor is defervescence, following a rigor, necessarily associated with sweating. Thus only six of our patients sweated after the first dose of serum and ten after the second. The presence or absence of sweating gave us no definite indication as to the probable course of the illness.

Cyanosis.—Cyanosis is a characteristic feature in almost every case of lobar pneumonia. Most clinicians believe that this bears no exact relationship to the extent of consolidation in the lung. Indeed, cyanosis is frequently observed long before consolidation has taken place. One of the most remarkable effects of the serum treatment is improvement in the patient's colour. Sometimes after the first dose, usually after the second, the normal complexion returns, so that one may perceive, even at a distance from the bedside, the disappearance of the pneumonic facies. This change often occurs before the pulse and respiration rates have subsided, and bears no relation to the physical signs of consolidation, which are usually better defined than before treatment, corresponding to the course of the inflammatory process in the lungs. We submit that there is considerable probability that cyanosis in lobar pneumonia is a toxic phenomenon due to damage to the alveolar walls by pneumococcal products ; we claim this important evidence of the benign effect of serum treatment as proof of its highly specific action. An analysis of treated cases shows that cyanosis vanished in seventeen cases, was lessened in five, and remained unchanged in two cases which ended fatally. Two other cases were profoundly anaemic ; therefore the characteristic cyanotic tinge was not to be expected. The respiration rate usually falls more gradually after serum treatment than after true crisis More conspicuous is the disappearance of respiratory distress and cessation of the pneumonic grunt.

The Mental State.—Sleeplessness causes as much anxiety as any symptom of pneumonia to the physician in

attendance. Among other mental disturbances are restlessness and anxiety, with confusion of mind and even active delirium. The effects of serum are consistently beneficial in this respect, affording conspicuous relief to the patient. Natural deep sleep for some hours, without the aid of hypnotics, followed the first dose of serum in eleven of our patients, and in seventeen the mental state improved. Of the group of twenty-six cases, nineteen patients slept after the second dose and in twenty-two the mind became clear and composed. The exceptions were afforded by two fatal and two anaemic cases. Proof of the extreme deprivation of rest suffered in the untreated case of lobar pneumonia lies in the well-known fact that after natural crisis the patient will often sleep for days. No such exhaustion was apparent in our cases treated early; more than once, these patients have personally testified to their intense satisfaction in having enjoyed a night's good rest after the serum.

Albuminuria.—Among the consequences of the pneumonic toxaemia is albuminuria. Urinary tests were not made in every case, but in a number observed daily the disappearance of an albuminuria, often gross, was a constant sequel of treatment. In any event, one of the most frequent subordinate evidences of recovery from the acute stage of lobar pneumonia is diuresis; this flow is expedited by giving serum.

Characteristic General Effects of Serum Treatment

Whereas it is fair to state that the illness in cases of primary lobar pneumonia untreated by antipneumococcal serum becomes increasingly more serious up to the time of crisis, when within a few hours the picture changes, in cases treated early by the Felton concentrated antipneumococcal serum symptoms progressively abate after the inoculations. In cases in which treatment is begun later the effects are not dissimilar to those observed in normal subsidence by lysis. Slight irregular fever following a course of serum is not infrequent, this happening most often in cases treated late and in those in which scattered bronchitis accompanies the pneumonia. This slight fever, occurring when the height of the disease is past, must not be considered of adverse clinical significance or as evidence that the remedy is inadequate. Success or failure in the serum treatment of lobar pneumonia is to be gauged by the patient's improved general state, in particular by the disappearance of the so-called "toxaemic" symptoms rather than by slavish concentration on minor vagaries in his temperature. Analysis of the 26 treated cases shows that 11 became and remained afebrile following the last intravenous dose of serum, an irregular slight fever persisted for a few days in 12 others, while in 3 cases the temperature did not respond.

The pulmonary condition is not the only consideration in lobar pneumonia. At least an equal measure of attention must be paid to the heart and the general state of the patient. The importance of adequate rest has already been emphasized. We do not propose to digress into a discussion on the control of the pulse rate, although we incline to favour tincture of digitalis, given early in the illness, as a conservator of cardiac energy. We are not averse to the giving of alcohol (whisky or brandy) as required. Cane sugar or glucose may be taken freely, being a food which is easily assimilated and speedily utilized. Returning to serum treatment, this undoubtedly has favourable influence on the alimentary system. After the first, usually, almost invariably after the second, dose of serum, the tongue becomes moist and cleaner; appetite rapidly returns. It is hardly possible to describe the astonishment we felt on finding a patient who had suffered violent anaphylactic shock and a severe rigor, following serum administration at 11 o'clock in the forenoon, sitting up in bed at 6 o'clock the same evening, when his final dose of serum was due, enjoying tea, bread-and-butter, and a boiled egg. This occurred on the fifth day of an illness which was exceptionally severe before treatment was begun. The inevitable loss of flesh and the asthenia which is a consequence of pneumonia are stayed or prevented if serum is given early in the disease, as on the one hand the illness is aborted and on the other the patient is not called upon to sustain the effects of days of fever and starvation. Hence convalescence is greatly shortened and assisted.

THE GENERAL EXPEDIENCY OF SERUM TREATMENT

It is appropriate to refer to certain essentially practical aspects of the results of serum treatment. Unquestionably lives are saved, the patient's sufferings are relieved, and the acute anxiety of his relatives is consequently soothed. Other more mundane considerations follow: admitting that the serum is at present costly both to make and to market, in all probability serum treatment represents actual economy. The services of both a day and a night nurse, essential for the case of severe pneumonia, may be dispensed with at an early stage; visits from the physician, twice daily or more often, soon cease to become necessary, and convalescence is so far accelerated that the wage-earner returns to work in a state of full efficiency, literally weeks before the untreated case. These considerations apply with equal force to the case of the sick in institutions and to the private patient; it would be exceedingly interesting to offset the expenditure on a course of serum treatment, say ten to fourteen guineas, with a virtual guarantee of speedy recovery, against the alternative cost of a long and serious illness, with prolonged convalescence, in the untreated case.

SERUM TREATMENT OF LOBAR PNEUMONIA COMPLICATING PREGNANCY

Pregnancy is occasionally complicated by lobar pneumonia, and miscarriage or abortion not infrequently ensues. Two pregnant women were treated by us. One was aged 27 years, with a recrudescence of nephritis, blood and much albumin (1.5 per cent.) in the urine, pregnant 2½ months; the other had a straightforward pregnancy of 7½ months. In neither case was the pregnancy disturbed, while the nephritic woman left hospital ten days later with only a "cloud" of albumin in the urine and no blood.

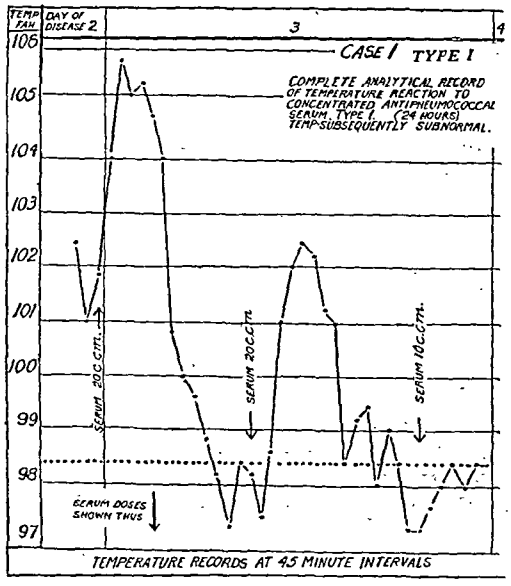
INFLUENCE OF SERUM TREATMENT ON THE PHYSICAL SIGNS

We deny, on the basis of our experience, that serum treatment causes delayed resolution of the consolidated lung. We are not entirely in agreement with those who assert that the course of events in the lungs is uninfluenced. Considering cases treated within the first three days from the onset, the physical signs, indicating the course of the inflammatory process in the lung, undergo rapid change, corresponding with the effect of serum in relieving symptoms. Signs of the first stage of resolution, weak or absent breath sounds, replacing bronchial breathing over the consolidated areas, and signs of the second stage—namely, the appearance of the coarse, moist rales found during resolution—follow on successive days, accompanied by rapid diminution of percussion dullness. Correspondingly, the typical viscid, blood-stained, rusty, highly albuminous sputum of early pneumonia, containing scanty alveolar and bronchial epithelial cells, changes in a day to a loose, purulent expectoration, full of polymorphocytes.

These rapid changes are to be likened, in our experience, to those which quickly succeed each other in the very mild cases of lobar pneumonia (albeit due to the pneumococcal Types I and II) occurring in adolescents and to infection

by unclassified strains of low virulence in adults. This class of case commonly ends by crisis on the third day of illness. An important difference exists between these mild cases and the typical severe cases in adult men and women selected by us for treatment—namely, that in the mild untreated cases physical signs are limited in extent. Ample evidence of the potential severity of our early cases was afforded by extensive consolidation of one lung, often accompanied by physical signs on the opposite side, which sometimes progressed, despite treatment, to an area of definite consolidation.

With few exceptions our patients, treated early, complained of pain, frequently at both bases, often referred to the shoulder or abdomen on the side where consolidation was most extensive; pleural friction was to be heard with the stethoscope. We noted a difference in this respect from the behaviour of untreated cases at the same stage of the disease, and suggest the following explanation. With alleviation of symptoms and restoration of lucid perception, the patients undoubtedly become aware and grumble at lesser discomforts, which are ordinarily masked by the severity of the illness and the confused mental state usual at this stage. Moreover, it is not improbable that the pleurisy is arrested in the so-called "dry" stage before the gross "buttery" fibrinous exudate of late pneumonia has had time to develop. Movements of the chest wall are very limited on the affected side in pneumonia; the artificial arrest of inflammation by serum undoubtedly relieves this muscular spasm, and so permits a friction between the roughened surfaces of the visceral and parietal pleura. The condition lasts at most two to three days, and is relieved by local applications—a linseed poultice or antiphlogistine.



CASE 1.—Male, 38. Onset, sudden; symptoms, typical; signs, consolidation of whole right lower lobe, general bronchitis; dramatic improvement after first dose of serum; shock, absent; resolution rapid; pleural pain seventh day of disease.

These points are worth noting. We became able, as our experience grew, to reassure our patients, saying that the symptoms were insignificant and would soon pass. We anticipate that the development of new symptoms and fresh physical signs, such as pleural friction on one or both sides of the chest, might well cause apprehension in the mind of the physician, treating his first case with serum, that complications or recrudescence of the pneumonia were pending. *There is no cause for alarm.*

LATE SERUM EFFECTS

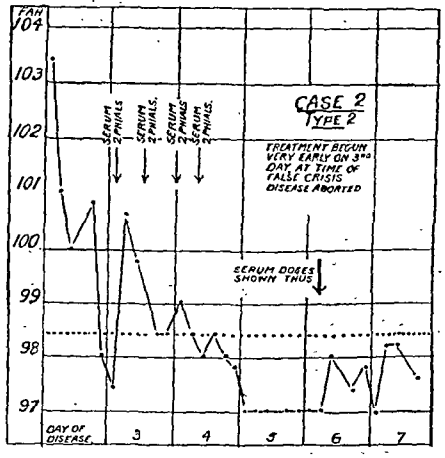
Late effects from administration of therapeutic serums of whatever kind are apt to be disconcerting to the physician, and, particularly in the case of painful or swollen joints, distressing for the patient. Nettle-rash developed in two patients, both of whom had received the unconcentrated Type I antipneumococcal serum mentioned earlier in this paper. Adrenaline injections successfully controlled the irritation. Two patients had a transitory acute arthritis, yielding at once to salicylates—one after concentrated, the other after unconcentrated, serum.

COMPLICATIONS

It is impossible to give an opinion, on the slender basis of twenty-six cases, as to any alteration in the incidence of complications such as empyema, in cases treated by antipneumococcal concentrate. A study of the very extensive American literature on the subject suggests that serum treatment does not prevent these complications.

EXAMPLES OF SUCCESSFUL TREATMENT BY SERUM

We do not question that spontaneous recovery would have occurred, in all probability, in most of our successful cases, but we strongly urge that the remarkable amelioration in the patient's condition which follows serum is more than sufficient justification for our advocacy of this treatment.



CASE 2.—Male, 32. Onset, sudden; symptoms, severe; signs, consolidation of whole right lower lobe and later of left base; marked improvement after second dose of serum; shock, considerable; resolution satisfactory; pleural friction seventh day of illness.

Considerations of space require the omission of full notes on representative cases; the reader's attention is directed to the charts, illustrating this paper, and to the accompanying legends.

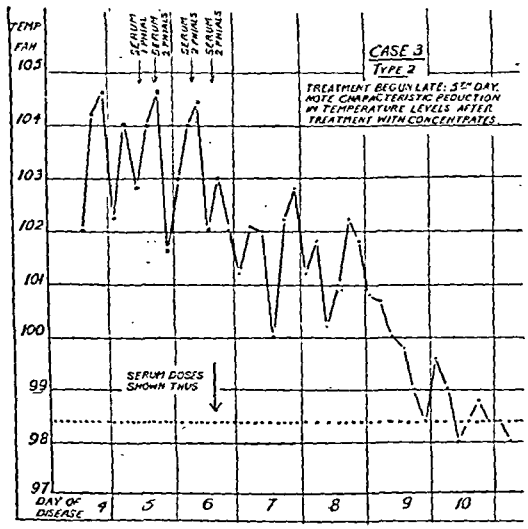
A TYPICAL CASE TREATED BY NORMAL HORSE SERUM AS A "CONTROL"

A case of Type I infection, of average severity at the time of onset, was treated by normal horse serum as a "control" with the object of deciding the possible non-specific effects of horse-serum protein. A course of seven doses, given as usual in three doses of 20 c.cm. and a final dose of 10 c.cm., were given at twelve-hour intervals, beginning on the third day. The patient became steadily worse as his illness progressed unchecked. There was relapse, due to consolidation of the opposite lung, and when the illness ended by a slow lysis, extending over the seventh to ninth days, he was left extremely debilitated, and convalesced but slowly. In fact, physical signs of consolidation in both lungs still persisted three weeks after lysis.

UNSUCCESSFUL CASES

Much stress has been laid on the high mortality in cases of pneumonia with pneumococcal septicaemia. Blood cultures have been made by us in all our severest cases, but in none has there been a positive result. We offer no evidence on this point, but wish to emphasize that the observations made in this paper apply to the sporadic form of lobar pneumonia occurring in the British Isles. It is obvious that this form is far less severe than that which prevails in New York or that responsible for the Rand epidemics a few years ago. Likewise, the small number (26) of cases treated and the method of selection —namely, the choice of (1) early, or (2) severe cases— deprives our mortality experience of significance, for the group is not homogeneous.

There were three fatal cases. One patient (Type I) apparently recovered from his pneumonia with the aid of serum, but died from the results of a surgical operation (reported in the *Journal* of April 25th, p. 701). A second (Type II), our oldest patient, a man aged 60, did not respond to serum given on the fourth day of disease.



CASE 3.—Female, 21. Onset, sudden; symptoms, severe; signs, consolidation of whole right lung and later of left base; gradual improvement after second dose of serum; shock, absent; resolution satisfactory.

Outstanding adverse features were myocarditis, chronic bronchitis, past syphilis, and alcoholism. Death occurred on the fifth day, from heart failure rather than from the lung affection. In a third case (Type II), serum given on the third day of illness was followed by marked initial improvement; misled by this apparently good result, we unfortunately stopped treatment prematurely. The patient became worse. Serum administered after an interval of forty-eight hours was ineffective, and he died.

SUMMARY

1. The course of primary lobar pneumonia, due to the pneumococcal Types I and II, may generally be aborted if treatment with the homologous concentrated antipneumococcal serum is begun within the first three days of the disease.

2. The course of primary lobar pneumonia, due to Types I and II, may be favourably influenced if treatment with the concentrate is begun on the fourth or fifth day of the disease.

3. It is doubtful whether the course of the disease is influenced to any extent if treatment is begun later than the fifth day.

4. The contents of five phials or makers' doses, estimated to contain 10,000 standard antipneumococcal units per dose, generally suffice for early cases of Type I infection.

5. The optimum dosage for cases of Type II pneumococcal infection, and for later cases of Types I and II infection, is the contents of seven phials.

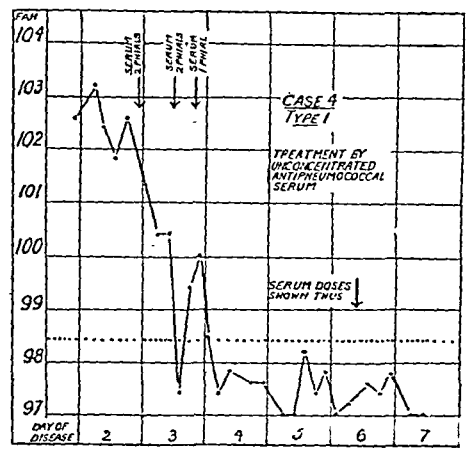
6. The intervals between doses should be not less than six hours, but may be conveniently extended to twelve hours if treatment is begun within the first three days of illness.

7. Unconcentrated antipneumococcal serums of high titre may be used with success for very early cases of moderate severity, and in adolescents.

8. The serum must be given intravenously; by no other route may satisfactory results be obtained.

9. Desensitization is unnecessary; 1 c.cm. of 1 in 1,000 adrenaline solution should be administered subcutaneously whenever symptoms of shock are apparent.

10. The intravenous administration of serum is especially effective in aborting and eliminating toxic phenomena, cyanosis, delirium, etc. The action of the serum appears to be specific.



CASE 4.—Male, 35. Onset, sudden; symptoms, typical but moderate; signs, consolidation of left base; improved after first dose of serum; disease aborted; resolution accelerated, almost complete on seventh day.

11. Considering the cases of Type I and Type II infection together, of 26 cases 18 were treated by antipneumococcal serums within the first four days of the disease. In 10 of these the pneumonia was aborted and in 7 improvement was apparent. One patient showed initial benefit, but relapsed and died. Eight were treated with serum on the fifth and sixth days; five were improved, and three uninfluenced. These results sufficiently illustrate the supreme importance of early treatment.

CONCLUSION

A final word of explanation of the form of this communication is perhaps desirable. It is a common mistake to claim too much for a new remedy; indeed, the field we have entered has been beset for years by enthusiastic advocates of a variety of medicaments. Good effects in two or three cases might be attributed to coincidence or to unconscious favourable selection, but any such influences may be excluded without misgiving when consecutive experience confirms first impressions. The accounts of treatment in America are widely scattered through the literature, and not easily accessible to most English readers. We pay homage to the workers across

the Atlantic and to those in Glasgow and Edinburgh, and pray to be excused detailed reference to the work of others; we do not wish to overload our text.

We have tried to convey to the practitioner a clear impression of what takes place at the bedside, and to guide him in dosage and in the treatment of emergencies. To those who are interested, we offer the advice to apply the remedy to the first suitable case that arises in their practice.

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

FRONTAL SINUSITIS WITH INTRACRANIAL SUPPURATION AND INVASION OF BLOOD AND CEREBRO-SPINAL FLUID BY DIFFERENT ORGANISMS

The following is a record of a case of acute frontal sinus suppuration terminating in meningitis, and presenting some unusual bacteriological features.

On April 25th, 1930, a male, aged 28, was admitted to the ear, nose, and throat department suffering from oedema of the left conjunctiva of three days' duration, limitation of eye movement, and proptosis.

On investigation there was definite tenderness over the left frontal sinus, and transillumination showed the left frontal area to be dark. X-ray examination disclosed little difference between the two sides. Next day a Howarth's operation was performed by Dr. J. S. Fraser; a little pus was present in the ethmoidal and left sphenoidal sinuses, but in the left frontal sinus there was a large quantity which, when tested, showed a *Staphylococcus aureus* infection. For three days after operation the temperature was high, and a growth of *Staphylococcus aureus* was obtained in a blood culture on April 29th. The next day abscesses appeared in the gluteal and deltoid regions. From the pus obtained by opening and draining these abscesses a *Staphylococcus aureus* was again cultured.

During the next fortnight the temperature continued to swing, and, on examination of the lungs, signs of old tuberculous lesions with definite cavities were found at both apices. The sputum contained no *B. tuberculosis*, but many organisms of the strepto-pneumococcal group. From blood culture on May 14th a very strongly haemolytic streptococcus was found. The patient improved to some extent, and blood culture a fortnight later was negative, although the temperature continued to swing. On June 4th he complained of headache and became mentally abnormal, refusing to speak but willing to do anything he was asked. The following day there developed paresis of the muscles below the left eyebrow and of the right arm. The knee-jerks were brisk and abdominal reflexes present. There was no ankle-clonus, but there was an extensor plantar reflex, a positive Kernig's sign, and some difficulty in swallowing. On lumbar puncture the cerebro-spinal fluid was turbid and under pressure, and a *Pneumococcus mucosus* was found. This was non-haemolytic, inulin-fermenting, bile-soluble, and agglutinated by Type III serum.

The patient died on June 6th. Post-mortem examination showed intradural and extradural abscesses over the left frontal lobe, with chronic osteomyelitis of the left frontal bone, and cario-necrosis of the roof of the orbit extending to the roof of the sphenoidal sinus. There was also an early well-marked leptomeningitis. On bacteriological examination of the pus from the intradural abscess two organisms were found—namely, a *Staphylococcus aureus* and a *Pneumococcus mucosus* (Type III).

The striking feature of this case is the variation of the type and origin of the infecting organism at different periods of the illness. In all, three distinct organisms were found—namely, *Staphylococcus aureus*, haemolytic streptococcus, and Type III pneumococcus. In the early stages a *Staphylococcus aureus* infection was predominant, the source of this being presumably the infected frontal sinus. Later, however, a haemolytic streptococcal septicaemia developed, the organism probably having its origin in the lung condition. Unfortunately, a more complete examination of the sputum was not carried out, as at this time the significance of this source of blood infection was not fully realized. Finally, *Pneumococcus mucosus* was found in the intradural abscess along with *Staphylococcus aureus*, while the Type III pneumococcus was alone responsible for the infection of the cerebro-spinal fluid.

I wish to thank Dr. J. S. Fraser for his kind permission to use the case notes, and Dr. W. R. Logan for his guidance in the bacteriological work.

JOHN A. BURGESS, M.B., Ch.B.,
Assistant Bacteriologist, Royal Infirmary, Edinburgh.

SPONTANEOUS PROLAPSE OF UMBILICAL CORD DURING EARLY MONTHS OF PREGNANCY

Spontaneous prolapse of the umbilical cord during the early months of pregnancy appears to be of sufficiently rare occurrence to justify a brief description of the following case.

Mrs. S., aged 37, engaged me to attend her at her confinement. She had had three children, the eldest being 16, and all previous confinements were normal. The patient had been under my care for about a month, receiving a course of intensive alkali treatment for gastric ulcer, and it was during the convalescent stages of this complaint that I made the routine ante-natal examination. All pelvic measurements were normal, and the uterus corresponded in size to a pregnancy of five months' duration. Foetal heart sounds could be heard quite distinctly, and, apart from a very slight degree of uterine prolapse, there were no abnormalities worthy of record.

A few days later I received a message from the patient requesting me to visit her immediately as "her inside had come down." Upon my arrival she explained that during the early hours of the morning she had discovered something protruding from the vagina, but had not experienced any symptoms suggestive of labour pains or abdominal discomfort of any description. There was a loop of normal pulsating cord, measuring about eight inches, protuding from the vagina, but apart from this the cervix would only admit the tip of the index finger. There were no uterine contractions.

It was evident that the only line of treatment to be adopted in this case was to encourage the early onset of labour. This was accomplished by the administration of continuous hot rectal saline, and pituitrin in 2.5 unit doses when pains threatened. Labour commenced about eighteen hours after the prolapse of the cord, and the subsequent history of the case was uneventful; the foetus and placenta were entirely free from abnormalities.

Tollesbury, Maldon.

Reports of Societies

OBSESSIONAL NEUROSIS

At the meeting of the Medical Society of Individual Psychology on May 14th, with the president, Dr. O. H. WOODCOCK in the chair, Dr. M. C. LUFF read a paper on a case of obsessional neurosis.

After a brief summary of the chief features of interest presented by the case, Dr. Luff considered these and other points in more detail. The patient was a married woman, aged 30. The obsessions of which she complained showed a close relation to schizophrenia. This finding suggested that in this case there was no clear demarcation between psychoneurosis and psychosis—a possibility which further study of the case served to confirm. Thus neither the fears from which she had suffered from the age of 7, nor

similar symptoms which arose in the course of treatment, could be clearly differentiated from delusions. The same lack of true insight was displayed in the way in which she associated herself with crimes read of in newspapers. Her style of life illustrated in many ways Adler's views as to the mechanisms which might underlie neurotic symptom formation. A pampered only child, she was ill adapted to meet any rebuff to her wish for complete domination. Her hostility to her father was largely connected with the fact that he teased her. Attempts to educate her away from home had to be abandoned because she was so unhappy at school, feeling that the girls did not like her. Ill adjusted to the demands of society, she was equally so with regard to sex. With romantic fantasies of the ideal husband, she married a man whom she despised. She came for treatment two years after marriage, and normal sexual relations were established only as a result of psychotherapy.

THE PSYCHOLOGICAL FACTOR IN THE RHEUMATIC SYNDROME

Dr. M. B. RAY read a paper on the psychological factor in the rheumatic syndrome. He prefaced his remarks by a survey of the predisposing and exciting causes of rheumatism. From this point he passed on to matters of a more general nature. He defined environment as that "which embraces everything that interacts in any way with the individual, be it a group of cells or the whole." He considered that it was the quality of this interaction which determined good or bad function. As an example, he pointed out that it was because the autonomic and endocrine systems helped to maintain such a dynamic equilibrium that they were essential to health. Certain observations indicated that rheumatoid arthritis might be related to a permanent autonomic imbalance. The possibility that this finding might be in part dependent upon psychological factors was suggested by the well-known clinical fact that mental states might exert a profound effect upon the autonomic endocrine balance, and vice versa. He had found clinical confirmation for this *a priori* assumption in his work at the clinic of the British Red Cross Society. He could recall several cases of hydrarthrosis which had been due to sudden mental shock. Rheumatoid arthritis was most common in women. Brachial neuritis and sciatic neuralgia attacked more particularly worrying, anxious people. He concluded with a summary of several case histories in which the rheumatic condition seemed to have been psychologically determined.

INTRACRANIAL COMPLICATIONS OF EAR DISEASE

At the last meeting of the Section of Laryngology and Otology of the Royal Academy of Medicine in Ireland, with the president, Sir ROBERT WOODS, in the chair, Dr. HORACE LAW read notes on two cases of aural disease with intracranial complications.

The first was a case of lateral thrombosis with fatal termination due to lung abscess. The patient, a girl of 18, was brought to hospital on August 4th, 1930, suffering from pain in the right ear together with high fever. The history was that for a fortnight these conditions had existed, accompanied by tenderness and a grave amount of constitutional disturbance. On examination, there was tenderness and some swelling behind and above the right ear; an acute inflammation of the drum was found, with a copious discharge. There was no swelling over the mastoid or in the tissues of the neck. The internal jugular vein could not be palpated, and there was no sense of discomfort on deep pressure in the neck. An ordinary radical mastoid operation was done, a large periosteal abscess being found, with cholesteomatous debris in the antrum and middle ear. There was no indication to proceed further, as enough had been found to account for the high temperature and pain. Three days later, however, the patient had two rigors. The lateral sinus over a large area was at once laid bare, and a perisinutic abscess revealed; the sinus was soft, and showed no signs of thrombosis; the condition of the neck was exactly as mentioned above. Unfortunately this procedure seemed to make no difference to the condition of the patient, who still ran an extremely high temperature, going up most nights to 104° F. Injections of S.U.P. 36 and scarlatina antitoxin were tried, but had no influence on the course of the trouble. Eleven days after this operation the patient again had another rigor, and her condition was so serious that Dr. Law decided to cut down on the jugular vein. He opened the sinus above, which bled freely. The jugular vein was not easy to locate, as the tissues were extremely disintegrated, and the vein itself very soft. It was found to be full of pus as far down as the root of the neck. The wound was plugged and left open. A probe was passed up to meet another in the jugular bulb; this portion was proved to be patent. The local condition steadily improved, but the patient developed definite lung symptoms and began to expectorate evil-smelling sputum. Haemorrhages supervened, one of which proved fatal on September 6th.

The second patient was a female, aged 17, who was brought into hospital on November 21st, 1930, in an unconscious condition. The history was that she had acute otitis some days previously, growing rapidly worse and becoming unconscious on the morning of the 21st. Beyond the discharge from the ear it was not possible to make any definite diagnosis. Dr. Bewley saw the patient and found the reflexes fairly normal; there were no gross eye signs. He made a lumbar puncture and withdrew 50 c.cm. of fluid, under pressure, but quite clear. Dr. Law at once did a radical mastoid, laying bare the sinus and breaking down the tegmen tympani. In the groove of the sinus and under the tegmen were found fairly large subdural abscesses. When that of the tegmen was opened, the patient at once stopped breathing, though the heart remained strong and the pulse regular. She was kept alive partly by artificial respiration and partly by intratracheal oxygen, and the rest of the operation was completed as mentioned above, leaving the area wide open. The following remedies were used in an effort to make her breathe: oxygen, carbon dioxide, stimulants, strychnine 1/10 grain, pituitrin, sterile saline intrathecally. These various attempts were continued for four hours, the pulse remaining good throughout; after that time, as there seemed to be no prospect of any natural respiration, the attempts were given up.

Dr. T. G. WILSON, referring to the second case, said that when respiration ceased in these circumstances a cerebellar abscess was usually present, and its evacuation was usually followed by restoration of respiration. Dr. GEOFFREY BEWLEY said that he had performed the lumbar puncture, and that he did not think the cessation of respiration was due to this procedure, notwithstanding the large amount of fluid drawn away. He thought some more serious intracranial trouble was present. Mr. A. A. MCCONNELL suggested three methods of restoring respiration which had proved successful in cases of cerebellar tumour. These were: (*a*) changing the position of the head, from flexion to extension, or vice versa; (*b*) putting the patient into the Trendelenburg position; and (*c*) opening the foramen magnum.

Dr. LAW, in replying, said that permission for a post-mortem examination had been refused.

Others who contributed to the meeting were Dr. P. J. KEOGH, who showed a case of papilloma of the right vocal cord; Dr. R. R. WOODS, who read notes on a condition he described as vallecular dysphagia, and on a case of abscess of the temporal lobe; Dr. P. DEMPSEY, who showed a case of epithelioma of the fauces successfully treated by diathermy; Dr. T. O. GRAHAM, who demonstrated two successful results of the operation for lateral sinus thrombosis; and Dr. T. G. WILSON, who read notes on a case of temporal lobe abscess in a child of 9 months, and on a case of perisinus abscess with purulent meningitis.

Reviews

FORENSIC MEDICINE

Two textbooks on forensic medicine from American sources have recently appeared. One of these, written by ELMER D. BROTHERS[1] of the Chicago Bar, deals almost entirely with the legal aspect of the subject, and gives a clear exposition of the law as it affects the medical practitioner. Although the outlook is essentially American there is much to interest English readers. The author clearly defines the contractual relations existing between the physician and his patient; he goes into the question of civil and criminal malpractices and the legal liabilities that may arise out of the negligence of nurse, assistant, or partner. In discussing the question of torts, he raises a point which appears amusing to us over here—namely, the question of false advertisement and fraud by physicians. He cites decisions where patients have sued practitioners for fraudulently guaranteeing to cure certain diseases known to be incurable. In one instance a person was positively assured that he could be cured, and on this assertion he gave a written agreement to pay 500 dollars. He was suffering from the effects of a fractured base, and when he found that no cure was possible he successfully sued the doctor and institution for fraudulently obtaining his money. The manner in which such cases of "infamous conduct" are dealt with, if they are subject to the control of any professional body, is not disclosed by the author. The section containing miscellaneous legal information is of much interest. Mr. Brothers devotes about fifty pages to the medical aspect of his subject, and the least said about this section the better. There are many mistakes, and the author would be well advised either to omit this part altogether or have it revised by a medical specialist. The book is, in general, good reading, and if the author is weak on the medical side he certainly gives us some very interesting material from the legal side. While not of great value to the medical practitioner, and even of less to the medical student, it has its place on the library shelves of universities and institutions.

The second book[2] is from the pen of Dr. RALPH WEBSTER, professor of medical jurisprudence in Chicago University, and co-author of the well-known textbook by Petersen, Haines, and Webster. We should not have expected any dearth of material for the medical jurist practising in Chicago, and were the more surprised to find an almost complete lack of original matter. In fact, the constant references for details to other sources, particularly to Petersen, Haines, and Webster, suggests that it might be better to read the original in the first place. The book lacks proportion, undue prominence being given to certain sections at the expense of others equally important. Thus, toxicology accounts for about 500 out of the 800 odd pages in the book, and though the author says that "wounds involve the medical practitioner in court proceedings more frequently than any other cause," he devotes only thirty pages to this important part of legal medicine. On the other hand, twenty-three pages are given to ethyl and methyl alcohol; a fact not without significance when we consider that the author is dealing with a prohibition country. The technique for the examination of blood-stains is well described, and the chapters on various forms of violent death, infanticide, rape, etc., follow conventional lines. There is in general, however, a lack of practical detail, which greatly detracts from the value of the book. For example, there is no instruction in the method of performing a post-mortem examination, and exhumation is not even mentioned; there is no description of wounds in various parts of the body, and even such things as fractures of the skull, cerebral haemorrhage, concussion, compression, etc., are not mentioned. No information is given about the identification of firearms and projectiles, or on the examination of powder residues, although firearm injuries would appear to be of considerable importance in the United States in general, and in Chicago in particular. The toxicological section is easily the best part of the book, indicating clearly that the interests of the author are chemical and analytical rather than clinical and pathological. The action of poisons and their isolation and detection are discussed in a practical manner, as by one quite at home in this branch of work. The precautions in connexion with the prescribing, dispensing, and sale of poisons, however, are not mentioned, although the Harrison Law and the Volstead Act, with references to narcotic and alcoholic substances, are discussed in the earlier pages. In the general sections of the book we find much material which is both interesting and instructive, and which gives a basis for comparison of our own methods and statutes with those of the United States. For example, there has been for some time in this country a growing feeling of dissatisfaction with the coroner system, and it is with interest that we note the rapid replacement of coroners in America by medical examiners, whose duty it is, when called upon, to investigate the medical facts in all cases where the cause of death is unknown. The author adds his quota of praise for the new system. The book is well printed and bound, but would be much improved by the introduction of more illustrations; the illustrations given are not original, and do not cover the range of the subject-matter sufficiently. With such gaps in it, the book can hardly be recommended to the student or to the general practitioner, but will be of interest to the specialist in forensic medicine.

STREPTOCOCCI AND SCARLET FEVER

The view that a streptococcus is the specific cause of scarlet fever is now generally, although not universally, accepted. The grounds on which this conclusion is based are discussed in great detail in the elaborate work of Drs. DAVID and ROBERT THOMSON on "The Rôle of the Streptococci in Scarlet Fever," which forms the sixth volume of the *Annals of the Pickett-Thomson Research Laboratory*.[3] As is well known, a streptococcus is to be found in the throat in almost every case of scarlet fever, and it has been proved experimentally in human volunteers that the disease may be produced by swabbing the throat with pure cultures of the organism. It has also been contracted in the laboratory by persons working with the streptococcus. In 1924 Dick and Dick made the important discovery that this streptococcus produces an exotoxin, demonstrable in Berkefeld filtrates, which, when injected into susceptible persons, is capable of producing the general malaise, nausea, vomiting, fever, and rash which characterize the spontaneous disease. The same observers have also shown that the filtrate may be used, by intradermal injection, as a test of the susceptibility and non-susceptibility to the disease; for example, of 20,856 persons whom the Dick test indicated as non-susceptible, none contracted the disease after passing through one or more epidemics. It has been further shown that the immunization of susceptible persons may

[3] *Annals of the Pickett-Thomson Research Laboratory*. Vol. vi: The Pathogenic Streptococci: The Rôle of the Streptococci in Scarlet Fever. London: Baillière, Tindall and Cox; Baltimore: The Williams and Wilkins Company. 1930. (Pp. xiii + 470; 13 plates. £2 2s. net.)

be effected by injections of the toxin or of antistreptococcic horse serum, and also by vaccination.

The evidence in support of the streptococcal origin of scarlet fever is therefore very strong; and the modern view of its pathogenesis suggests an analogy with that of diphtheria—namely, that the disease is a local infection of the throat and cervical glands, while the general symptoms are the result of the circulation of a soluble exotoxin. Some have thought that the presence of streptococci in the scales is evidence of the transmission of the organism through the blood, but Deicher has found that patients who have been bathed and are still desquamating show no streptococci in the scales. Apart from the propagation of the disease through contaminated articles, such as milk, the authors consider that the chief mode of spread is by droplet infection from the respiratory tract, especially of human carriers such as discharged convalescents and missed or mild cases without the typical rash. The frequency of this mode of propagation is sufficient to explain the inefficiency of such measures as isolation, disinfection, and fumigation, in controlling the disease. The highly technical question of the precise relation of the streptococcus to other haemolytic streptococci appears to be still *sub judice*; the authors incline to regard it as a distinct species.

The authors deserve high praise for the accomplishment of what, without exaggeration, may be called their stupendous work. They have apparently brought together the entire extant information on the subject in a form which seems to render a reference to work of earlier date superfluous. An inspection of the copious index to the volume will give some idea of the immense amount of detail included in the review, which has entailed an analysis of some 1,400 publications. The monograph is the eleventh of a series on the pathogenic streptococci, the earlier fasciculi of which were referred to in the *Journal* of August 3rd, 1929 (p. 206). The streptococci of erysipelas and skin diseases will form the subject of a volume which is due to appear in the present year.

THE VISCEROGRAPHIC METHOD

The introduction of the graphic method in the investigation of the physiology and pathology of the circulation was so fruitful of results that it is surprising that it was not immediately adopted in the study of other contractile organs. The first attempt at the systematic employment of the method in the latter was undertaken by Professor DANIELOPOLU in 1921, although isolated observations had been made before that date by Morat, Coulson, and Cannon. Professor Danielopolu has since been engaged in an extensive research, a detailed account of which is contained in his work on the Viscerographic Method.[4] The apparatus employed is simple, consisting of a hollow sound with a bladder tied to its extremity; this is introduced into the organ, and the bladder, by a suitable mechanism, is distended to the desired degree of tension. The variations of tension produced by the contractions of the organ are registered in the usual way in the form of a curve on a revolving drum with smoked paper. The method has the advantages of being exact and giving measureable results, and of being directly applicable to the human subject, as a clinical procedure. By its means the physiology, pathology, and the normal and pathological pharmacology of the motility of the contractile viscera have been studied in connexion with the oesophagus, stomach, intestines, and bladder, with results which leave no doubt of the value of the method.

Professor Danielopolu has in the first place described the normal curve of motility for the organs mentioned, in connexion with which he has some interesting facts to record relating to the reflex mechanism concerned. He next describes the oculo-visceral reflexes, the influence of sleep on motility, and the action of hyperventilation of the lungs. The pathological conditions studied include tetany, stenosis and spasm of the oesophagus, and pyloric stenosis; the pharmacological section deals with the action of atropine, adrenaline, calcium salts, eserine, pilocarpine, papaverine, insulin, ephedrine, and tobacco. In the course of his investigations the author was able to explain certain discrepancies which have been thought to exist between the action of the vegetative nervous system on the circulatory apparatus, and its apparent action on other hollow viscera. The more exact results obtainable by the viscerographic method have shown that the same rules hold good in the alimentary tract and bladder as in the circulatory system. The book is illustrated with a large number of viscerograms, which render the author's descriptions easy to follow.

PROTOZOOLOGY

The study of the unicellular animals has made considerable advances in the past twenty years, and the protozoan parasites are now regarded as one of the most important factors in the development of tropical countries. This has stimulated general interest in the group as a whole, and many universities and colleges now offer courses dealing with both free-living and parasitic protozoa. It is to meet the need of such classes that a *Handbook of Protozoology*,[5] by R. R. KUDO, has been published. Most modern publications on the subject emphasize the parasitic forms, and do not give much space to the taxonomy, biology, and orientation of the free-living forms from which the parasitic group has been evolved. The present work therefore provides a handbook of introductory information on the common and representative genera of all the groups of protozoa. It is divided into two parts: an introductory section of three chapters giving a general account of the morphology, physiology, and reproduction of the protozoa, and a larger second part which deals with the taxonomy, biology, and development of common forms. Each chapter concludes with a list of important references, which serve as guides for more intensive study. The book is lavishly illustrated with line drawings, mostly under a comparatively low magnification, so that they can be of the greatest practical value to students using the ordinary powers of the microscope. There is, finally, an appendix on collection, cultivation, and observation, and an adequate subject and author index.

The book is an excellent one, within the limits set by its author, and will be of considerable value as a textbook to all interested in a general account of the phylum.

NOTES ON BOOKS

A second edition of *A Text-Book of Medicine*,[6] by American authors, has recently made its appearance under the editorship of Dr. RUSSELL L. CECIL, with whom is associated Dr. FOSTER KENNEDY in the section devoted to diseases of the nervous system. It is little more than two years since a review of the book appeared in these columns, so that it is only necessary to say that the whole work has been thoroughly revised and reset. Since the first edition was published death has claimed five of the contributors, including that eminent Japanese Dr. Hideyo Noguchi, who wrote the chapter on yellow fever. The places of these men have been taken by others

[5] *Handbook of Protozoology.* By Richard R. Kudo, D.Sc. London: Baillière, Tindall and Cox. 1931. (Pp. x + 454; 175 figures. 25s. net.)

[6] *A Text-Book of Medicine*, by American Authors. Edited by Russell L. Cecil, M.D., Sc.D.; Associate Editor for Diseases of the Nervous System, Foster Kennedy, M.D., F.R.S.E. Second edition. Philadelphia and London: W. B. Saunders Company. 1930. (Pp. xxv + 1592; 90 figures. 40s. net.)

equally distinguished in the special subjects with which they deal. Several new articles have been added, and the work has been brought thoroughly up to date. It can be recommended as a safe guide for all—students and practitioners alike.

Volume xi (Metabolic Diseases) of "Medical Practice"[7] will prove a useful addition to the preceding volumes. It aims at being comprehensive, and has succeeded. There can be few conditions classifiable as disorders of metabolism which do not receive mention. Its length, however, is only 118 pages (excluding the bibliography and index), and, as would be expected, the treatment accorded to each disease is but brief. The author has endeavoured, not without success, to bring out the salient points about each condition. The amount of space devoted to treatment is perhaps, in most cases, shorter than is altogether advisable.

The Diet Book,[8] by Mrs. MARGUERITE REQUA REA, will prove a compact and useful guide to medical men who are concerned with the practical and culinary details of dietary—and most medical men are, from time to time, so concerned. It should also be of service to the housewife in carrying out the doctor's directions.

The eighth volume of *Allen's Commercial Organic Analysis*[9] deals with glucosides and with the vegetable bitter principles which are not glucosidal. It also includes an account of enzymes, animal bases and acids, cyanogen compounds, proteins, and the digestion products of proteins. These volumes afford ready access to the kind of information which would otherwise be obtainable only from original publications. Organic analysis is peculiarly dependent for success in its general practice on information which is wanted only at rare intervals. The purpose of the work would be partly fulfilled if the book did no more than provide this information in assorted form; but it does much more. Great care and much labour have been bestowed on the arrangement and co-ordination of the subject-matter for the purpose of saving the reader's time and effort. Thus for the glucosides, a diverse class of substances difficult to classify, a table of some 140 varieties is given, showing the source of the substance, its chemical formula, melting point, specific rotation, and the products resulting from its hydrolytic cleavage. The other chief essential in a book of this character is also well provided for—namely, technical directions for the laboratory worker, which vary much in different circumstances. Under hydrocyanic acid, for example, special attention is given to methods of recognition and determination of the substance in cases of poisoning.

In his *Selected Readings in the History of Physiology*[10] Dr. J. F. FULTON, who, after several years' residence at Oxford as Fellow of Magdalen College, was recently appointed Sterling Professor of Physiology at Yale University, has collected a number of passages illustrating various branches of physiology from Aristotle down to F. G. Banting. The work is divided into eight chapters, dealing respectively with general principles, the circulation of the blood, the capillaries, respiration, digestion, muscle and peripheral nerves, the central nervous system, and miscellaneous subjects. The selection from each writer is prefaced by a short account of the man and his work, and the text is freely interspersed with portraits, facsimiles of title-pages, and other illustrations from the works of the older physiologists. Dr. Fulton is to be congratulated on his selection of the extracts, many of which are from works not readily accessible, as well as on his translation of foreign writers and his judicious comments. The work should appeal not only to the medical graduate interested in the history of medicine, but also to the medical student, who, as Dr. Fulton remarks in his preface, will realize from its perusal that men as young as himself have made important contributions to physiology.

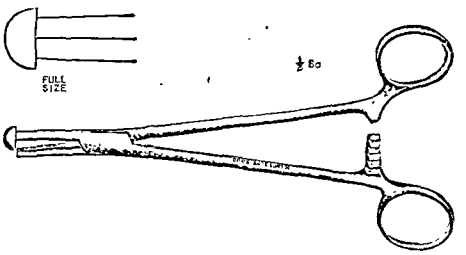
PREPARATIONS AND APPLIANCES

PHRENIC EVULSION FORCEPS

Mr. WALTER MERCER, F.R.C.S.Ed. (Edinburgh), writes:

In performing the operation of phrenic evulsion the phrenic nerve is exposed in the neck under a local anaesthetic and grasped by fairly strong forceps. The nerve is then divided above the forceps, and pulled slowly out from the chest cavity. The evulsion has to be very slowly proceeded with, so that the nerve will be removed in as great a length as possible. If it is pulled out too strongly or too quickly the nerve may break. If this breakage occurs above the communicating branches which reach it below the clavicle, the diaphragm will still receive nerve impulses from these branches, so that the operation will be useless.



By experience one finds that the best way of controlling this gradual pull on the nerve is to rotate the forceps and wind the nerve on to them very slowly. If ordinary forceps are used the nerve slips off the end, since the forceps cannot be kept on the same plane as the nerve, which lies at the bottom of the fairly deep wound. To overcome this minor difficulty these forceps were produced. The round tip projects from the edges of the blade, and so prevents the nerve from slipping over it. The blades themselves have longitudinal grooves, assuring a good grip of the nerve. The forceps should be of a fairly heavy type, as this ensures a firmer and more complete control of the amount of force required.

The forceps are made by Down Bros. Ltd., London.

"BAROLAC": BARIUM SULPHATE IN SUSPENSION

We have received from Burroughs Wellcome and Co. a sample of their brand of barium sulphate for *x*-ray purposes, made up in the form of 30 per cent. suspension. The appearance of the liquid is of milky whiteness; it is quite odourless, and neutral to the taste, as well as of satisfactory bulk, and the manufacturers give an assurance that it is entirely free from soluble barium salts. The suspension is very smooth, and the salt is in so finely divided a condition that no mucilaginous agent like tragacanth is necessary for effective distribution of the particles. The absence of anything disagreeable from the meal makes flavouring agents unnecessary, but vanilla, saccharin, or cocoa can be added if desired. The name of "barolac" has been given to this preparation, which is issued in Winchester quarts.

OVARIAN HORMONE

Theelin is a solution of the active crystalline ovarian hormone prepared by Messrs. Parke, Davis and Co. The crystalline substance is stated to have an activity of 3 million rat units per gram. The solution contains 50 rat units per c.cm., and is recommended for use subcutaneously in doses of 1 to 2 c.cm. daily.

Intensive investigation is at present proceeding on the therapeutic use of the follicular hormone. The isolation of the pure active principle is a great advance, but the dosage required to produce a therapeutic action in a woman is still very uncertain. There appears to be a general agreement that the use of this hormone is more likely to be attended with success in cases of secondary amenorrhoea than in cases of primary amenorrhoea.

ISCHAEMIA OF MUSCLE AS A CAUSE OF ANGINAL PAIN

ST. CYRES LECTURE BY SIR THOMAS LEWIS

Sir THOMAS LEWIS delivered the St. Cyres Lecture at the National Hospital for Diseases of the Heart on May 14th, with Dr. FREDERICK PRICE in the chair. The subject of the lecture, of which the following is an abstract, was ischaemia of muscle as a cause of anginal pain.

The lecturer said that when he referred to angina pectoris he would follow Heberden in employing this term as the name of a specific disease. He did not intend to touch on the general pathology of angina pectoris, but only on the origin of the pain, which was one of its leading symptoms. The cause of this pain had been the subject of much theoretical debate since Heberden gave the first classical description of the disease. In those early days it was discussed by the Gloucestershire Medical Society, of which Edward Jenner was a member, and it was Jenner who first considered that angina pectoris was a disease arising from an affection of the coronary arteries. In a letter he wrote to Heberden he stated that it was the function of these arteries which was affected. Later Parry put plainly the case for arterial disease. He recognized that the rigidity of arterio-sclerotic coronary arteries impeded the blood flow to the cardiac muscle, and that though sufficient blood might pass to nourish the muscle when the patient was at rest, the quantity might be inadequate during vigorous activity. He believed, therefore, that under unusual exertion the power of the heart failed, and that paroxysms of syncope anginosa arose in consequence. While this was an explanation of angina pectoris, it did not account for anginal pain. Parry's book on syncope anginosa was one of his best-known works, but he was even better remembered for the term "syncope anginosa" itself; he considered that many cases of angina pectoris were associated with syncope, but subsequent experience had shown that he was wrong. Syncope was rare in anginal attacks.

In 1809 Allan Burns drew an analogy between the heart in angina pectoris and the deficient nourishment of a limb "begirt by a ligature." The heart, like the limb, was working under conditions in which the flow of blood was impeded. Burns made no mention of pain induced in the limb, and it was probable that he almost entirely followed Parry in his view of the disease. Benjamin Brodie, in 1846, referred to cases of arterial disease in the leg with gangrene of the toes, and compared them with angina, but he, too, made no mention of pain. It was left to Potter, in 1866, to draw a comparison between intermittent claudication in a limb and the pain of angina pectoris.

ARTERIAL OCCLUSION

Sir Thomas Lewis then went on to say that experiments had been made to decide where the pain arose in a limb in which the arterial flow had been temporarily occluded. The view had been held by Zach and others that it originated in the arteries, and was due to spasmodic contraction of their walls. He and his colleagues had set this explanation on one side because they had found that if the blood supply to the forearm was occluded and the muscles then exercised until the pain became severe, the removal of the ligature gave rise to an immediate flushing of the muscles, synchronous with the first pulse beat; the pain, however, persisted for some seconds after the removal of the ligature. Potter, in his study of intermittent claudication, had evidence of the condition as found in horses. Charcot observed a patient who developed cramp-like pain on walking, and ascribed the pain to cramp comparable to cadaveric rigidity. The conception of the pain as due to cramp, however, was not correct, since the pain could be induced easily by exercising a ligatured limb, cramp being rare. The subject might complain of cramp-like pain, but no increase in the tone of the muscles could be observed.

The method used by the lecturer and his co-workers for engendering the pain was simple. A small instrument with a spring registering the strength of the movement was taken in the hand and gripped at intervals of one second, as recorded by a metronome, the circulation being cut off by means of a sphygmomanometer. The pain arose quite regularly at the end of thirty to thirty-five seconds; it grew steadily in intensity until, after from seventy-two to seventy-eight seconds, it became so intolerable that the subject stopped. There was no question of one person stopping at fifty seconds and another at ninety; the time was in the region of seventy-two to seventy-eight seconds for different subjects and for the same subject on different days. It was possible, therefore, to make experiments with a basis of uniformity.

The character of the pain was difficult to describe. It could be said to be diffuse, and even aching. It was situated in the neighbourhood of the acting muscles, and could be produced in any group by bringing them into play. Moreover, the muscles became tender, and this tenderness persisted after the pain had disappeared.

MUSCULAR ANOXAEMIA

Another theory of the causation of the pain attributed it to lack of oxygen in the muscle. The unsoundness of this idea could be demonstrated by two simple experiments. In the first place, if the circulation to a limb was stopped but the limb kept at rest, no pain would develop, even when the limb became anaesthetic after twenty or thirty minutes. Secondly, if in a limb in which the circulation was occluded the subject worked his muscles until he knew that he was within two or three contractions of the development of pain and then stopped, no pain would develop; the muscles had been working vigorously and would still be using up oxygen after they were at rest, and yet the pain did not appear.

On the other hand, it would be observed that whether the load on the muscle was increased or the rate of the contractions augmented, both the onset of pain and the point at which it became intolerable would be expedited. Therefore the onset was determined by the amount of energy expended by the muscle. Sir Thomas said that he and his colleagues had found that certain simple observations had given them the clue to the origin of the pain. If the circulation was cut off and the limb worked until the pain reached a certain intensity, either mild or severe, and then allowed to rest, as long as the ligatures remained in place the pain would persist at the same degree of intensity, without any signs of abating. As soon as the ligature was released the pain disappeared in from two to four seconds. He believed, therefore, that the cause of the pain was chemical or physico-chemical in origin. The theory they had reached was that changes occurred in the muscle as a result of muscular work, and that these gave rise to a change in conditions in the tissue spaces, outside the muscle fibres, and that this change was responsible for the pain. Their reason for considering that changes in the tissue spaces, and not in the muscle fibres themselves, produced the pain depended on another series of experiments.

ALTERATIONS IN THE TISSUE SPACES

When the ligature was released the pain went almost in a flash, but if as soon as it had disappeared the ligature was restored and exercise resumed, the onset of the pain was earlier than usual, and the shorter the period of rest the more quickly it arose. Actually the muscle did not

recover completely for at least ten minutes after the removal of the ligature, and it might be assumed that the process engendered in the muscle fibres required a longer period to subside than the process in the tissue spaces. Again, if exercise was begun before the ligature was applied and then carried on after the circulation had been occluded, the pain developed more quickly than usual. There could have been no heaping up of the factor responsible for pain in the tissue spaces before the application of the ligature, but there must have been an accumulation in the muscle fibres of the factor produced there by exercise.

If, with the circulation occluded, exercise was performed until pain arose, and if the ligature was then released but the exercise continued until the pain disappeared, the re-application of the ligature and the simultaneous cessation of exercise would result in the return of pain in twenty to thirty seconds. Some change in the condition of the muscle must therefore be ultimately responsible for the pain. *Pari passu* with the process developing in the muscles of an exercised limb in which the circulation was occluded, there occurred the collection in the tissue spaces of the factor responsible for pain. If the circulation was not occluded the tissue spaces would be kept free of this physico-chemical factor, whatever it might be, and pain would not arise. In passing to a consideration of pain in angina pectoris it might be said that, if this was due to ischaemia, pain ought to arise either when the work of the muscle remained constant and the blood supply was decreased, or when the work of the muscle was increased and the blood supply failed to keep pace. In coronary thrombosis, although there was no increase in the work of the heart, the vessels were failing to supply the usual quantity of blood. There were certain similarities and differences between the pain due to coronary occlusion and the pain of angina pectoris; in both the pain was severe and continuous and not spasmodic, like, for example, bowel pain. It was often intense, and the situation was the same in both: the pain was felt over the upper and lower sternal regions and over the precordium, and the spread was the same in both cases. The two conditions differed in the predominance of epigastric pain in coronary thrombosis, and the greater length of the period during which the pain was felt.

MUSCULAR ISCHAEMIA

Coronary thrombosis offered the best possible evidence that pain actually did arise from coronary occlusion. Sutton had experimented by placing a ligature round the coronary arteries of dogs, under general anaesthesia. On the recovery of consciousness, traction on the ligatures produced immediate and definite symptoms of pain in the dogs; the clinical evidence, however, should take precedence of this, since a ligature round an artery was bound to affect surrounding structures. Sutton was unable to produce pain by experiments on other structures in the neighbourhood of the coronary arteries, and on this point his observations went further than clinical evidence.

If coronary thrombosis was thought of in terms of muscular ischaemia, it could be assumed that the affected vessel was closed and that the muscle supplied by that vessel, continuing to work, heaped up the pain-producing factor in the tissue spaces; the pain began mildly and grew more intense, but the heart muscle, unlike the muscle of a limb, was driven inevitably to continue its contractions. For this reason the pain of coronary thrombosis must persist for a long time.

Parry's theory of pain in angina pectoris postulated an increase of strain in a sore or irritable aorta; if this were the case a rise of blood pressure alone should be sufficient to initiate an attack. But it had been observed in certain cases of paroxysmal tachycardia, in which there was no rise of blood pressure, that attacks of anginal pain might occur during the paroxysm; in these cases there could be no question of strain on the aorta. One observer of attacks of angina pectoris occurring in himself recorded that when he was in company he had often been able to conceal the pain and to go on moving during the attack until the pain stopped. Was the pressure diminished in these circumstances, or did the arteries accommodate themselves to the attack? Far more observations on the blood pressure during attacks required to be made before a definite statement could be offered.

In the angina of effort it must not be assumed that the pain was due to a rise of blood pressure unless this could be verified. Muscular ischaemia supplied an adequate explanation of this type of angina pectoris, as of other types. In angina pectoris occurring in males with grave heart disease, usually aortic regurgitation, the attacks were associated in the early stages with effort, but in the later stages they occurred while the patient was in bed, usually in the small hours of the morning. The attacks were associated with throbbing in the chest, head, and neck, and the rise in blood pressure and pulse rate was conspicuous; amyl nitrite was particularly effective in relieving these patients. But the blood pressure was not the only factor in producing pain, as could be shown by quoting the case of a man in whom the attacks developed following food.

At a time when his systolic pressure was 142 and his pulse rate was 77 he was given a piece of toast. By the time he had finished it his blood pressure was 152 and his pulse 112. Within a few moments an attack began, his blood pressure being 172 and his pulse rate 116. On another day the same man was made to perform exercise standing up; his blood pressure rose from 167 to 205, and his pulse rate from 78 to 108, but no pain developed. The experiments were repeated on another day with the same results; food produced pain, and exercise had no such effect. The blood pressure at the end of the attack initiated by food was 179, and the pulse rate 108.

AMYL NITRITE AND BLOOD PRESSURE

The general belief was that amyl nitrite relieved an attack of angina pectoris by lowering the blood pressure and decreasing the work of the heart; this was the view of Brunton, who introduced it. Few observations of the action of the drug on the blood pressure during an attack had been made to confirm this theory, and Sir Thomas Lewis's own continuous observations in the ward had shown it not to be the full story. In one case the blood pressure was 200 and the pulse rate 144 during an attack; one minute later, after an inhalation of amyl nitrite, the pain was gone, the blood pressure was 212, and the pulse rate 132. Other cases in his series had shown comparable results; in all of them the differences in the blood pressure were very small, and where a fall occurred it was not great enough to bear out the theory that amyl nitrite acted by reducing the blood pressure. It seemed far more likely that it acted by causing a dilatation of the coronary vessels. In coronary thrombosis inhalation of amyl nitrite gave no relief because it could not open up the blocked vessel, but in those cases where it relieved the pain experience showed that it did not have any marked effect upon the blood pressure. Inhalation was followed only by a transient flushing of the skin, and yet an attack might be warded off by its use. The likelihood was that it dilated the coronary arteries, and the increased supply of blood swept out the pain-producing factor from the tissue spaces.

In conclusion, Sir Thomas Lewis said that he had attempted in this lecture to outline the main facts in support of the view that ischaemia of the muscle was the cause of anginal pain.

British Medical Journal

SATURDAY, MAY 30th, 1931

ETIOLOGY OF DISSEMINATED SCLEROSIS

Early last year Miss Kathleen Chevassut,[1] working at the Westminster Hospital, reported the recovery from the spinal fluid in cases of disseminated sclerosis of an organism or virus, which was only discernible by Barnard's ultra-microscopical technique. She named it *Spherula insularis*, and credited it with etiological significance. She emphasized the importance of inoculating culture tubes with the fluid immediately after its withdrawal, and described certain subsequent changes in the *p*H of the media employed, which, if other causes such as ferments or enzymes could be excluded, might support the view that a living entity was present. Sir James Purves-Stewart,[2] using a vaccine prepared from these cultures for intravenous injections, obtained promising clinical results, although it was admitted that in disseminated sclerosis, with its frequent remissions and subsequent exacerbations, caution was necessary in interpreting such clinical results as being due to the vaccine treatment. Confirmatory pathological discoveries were recorded later by Smith and Ransome.[3]

Commenting on Miss Chevassut's claims (*British Medical Journal*, June 14th, 1930, p. 1102) we indicated the necessity for repetition of the whole procedure under identical conditions by other workers, and expressed the hope that, in any event, her report would stimulate renewal of interest in the various problems of disseminated sclerosis, in this country and abroad. Two repetitions have been subsequently recorded. On January 8th of this year Dr. E. A. Carmichael[4] read a paper before the Section of Neurology of the Royal Society of Medicine, in which he gave details of an attempt to recover the *Spherula insularis*. He examined nineteen cases of disseminated sclerosis, but was unable to detect the spherules in the cerebro-spinal fluid in a single instance. He did not find the alteration in the medium employed for cultivation, but in the subsequent discussion doubt was expressed as to whether his technique was strictly comparable with that of Miss Chevassut. The latter point, alteration in the *p*H, is admittedly of secondary importance, since Miss Chevassut did not claim that this change was at present to be considered a proof of the existence of the *Spherula* as a living organism, but it has, undoubtedly, a bearing on the evaluation of the evidence as a whole.

In Paris, meanwhile, a parallel investigation was in progress, and Drs. Pierre Lépine and P. Mollaret[5] reported at a meeting of the Academy of Medicine on March 24th, 1931, that they had been quite unable to assure themselves that a specific virus had been discovered. In spite of taking the most rigid care to repeat exactly the work of Miss Chevassut they could not detect any difference between the cerebro-spinal fluids of patients suffering from disseminated sclerosis and those of other persons. They found in their controls the spherules and granules described by her, often in large numbers, but they never obtained, by cultivating them on similar media, the large colonies she had reported. The existence of filterable contaminants is admitted, and these two French workers are inclined to think that the bodies are of this derivation, and are not specific to disseminated sclerosis. Furthermore, they claim to have produced similar appearances by injecting a drop of human serum into the aqueous humour of the eye of a rabbit, and withdrawing and examining the fluid after twenty-four hours; they insist that the spherules then present were indistinguishable from those described by Miss Chevassut. They conclude that these bodies represent the results of flocculation of certain elements of human serum in special chemico-physical conditions, and have no definite pathological significance. Drs. Lépine and Mollaret investigated with equal care the changes in the *p*H of the media employed for cultivation, and report only a slight alkalinization attributable to the loss of carbon dioxide; they were unable to detect any evidence of the presence of a living and growing organism. On the other hand, they admit that "vaccines" have been prepared by them on the lines suggested by Miss Chevassut, and that they cannot so far exclude the possibility that there is some therapeutic benefit following the injection of such vaccines into patients as a form of non-specific protein therapy. They are therefore continuing to treat patients on these lines, and will report the clinical results when sufficient time has elapsed to make it clear whether or not the benefit is persistent and attributable to the vaccine. They are at present inclined strongly to the view that the *Spherula insularis* is a physical phenomenon only, brought about by the presence of human serum in the culture media into which the cerebro-spinal fluid was inoculated.

BOVINE TUBERCULOSIS IN MAN

The Ministry of Health has just issued a short pamphlet[6] designed to enable the general public to appreciate the significance of bovine tuberculosis to the community, and to understand the practical and scientific difficulties involved in its control both in man and in animals. It is now definitely accepted that man may suffer from tuberculosis originating from

[6] Reports on Public Health and Medical Subjects, No. [illegible]. Memorandum on Bovine Tuberculosis in its Relation to Man with Special Reference to Infection by Milk. Ministry of Health. H.M. Stationery Office. 1931. (6d. net.)

animals, the disease in each case being essentially the same in its general nature, though sometimes differing in degree. Children are particularly subject to infection with the bovine bacillus, and there is no doubt that a considerable amount of tuberculosis in childhood is caused by the drinking of milk from tuberculous cows. Assuming that the races of tubercle bacilli do not become modified by passage through man, and that the discovery of bacilli of the human or bovine type in any case of tuberculosis gives an accurate indication of the origin of the infection, it would seem that a large proportion of tuberculosis in children under 15 years of age—in some cases up to half—is caused by bacilli from cattle, with an annual death roll of about 1,000 in England and Wales. There is little or no evidence that pulmonary tuberculosis in children is caused by milk.

The disease is common in cattle, and while it is difficult to make an accurate estimate, there is reason to believe that it is not less than 40 per cent. Cows suffering from tubercular mastitis are the most important from the public health point of view, and between 0.3 and 6 per cent. appear to be so affected, with between 1 and 2 per cent. yielding tuberculous milk. There is no evidence to show whether the incidence of the disease in bovines is increasing or decreasing, though undoubtedly non-pulmonary human tuberculosis is definitely on the down grade. Complete eradication of all animals which react to the tuberculin test is impracticable in Britain, partly because of expense and dislocation of milk supply, and partly because it is doubtful whether the eradication would be permanent. At present we destroy all animals in an advanced state of the disease, but, even if this were completely carried out, it could not seriously affect the position either in man or in animals. Bang's method of building up tubercle-free herds by the segregation of calves at birth is somewhat costly, but is worthy of more extensive trial in this country than it has yet received. Preventive vaccination with B.C.G. vaccine has given promising results in calves, and there is evidence that a certain degree of immunity can be produced in these animals; but its protective value for children has yet to be established.

In Scotland the routine clinical examination of milk herds at frequent intervals by competent veterinarians, and the exclusion of diseased animals, has given most encouraging results. This method is being rapidly extended there, although it has only been tried to a small extent further south. Milk tests, both biological and microscopical, can give valuable assistance to this scheme; and the grading of milk, with its necessary good dairy hygiene, should constitute an important element in any comprehensive scheme for the improvement of the milk supply. Meanwhile, under careful methods of operation and scientific control, pasteurization can ensure a milk supply which is not only perfectly safe for consumption, but which retains its food value practically unimpaired by the heat to which it is subjected.

PATHOLOGICAL FUNCTION OF THE KIDNEYS IN RENAL DISEASE

Whatever may be said of the detailed accuracy of Cushny's theory of the secretion of urine there can be no doubt that it has acted as a fruitful stimulus to physiological investigations. When the facts of renal pathology are reviewed in the light of this theory some minor modifications seem to be necessary, such as those suggested by C. Holten and P. B. Rehberg,[1] who admit that there occurs in the glomeruli a filtration of fluid of the same composition as the plasma, but without the colloids. This filtrate is concentrated in the tubules by an active reabsorption of water, and by the back diffusion of the non-threshold substances controlled by the permeability of the cells of the tubules for the substance in question. These authors point out that creatinin is concentrated by the kidneys to a much greater extent than any other substance, and the diffusion back of creatinin through the tubules is practically *nil*. The amount of filtrate per unit of time can be calculated from a simultaneous determination of the creatinin concentration in plasma and urine, provided that the amount of urine per unit of time is known. For this reason the measurements of creatinin in the urine and plasma are likely to prove the most accurate means of determining renal function. We have in the Volhard-Strauss test of renal function a very useful indication of the activity of the kidney, particularly of the function of the tubules in the absorption of water. In this test the volume and specific gravity of the urine are determined in four consecutive hours after taking 1,000 c.cm. of water. The usual result is that most of it is excreted in the course of the four hours, and that the specific gravity falls to 1001–1004. In conjunction with this a concentration test is done in which, by putting the patient on a dry diet, the kidneys are induced to concentrate the urine as much as possible—normally to a specific gravity between 1025 and 1030. In this test the maximum concentration affords the best criterion of the reabsorption of water in the tubules, and therefore of one of the chief functions of the tubules. It is interesting to consider the principal symptoms of Bright's disease in the light of this modification of Cushny's filtration theory. With regard to albuminuria, it is well known that the greater part of the protein excreted in the urine is serum albumin, excreted because of an abnormal permeability of the glomeruli. The loss of albumin in albuminuria is of prime importance in the production of oedema because of the altered physical condition of the plasma. Polyuria can be explained as the result of diminished water absorption in the tubules. The authors pay particular attention to chronic uraemia, the symptoms of which are certainly due to the retention of nitrogenous bodies. In severe cases of uraemia it is possible to improve the symptoms by restricting the nitrogen metabolism without, however, effecting any real improvement in the renal function. The nature of the nitrogenous substance which causes the toxic symptoms is unknown. Urea and creatinin appear to be quite atoxic when by administering them their concentrations in the blood are brought to the same height as, or above, those found in severe uraemia. There is no doubt that genuine uraemic symptoms occur with

[1] *Acta Medica Scandinavica*, 1931, vol. lxxiv, Fasc. 5.

different degrees of azotaemia in different individuals. The acidosis and low calcium content of the blood in true uraemia are probably secondary factors. From their studies of restricted protein diet and uraemic symptoms Holten and Rehberg deduce that uraemic symptoms disappear quickly when the glomerular filtration is fairly well maintained, and slowly when it is small, and that they persist when it is greatly decreased. The blood urea can be influenced by diet most when the glomerular filtration is fairly well maintained, and least when it is bad.

NOMENCLATURE OF PYORRHOEA

At the International Dental Congress, to be held in Paris next August, a special sectional discussion will take place on the nomenclature of pyorrhoea, and it seems likely that the British and the Continental view will be sharply contrasted. At a meeting of the Section of Odontology of the Royal Society of Medicine, held at the Royal College of Surgeons on Monday, May 18th, Dr. E. W. Fish, who acts as secretary of the Section for foreign correspondence, stated that an attempt has lately been made in Holland to frame a better nomenclature for the group of diseases called pyorrhoea than that which at present obtains. The trouble with this group of diseases, said Dr. Fish, was that every worker in this particular domain almost always devised new names to suit his own views of the etiology of the condition, and it was felt by a number of Dutch workers, who were trying to divide the disease up into the various clinical manifestations, that it was first of all necessary to arrive at some nomenclature free from any reference to the etiology of the disease and merely to describe the conditions seen in the mouth. With that object in view a committee in Holland set to work, and had endeavoured to devise names which would be acceptable internationally. The suggestions so far made—which were quite tentative—were that pyorrhoea should be divided into three groups—namely, gingivitis marginalis suppurativa, peridentosis, and alveolar atrophy. The first group would consist obviously of a superficial inflammation of the gum margins indicated by the reddened edge of the gum. Peridentosis was taken to include diseases in which there was loss of tissue around the teeth. It was proposed to subdivide this group into three classes—namely, peridentosis profunda, really the later stage of gingivitis, in which there were pockets and pus; peridentosis dystrophia diffusa, in which there was an irregular loss of bone, with loosening of teeth; and, finally, peridentosis dystrophia complicata, in which there were pockets, pus, and wandering or loosening of teeth. The third category, alveolar atrophy, included the conditions in which the loss of tissue was definitely associated with age (many workers would not regard these as diseases at all) and might be subdivided into atrophia praecox and atrophia senilis. Mr. F. N. Doubleday hoped that in this country no such classification would be accepted. It might fairly be observed, he said, that a somewhat similar classification had come from Vienna, and from Toronto and New York. The objection to these classifications was that they were based on the Continental conception of pathology—that is to say, on certain morbid appearances, and not on the pathological conception as it was understood in this country. Pyorrhoea might be divided simply into two groups: that which was due to some local cause, which was under control and would yield to surgical treatment; and that which was due to constitutional causes and must be correspondingly treated. Mr. Doubleday added that a great deal of pathological work had been done in the Section of Odontology, particularly by Sir Frank Colyer, on the infective organism, and he hoped that the British delegates at Paris would not agree with the proposed Continental nomenclature.

THE ROYAL SOCIETY CONVERSAZIONE

Standing behind the mace presented to the Royal Society by King Charles II in 1663, the president, Sir Frederick Gowland Hopkins, received guests at the conversazione held at Burlington House on the evening of May 20th. If Samuel Pepys, Esq., F.R.S., had been one of the guests he would, one feels sure, have been "full of admiration, all admiration," as was the Duchess of Newcastle, who, "after much debate pro and con," attended a meeting of the Royal Society on May 30th, 1667, and was shown "several fine experiments . . . of colours, loadstones, microscopes, and of liquors; among others, of one that did while she was there turn a piece of roasted mutton into pure blood, which was very rare." Pepys would have seen all these experiments except the last one, which is still very rare. With so many exhibits of such divergent interest as "the somatic induction of polypoids" and "the application of the methods of *x*-ray crystal analysis to industrial problems," the visitor felt an urgent need for the Dioptrical Paradox (Exhibit No. 17) which will "refract to the eye the various parts as one entire figure to be represented." Perhaps that which, as much as anything else, distinguished this meeting from those held in the seventeenth century was the part taken by industry in the demonstration of experiments on loadstones and liquors. The projection of films showing the application of substandard cinematograph apparatus to the study of crystal growth was one of the exhibits of Imperial Chemical Industries, Ltd.; fused quartz mirrors were shown by the Thermal Syndicate, Ltd.; and Messrs. Vickers-Armstrong, Ltd., had on view a new model projection microscope which will take heavy objects up to 50 lb. in weight, which is immune from vibration, and which can be used for the examination of transparent or opaque specimens at magnifications of from three to five thousand diameters. That the cell in the developing embryo is predestined to one organic fate, and one only, would seem to be disproved by the work of Mr. C. H. Waddington from the Strangeways Research Laboratory, Cambridge. A series of beautiful microscopical specimens showed that in avian embryos a developing primitive streak can induce a neural plate in ectoderm which does not normally form such a structure; and, furthermore, that the primitive streak itself can be regenerated even after it has been removed. Another very interesting exhibit from the same laboratory demonstrated that exposure of tissue cultures to lethal doses of gamma rays produced the same result, given either in one continuous irradiation of six hours or in hourly fractions on six successive days; the action is cumulative. But if a shorter irradiation, merely hindering cell division, is given, the action is not cumulative, and its effect varies with the length of the interval between the irradiations. The interest shown

by the guests in casts of the skull of the Peking man, and in the fossil remains of the Taungs ape, testified to the fascination of the anthropological jigsaw puzzles which are adduced as evidence of man's origin. Professor G. Elliot Smith, in a note on the cast of the Peking man, prepared by Professor Davidson Black, pointed out that the absence of a projecting mastoid and the unusual form of the robust tympanum more closely resembled the simian condition than any known human skull, while the articulation of the lower jaw approximated to the formation regarded hitherto as distinctive of *homo sapiens*. The two outstanding features of the evening, however, were the cinematograph films of virus diseases of plants and of a new process of colour photography on non-inflammable film. The first showed the changes taking place in the cell of the plant *Solanum nodiflorum* after infection with a virus. With a magnification of twenty thousand, and at a speed of twelve times the natural rate, the protoplasm was seen to move round the confines of the cell and along the strands intersecting the body of the cell, while the nucleus was jostled along by this never-ceasing cytoplasmic stream. The first effect of the virus was an acceleration of the movements of the cell contents. Then, passively carried about the cell by the moving cytoplasm, numerous small protein particles appeared, which tended to congregate in the neighbourhood of the nucleus. In the end they coalesced to form a single rounded mass, or inclusion body, usually closely adjoining the nucleus. In one cell an inclusion body was shown to be separate from the nucleus. Dr. W. B. Brierley, who was demonstrating the film for Dr. F. M. L. Sheffield, emphasized that the inclusion body was non-motile, was not a living entity, and was an aggregate of particles giving a protein reaction. After a time this body tends to break down into a number of protein crystals. It is impossible to do justice in a short space to the work of Mr. S. R. Wycherley and Mr. T. Thorne Baker, members of the technical staff of Messrs. Spicer, Ltd. In their new process, coloured objects are photographed in an emulsion coated over a matrix consisting of some half-million red, green, and blue-violet squares to the square inch on non-inflammable film. The advance on previous colour photography was well shown in a series of interesting cinematograph films of Piccadilly Circus, of the French Riviera, of the Royal Botanical Gardens, of the gardens of the Zoological Society, and, to the delight of the audience, of Sir Frederick Hopkins at work in his laboratory. In the "close-ups" of flowers one saw excellent examples of the delicate gradations of colours obtained by this process; the only difficulty that remains to be overcome is the diffusion of blue in open scenes. And so to bed after having enjoyed, with the shade of Pepys, "a great meeting of worthy noble persons."

PLAGUE IN ECUADOR

Plague was introduced into the West Coast of South America in 1903, when a vessel from India brought it to Peru. About five years later it was carried to Ecuador. Since then nearly 8,000 cases have been officially reported from the port of Guayaquil, latterly becoming stabilized at about 110 cases yearly. When the disease first got a footing there were about 300 cases yearly, and the gradual decline, as shown by a recent report of the United States Public Health Service,[1] is probably due to a reduction in rodent plague consequent upon an increasing immunity of rats to the infection. The disease has of course spread from the port to inland towns and villages, but it is believed that the extermination of plague in Guayaquil will mean its extermination throughout the country. Pneumonic plague is rare, and septicaemic plague is not common. The usual form is bubonic plague, as in most other countries, but axillary buboes are very frequent. In addition, especially in the mountain districts, a tonsillar form (angina pestosa), and a vesicular form (viruela pestosa), resembling chicken-pox and small-pox, are often encountered. The first of these special varieties is probably due to the habit of the Indians of killing vermin with their teeth; it is unknown why the second atypical form occurs. The important form, however, is the ordinary bubonic plague, which has a relatively low mortality—about 36 per cent. The main cause of the condition is the tropical rat flea (*Xenopsylla cheopis*) in the areas where rats comprise the important reservoir. But it is believed that *Pulex irritans* is the main cause in the mountain regions, and is probably instrumental in carrying it from man to man; it is probably the main cause of the two atypical forms. The plague reservoirs, in Ecuador as elsewhere, are rodents, and although guinea-pigs are extensively kept in houses, the important rodent is *Rattus norvegicus*. Few towns are more suitable for the establishment of rat colonies than Guayaquil. There are a very few concrete buildings more or less rat-proof; a considerable number of cheap bamboo shacks which from the poorness of their construction offer little rat harbourage; and many blocks of wooden buildings which offer almost ideal conditions for rats. Those occupied by the poorer classes are overcrowded to an unbelievable extent with human beings and with guinea-pigs. Hygiene is poor; and, to add to the complications, the elaborate death ceremonies of the Indians keep relatives, from long distances, in close contact with the body for several days—often lying on the floor in a drunken stupor most of the time. Finance made it impracticable to insist on rat-proof buildings, but towards the end of 1929 a small Government grant was provided for antiplague measures. This was expended in trapping and poisoning rats. The use of poison has been in practice in many places before; but this method has seldom been employed with the intensity adopted in the past few months in Guayaquil. The poison—arsenic or barium carbonate with a suitable bait—is made up in small paper packages by boys and sprayed with oil of anise before being stored in barrels for subsequent distribution throughout the town. The best bait was found to be dried fish, corn meal, and arsenic. Barium carbonate is slightly less effective as a poison, and more has to be used in a package (35 per cent., against 18 per cent. of arsenic), but it has advantages when poisons are first being introduced, because of its lesser toxicity to the general population. No accidents have occurred in the town during the campaign, except the death of some ten cats, which had been attracted by the fish baits. The

[1] U.S. Treasury Department. Public Health Service. *Chief Etiological Factors of Plague in Ecuador and the Anti-Plague Campaign.* By C. R. Eskey. Reprint No. 1409 from the Public Health Reports. Washington: Government Printing Office. 1939. 15 cents. (For sale by the Superintendent of Documents, Washington, D.C.)

oil of anise used seems to have an attraction for rats, but not for other animals. The results of the use of poison show that it is an inexpensive, safe, simple, and effective procedure to employ in any antiplague campaign. So successful has it been that it is anticipated that, without any other measures whatever, if the poison campaign is continued with the same activity as during the past seven months, plague will be eradicated from Ecuador within a year.

MEDICAL PROBLEMS OF CLIMATE AND AIR TRAVEL

In a previous note in these columns (December 20th, 1930, p. 1055) on medical research at the Eppendorf General Hospital in Hamburg, mention was made of the special "pneumatic rooms," where the air pressure could be varied within wide limits. The suitability of these pressure chambers for investigation of many outstanding physiological and medical problems has led to the founding of a special research institute concerned with problems relating to air travel and climatic conditions. In conjunction with other research departments in Hamburg, it is proposed to investigate at various "heights" (that is, at various degrees of atmospheric pressure) the general efficiency of air pilots and air travellers at rest, at work, after training, and after periods of recuperation. Observations will be made on the functional efficiency of the heart, lungs, kidneys, special senses, nervous system, etc., under these conditions. Ergometry and balance experiments, measurement of metabolism of the power of concentration and latent period, will also be carried out under different degrees of reduced atmospheric pressure. Particular attention will also be paid to the medical aspects of air-, sea-, and mountain-sickness. The optimum efficiency of human beings under varying atmospheric states will be investigated, in association with the meteorological institute in Hamburg and the light research institute at the Eppendorf Hospital. The influence, on several groups of subjects, of atmospheric pressure, degree of humidity, water-vapour tension, temperature, radiation from the sun, wind, and electrical charge, will be observed. The physiological behaviour of healthy persons both at rest and at work, and of patients suffering from various diseases under the conditions outlined above, will be studied. By means of the climatic conditions artificially produced in the pressure rooms, methods will be devised for testing the suitability of tuberculous patients, for example, for treatment at high altitudes. Sudden climatic variations, and the importance of acclimatization on the physiological state of subjects at work and at rest, will also come under consideration; while the investigation and treatment of caisson disease and bronchial asthma, for example, by high pressure, will also be carried out. In conjunction with other departments of the Eppendorf Hospital it is also proposed to conduct, at very low pressure, a series of animal experiments bearing upon the question of stratosphere flying, now much before the public eye in Germany. Problems connected with anoxaemia, acapnia, greatly reduced temperature, and artificial respiration apparatus for the administration of oxygen are particularly those with which modern air travel is concerned, as well as with those more special problems of the effect of high altitude and high speed on balancing power and sense of position. It is hoped that the new institute in Hamburg will eventually be able to throw some light on these comparatively unknown regions of human physiology.

DR. BARNARDO

A valuable record of the life of a great man who was a member of the medical profession will be found in a book entitled, *Dr. Barnardo: Physician, Pioneer, Prophet*,[1] by Dr. J. Wesley Bready. It is a refreshing volume, interesting throughout, and even fascinating in that portion of it which tells of Barnardo's discoveries of the homeless boy population of London and of his early efforts to make their existence known to others, and to deal with the appalling situation. The subtitle of the book, "Child Life Yesterday and To-day," is appropriate, for the work and achievement of Dr. Barnardo lay not only in the establishment of an organization and institution which is one of the great monuments of modern philanthropy, but in the change which his influence and action has very largely helped to bring about in regard to child welfare, to the custody of children, and to Poor Law homes and schools, as well as in connexion with the migration of children to the oversea Dominions. A fine tribute was paid to his work by the chairman of the Local Government Board's Departmental Committee in regard to Poor Law children when he said: "Most of the reforms that the committee has recommended Dr. Barnardo had anticipated and put into practice. We owe him much for what he has done. I think we owe him more for the example he has set us of how to do it." Not only does Dr. Bready vividly record a large number of striking episodes, but he succeeds also in presenting a complete picture of the man, stirred by evangelical faith and humanitarian pity, who shirked no danger and steadfastly met all sorts of opprobrium in the cause which he had adopted as his life-work. He was a remarkable reformer and organizer, impetuous and obstinate, autocratic and self-sacrificing, with a rare vision and an abundant human sympathy—a personality, in fact, of which any profession and any generation might be proud. To this account of Barnardo's life and work is attached an admirably characteristic portrait taken shortly before his death.

We much regret to announce the sudden death, at Whitsuntide, of Sir Herbert Waterhouse, consulting surgeon to Charing Cross Hospital and president of the Medical Defence Union. We hope to publish an obituary notice next week.

We regret to record the death of Dr. A. T. MacConkey, late bacteriologist in charge of the serum department, Lister Institute of Preventive Medicine.

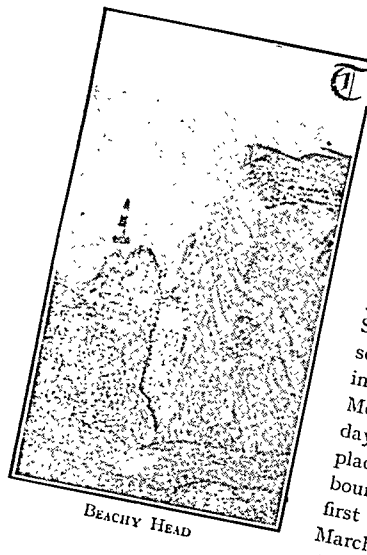
The President of the Royal Society, as chairman of the General Board of the Laboratory, will receive visitors at the National Physical Laboratory, Teddington, on the afternoon of Tuesday, June 23rd.

[1] *Dr. Barnardo: Physician, Pioneer, Prophet.* By J. Wesley Bready, Ph.D.Lond., B.D.Toronto. London: Hodder and Stoughton, Ltd. 1931. (Pp. 271. 7s. 6d. net.)

NINETY-NINTH ANNUAL MEETING
of the

British Medical Association

EASTBOURNE, 1931



BEACHY HEAD

THE ninety-ninth Annual Meeting of the British Medical Association will be held at Eastbourne this summer under the presidency of Dr. W. G. Willoughby, medical officer of health for Eastbourne, who will deliver his address to the Association on the afternoon of Tuesday, July 21st. The sectional meetings for scientific and clinical work will be held, as usual, on the three following days, the morning sessions being given up to discussions and the reading of papers, and the afternoons to demonstrations. The Annual Representative Meeting, for the transaction of medico-political business, will begin on the previous Friday, July 17th. The provisional programme for the work of the fourteen Scientific Sections, together with the full list of presidents, vice-presidents, and honorary secretaries of the Sections, and the time-table of social events, was published in the *Supplement* of May 2nd. Other details of the arrangements for the Annual Meeting will appear in later issues. During the week, and in particular on the last day of the meeting (Saturday, July 25th), there will be excursions to neighbouring places of interest. We publish below, the third of a series of articles on Eastbourne and its neighbourhood, with special reference to medical institutions. The first article—"Eastbourne in History and To-day"—appeared in our issue of March 14th (p. 464), and the second—"The Hospitals of Eastbourne"—on April 11th (p. 637).

THE SURROUNDINGS OF EASTBOURNE

It is convenient for the purpose of a brief description to divide the country round Eastbourne into three sections. The first is the Downs section south-west of the main road to Lewes; the second, the region between that road and the main road to Tunbridge Wells, which is nearly due north of Eastbourne; and the third comprising the country to the east of the Tunbridge Wells Road.

THE DOWNS

The road to Lewes passes through Willingdon and Polegate, where it leaves the London Road and proceeds to Wilmington. All the way to Lewes the Downs are close at hand on the left. At Wilmington there is the famous "Long Man" cut in the turf. He holds a staff in either hand, unless, as has been suggested, the upright strokes represent doorposts. The symbolism, as well as the origin, of the figure is a matter of controversy. Here also are the remains of an ancient priory, on the right of a branch road leading to Lullington, Litlington, and Exceat. The church at Lullington claims to be the smallest in England; it is, however, but the chancel of a larger church, the rest of which has fallen into ruin. Beyond Wilmington the main road passes over the River Cuckmere (pronounced "Cook-mere"). A short distance down the river may be seen Alfriston (Alfred's or Alfric's town), whose church, the largest of the Down churches, has been called "the cathedral of the Downs." Other noteworthy features are the old Market Cross and the Star Inn. Between Alfriston and Seaford, on the coast, the road ascends a steep hill, appropriately named "High-and-Over," from the summit of which a fine view of the Cuckmere Valley can be obtained. The next village on the Lewes Road is Berwick, pronounced as spelled. It is customary in Sussex, in the pronunciation of its place-names, to give each syllable its full value, even the suffix "ham," being pronounced quite distinctly—for example, Etching-ham, not Etchingum; a final —as in East Hoathly or Hellingly, is pronounced long. Between Berwick and Selmeston a short by-road on the left leads to Alciston, where there is a footpath over the Downs to Seaford; another side road in the same direction, a few miles further on, leads to Firle, beneath Firle Beacon (700 feet). At Beddingham, where the Lewes Road bears to the right, the Downs are visible on both sides. The road crosses Glynde Reach, a tributary of the Ouse, and the railway climbs up the side of the Downs and descends to the bank of the Ouse, which is crossed shortly afterwards in Lewes itself. At their confluence, and for some distance above, both the Ouse and Glynde Reach are tidal. From this point the distance to the sea by river is about nine miles.

Lewes, the county town, is full of interest. Dominating it is the castle of Simon de Montfort, to whom was addressed the ode beginning

Salve Simon Montis fortis,
tocius flos militiae.

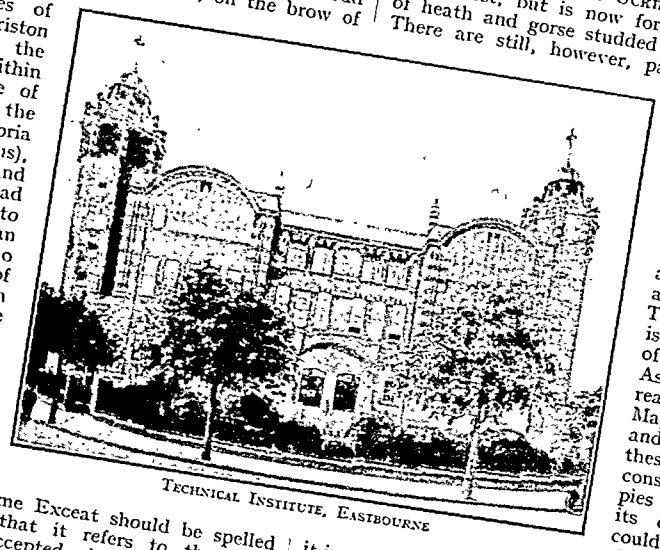
"Tocius," pronounced to scan, will appeal to those who have been chastised for false quantities, unless it is intended to be Lucretian. At the top of a hill rising steeply from the river is the county hall, containing the assize courts, then Castlegate and the Barbican, and further along High Street on the same side the official church of St. Michael-in-Lewes, which has a twisted spire similar to that at Chesterfield, though the twist is less extreme. At the top of Castlegate is a small promenade facing up the Ouse Valley. Below this viewpoint, on the right, is the brick-built church of St. Johnsub-Castro. The exterior is somewhat grim and barrack-like, but still more grim are some of the headstones in the churchyard, which bear death's heads and other gruesome devices in relief.

Two roads lead from Lewes to Newhaven, one on each side of the Ouse. Both pass through picturesque villages, the eastern through Tarring Neville, the western through Southease and Piddinghoe. Each of these villages has a church with a short spire—Tarring Neville pyramidal, Southease conical, and Piddinghoe hexagonal. The mellow

lichened roofs of Tarring Neville are very pleasing to the eye. From Southease a by-road crosses the river and the railway (Lewes to Newhaven branch) to join the eastern road leading to Seaford. Newhaven, at the mouth of the Ouse, is well known to many who cross the Channel. Though Seaford has the appearance of a modern seaside resort, it is an ancient port with a history; witness the punning epitaph upon Sir N. Pelham, which concludes with the lines:

What time the French sought to have sack't Sea Foord,
This Pelham did repel 'em back aboord.

The more direct route from Eastbourne to Seaford is over the Downs, leaving Eastbourne either by Old Town and up East Dean Hill, or at the western end of the Parade and by the Duke's Drive, which also leads to Beachy Head and Birling Gap. Beachy Head is famous enough to need no description here; Birling Gap is the only place between Eastbourne and the mouth of the Cuckmere where the cliffs are low enough to give an approach to the shore. The first villages on the road are East Dean, in a valley, and Friston, on the brow of the hill above it. Both have small churches of great antiquity. At Friston a road branches to the right for Jevington (within easy walking distance of Eastbourne, over the Downs from the Victoria Drive bus terminus). Wannock, Willingdon, and Polegate. The main road continues westward to Exceat. West Dean can be seen off the road to the right, in a hollow of the Downs. Exceat is on the Cuckmere, half a mile from the mouth, which may be reached by a footpath along the further bank. The river flows cut into the sea partly in an open channel and partly by percolation through the shingle. Some have suggested that the name Exceat should be spelled "Exeat," on the ground that it refers to the river mouth; but the generally accepted view is that it is a Saxon word. It is difficult to see why, if Latin, it should be in the subjunctive. The Downs rise again from the western bank of the Cuckmere, and Seaford is soon reached. Beyond Seaford and Newhaven the road continues along the cliffs through Peacehaven, Saltdean, and Roedean, to Brighton—some twenty-one miles from Eastbourne.



TECHNICAL INSTITUTE, EASTBOURNE

BETWEEN LEWES AND TUNBRIDGE WELLS

Between the Lewes Road and the Tunbridge Wells Road lies country which—until Ashdown Forest is reached—is less characteristic of Sussex, but is by no means devoid of interest. Ashdown Forest, through which the London Road passes, will be referred to later. On the western side of this region lies the valley of the Upper Ouse, here neither tidal nor navigable, except for small pleasure craft. A little to the north-east of Lewes is Ringmer, and to the south-east Glynde, joined by a picturesque and hilly road. East of these, and very close together, lie the villages of Ripe and Chalvington, occupying the centre of a flat and thinly populated area to the north of the Eastbourne-Lewes Road, and bounded on the east by the Cuckmere. On the Eastbourne side of the Cuckmere, and reached by road, either from the London Road just south of Hailsham, or from the Lewes Road by turning right at Wilmington, is "The Hide," more fully Milton or Arlington Hide, a large common dotted with gorse bushes, and forming a verge to the large and dense wood known as Abbot's Wood. The latter is well known to entomologists, who find in it a hunting ground scarcely inferior to the New Forest. The wood is private, but permits can be applied for. An idea of its extent can be most readily obtained from the top of the Downs above the Long Man of Wilmington. On the opposite side of the Hide is a road leading to Michelham Priory (whose ancient gateway is approached by means of a bridge over the Cuckmere) and the villages of Upper and Lower Dicker. Hailsham is a market town about eight miles from Eastbourne. Some two miles further is Horsebridge, a road junction with two dangerous corners; here roads lead to London, Tunbridge Wells, and Hastings. The Cuckmere is crossed between the two corners.

North of a line drawn from Lewes to Horsebridge, as far as the high ground of North Sussex, the country is gently undulating and well wooded. The only town is Uckfield; in this region the population is distributed in isolated farms and houses and in small villages, such as Chiddingly and East Hoathly. Ashdown Forest begins a few miles north of Uckfield. In olden days it was a true forest, but is now for the most part a high moor of heath and gorse studded with groups of fir and pine. There are still, however, parts of the old forest in all their density, especially near Worth. The remainder went to smelt Sussex iron before the age of coal. Crowborough, some nine miles from Uckfield, is the highest town in the county, and the journey by road to this, or indeed any, point in the forest affords magnificent views. The Tunbridge Wells Road is somewhat to the east of the main part of Ashdown Forest, but reaches high points at Mayfield, Mark Cross, and Frant. The first of these three is especially conspicuous, since it occupies the top of a hill of its own. Though much could be written about the forest and its history, its towns, and its villages, it is somewhat far afield from Eastbourne, and we have yet to notice the country east of the Tunbridge Wells Road, a region of perhaps even greater interest, since it abounds in relics of Roman, Saxon, and Norman times, and includes the actual site of the Conqueror's decisive battle.

EAST OF EASTBOURNE

Eastward from Eastbourne lie some twelve miles of level country, with the low hill of Pevensey in its midst. Pevensey was once an island; what are now marshes were covered by the sea, which in receding has left Pevensey a mile inland. Its strategic position was recognized by the Romans, and later by the Normans. Pevensey Castle, lately taken over and extensively restored by the National Trust, is a Norman castle within Roman walls. The most likely site of the Roman Anderida is here, though other conjectures have been made, including Eastbourne itself. Adjoining the Castle is the old Mint House. Not far from Pevensey, where Wartling Hill rises off the eastern edge of the levels, is Hurstmonceux Castle, which was the first brick building of consequence erected in England.

From Heathfield, a town about eighteen miles north of Eastbourne, and just off the Tunbridge Wells Road, a ridge of hills, continuous with the Ashdown Forest range, runs south-east, to terminate in the Hastings cliffs. This ridge borders the Pevensey Levels, and Wartling Hill is one of its lower slopes. Before proceeding further east we should notice the country upon and behind this ridge. Heathfield is a pleasant little town, increasing in size as its attractions become better known. To the east, Dallington stands on a hill in much the same manner as does Mayfield, already mentioned. The Cuckmere rises between Heathfield and Dallington. Brightling Beacon,

near Dallington, and at an altitude of 620 feet above sea-level, is a conspicuous landmark and an observation point for the coast from Beachy Head eastwards along Pevensey Bay. On the seaward side of the ridge are Warbleton and Penhurst, on the landward side Burwash; the hills and valleys around them are not overcrowded with traffic, and, being within easy reach of Eastbourne, make a good objective for a quiet tour. The road along the ridge next leads to Battle, which is reached more directly from Eastbourne via Pevensey, whither we will therefore return.

Continuing eastward from Pevensey, we may take either the Wartling or the Hooe Road to cross the remainder of the marshes. The latter is the more direct for Battle or for Bexhill and Hastings. On the right a by-road leads to Norman's Bay, nominally the site of the Conqueror's landing. The visitor approaching Hooe will observe a couple of oast-houses built on the hillside. These buildings are a prominent feature all over this part of Sussex, where the hop industry was extensively carried on. Hops are still grown in Sussex, but less than heretofore. The site of the famous battle of 1066, usually called the Battle of Hastings, is Senlac Hill, near the town of Battle, and about seven miles north-west of Hastings. The ancient building of Battle Abbey, which William the Conqueror founded as a thank-offering, was recently damaged by a disastrous fire. To the north-east of Battle, some seven or eight miles distant, is Bodiam Castle, one of the best-preserved fourteenth century castles in England. It stands on the north bank of the Rother, and its ancient moat is still water-filled. The castle was the property of the late Marquess Curzon, who left it to the nation. Hastings, one of the Cinque Ports, is too well known to call for description. It also has an ancient castle, on the heights to the east of the town. Beyond Hastings are Winchelsea and Rye, which both deserve a visit.

CONCLUSION

To attempt to do justice to Eastbourne's surroundings in such a limited compass is impossible. Sussex, with its long coast-line, its wide diversity of scenery, its venerable history, and its sunny climate, has no lack of panegyrists in prose and verse, and if this short description of a part of the county assists intending visitors in making their own explorations, it will have served its purpose.

Nova et Vetera

LEONARDO DA VINCI AS ANATOMIST

The steps which have given us Professor McMurrich's book about Leonardo da Vinci[1] are as numerous and as complicated as those involved in the production of the proverbial loaf of wheaten bread. There is first the apprenticeship of Leonardo to a painter in Florence in 1472, the apprentice being at that time 18 years of age. Then there were visits to the post-mortem room of a hospital in Florence, where the apprentice became interested in the internal structure as well as the outward form of the human body. In the third place, there was the growth of a curious habit in the apprentice of registering what he saw by means of marvellous sketches—adding to them hurried notes of his interpretation of anatomical appearances. At the time of his death at the age of 67 his folios and notebooks numbered 120; they were the material out of which he was to construct a complete account of the natural history of the human body. Death stepped in before he began his final task, and his harvest of hieroglyphs, of which he only had the key, was scattered abroad in Europe. Part of it went to Spain, and when the prince who afterwards became Charles I went wooing there in 1623, although he failed to find a bride, he did capture a large and valuable part of the Leonardo documents, which duly found their way to the Royal Library at Windsor. Others turned up in Italy and France.

The steps just narrated refer to the sowing of the Leonardo harvest; to explain those which have led to the gleaning and the production of this very solid loaf of a book it is necessary to pass to the nineteenth century, when a young Scot named Andrew Carnegie made a home and a fortune in the United States of America. Part of that fortune went to the establishment of the Carnegie Institute in Washington. In 1918 the president of the Institute invited Dr. George Sarton to write the history of science. He soon perceived that Leonardo da Vinci was one of the scientific giants of the fifteenth century, and that to assess the value of his contributions to anatomy it was necessary to call in professional assistance. He wisely went to Toronto, and enlisted the services of that distinguished anatomist Professor McMurrich, who has just sought retirement after being known to two generations of medical men by important contributions made to the embryology and anatomy of the human body. In writing this book, which represents a labour of ten years, Professor McMurrich has had at his command all known anatomical records made by the great artist. Never before have medical men had at their disposal the means of forming a just opinion of the greatness of Leonardo as an anatomist. The opinion formed by the reviewer is that, high as the author has placed him, the pedestal given is not equal to Leonardo's deserts.

It may seem ungracious, where so much is admirable, to cite a minor slip made by Professor McMurrich in one of his opening chapters. Writing about the Leonardo drawings preserved at Windsor our author states (p. 68):

> "When the rediscovery was made the book was brought to the attention of John Hunter, then the most outstanding English anatomist, and in his *Two Introductory Lectures*, published in 1784, he mentions the anatomical drawings with high appreciation. . . . A little later they were inspected by Blumenbach."

Those who are acquainted with the writings and life of John Hunter will be surprised to find him extolling the works of dead anatomists. He had very decided opinions of the value of their books. He held that their true value was to be assessed, not by what was read into them by "moderns," but by the opinion formed and appreciation expressed by the generation to which such works were addressed. In John Hunter's opinion, a discovery was valid only when it became the starting-point of a development of new knowledge; if it fell dead it did so because the discoverer did not understand what he had found. This is certainly not true of several discoveries made by Leonardo; he understood and demonstrated many things which should not have had to wait four centuries to be appreciated at their full value. Leonardo wrote in a new way, using hieroglyphical drawing as his medium of expression.

The man who recognized the great merits of Leonardo was John Hunter's elder brother William. He was certainly the greatest *human* anatomist produced by England in the eighteenth century. He also built up a great museum—a priceless collection of manuscripts, a unique collection of ancient coins—all of which are now preserved in the University of Glasgow. He was a man-midwife, the author of *The Gravid Uterus*—with its superb plates. In the course of his professional attendance on the Royal Family he had often to pass days at Windsor Castle awaiting "interesting events." It was

[1] *Leonardo da Vinci, the Anatomist (1452–1519)*. By J. Playfair McMurrich, Professor of Anatomy, University of Toronto. London: Baillière, Tindall and Cox. 1930. (Pp. xx + 265; 89 figures. 27s. net.)

during one of these visits, probably in 1782, that "Mr. Dalton, the King's Librarian, informed me of the discovery of these drawings, and at my request procured me the honor of leave to examine them. . . . In due time I hope to engrave and publish the principal of Leonardo's anatomical designs. They will be a curious and valuable acquisition to the history of Anatomy." Alas! death again stepped in, and deprived Leonardo of the anatomist more fitted than any other to be his commentator. As is well known, William Hunter gave his last course of lectures in his school in Windmill Street in 1782–83; he died soon after bringing the course to an end. In the opening lecture of his last course, which was published by his executors the year after his death, he announced the discovery of Leonardo's drawings, and gave his opinion of them in the following words:

"In tracing the great revolution in learning, which happened in the 15th century, I am enabled to carry the history of the improvement of anatomy farther back than has been done generally by our own writers, and to introduce into the annals of our art a genius of the first rate, Leonardo da Vinci, who has been overlooked because he was of another profession. *I believe he was by far the best anatomist and physiologist of his time*, the first man we know of who introduced the practice of making anatomical drawings. I saw, and indeed with astonishment, that Leonardo had been a general and a deep student. When I consider what pains he has taken on every part of the body, the superiority of his universal genius, his particular excellence in mechanics and hydraulics, and the attention with which such a man would examine and see objects he was to draw, I am fully persuaded that Leonardo was the best anatomist at that time in the world."

William Hunter was a man who weighed his words; so does Leonardo's present editor; the opinion the one came to in 1782 regarding Leonardo's merits is almost the same as the other has come to in 1930, save perhaps that the flash of insight lies with the eighteenth century anatomist rather than with his modern successor.

A survey of the documents which Professor McMurrich has placed before his readers astonishes the critic by revealing Leonardo in two quite different lights. His drawings of the articulated human spinal column are masterpieces of accuracy—notwithstanding the extra spinous process to which Professor McMurrich has drawn attention! The length, inclination, and shape of every vertebral process—spinous and transverse—are introduced with more than photographic accuracy. The man who depicted so unerringly the varying length and inclination of the transverse processes of the dorsal vertebrae had evidently fathomed the significance of the series in its relation to respiration. Yet modern textbooks leave the functional significance of the arrangement of these processes unmentioned. He approached the study of the backbone and of its musculature with no preconceptions, and drew with unerring truthfulness. But when he approached the study of the heart and great vessels he diagrammatized so as to make the parts fit with Galen's conception of the circulation. Even one of the greatest and most original minds twisted facts to suit a theory—a warning for all time.

If anyone wishes to realize how modern—nay, ultra-modern—Leonardo could be, let him look at the plate which provides Professor McMurrich with Fig. 12. A series of studies is given representing the part played by the muscles round the hip-joint in maintaining the body erect. In two drawings the muscles have been removed and their place taken by bands or cords to represent the part they play in balancing the body at the hip-joint. One drawing represents the buttock region of a horse rearing on its hind quarters, the other a profile of the left thigh and buttock of a man standing erect. Leonardo clearly realized that in assuming such postures all the muscles act from their lower attachments; the thigh provides their fixed point for action; the hip-bone moves. Yet one will search modern books in vain for his vivid representation of a truth of the utmost value to orthopaedic surgeons. He also realized that in the act of rearing a horse threw into action the same muscles as a man does who raises his body from a stooping to the erect posture.

Only a few scattered grains culled from the great wealth of this book have been placed before the reader—just enough to show the feast which awaits the real student. One might put up a claim for Leonardo as giving better guidance to the orthopaedic anatomy of the human body than has yet been given by any other master. Whether such a claim is justifiable or not, there cannot be any doubt as to the present benefit conferred by the Carnegie Institute on all students of the human body by the publication of Professor McMurrich's *Leonardo da Vinci, the Anatomist*.

A. K.

THE UNITED STATES PUBLIC HEALTH SERVICE

For the information of those desirous of entering the Regular Commissioned Corps a pamphlet has recently been issued by the United States Treasury Department dealing with the history, functions, and organization of the Public Health Service, and also regarding appointments, compensation, promotions, duties, and retirements.[1]

SUMMARY OF FUNCTIONS

The United States Public Health Service has existed since 1798, and until 1902 was known as the Marine Hospital Service. Created originally to provide medical care and treatment for sick and disabled seamen, its functions have been extended to include scientific research and measures for the protection of the public health; these include quarantine duties, the medical examination of aliens, both at home ports and in foreign countries, the study of exotic diseases, and the regulation of inter-State traffic in serums, toxins, and analogous products. In 1901 the construction of the Hygienic Laboratory was authorized for the systematic investigation of infectious and contagious diseases and matters pertaining to the public health; in 1912 authority was given for field investigations of health problems, including sanitation and sewage and the pollution of navigable rivers; in 1918 special authority was granted for the investigation and control of venereal diseases; and during the past two years the Service has been charged with studies of drug addiction and the care and rehabilitation of drug addicts, and also the broad study of mental hygiene. In 1930 laws were enacted for co-operation with other departments of the Government in public health activities, and for the establishment in Washington of the National Institute of Health, successor to the Hygienic Laboratory, for the purpose of scientific research of problems of disease in man and matters pertaining to the public health. Numerous laws have also been enacted from time to time legalizing the policy of co-operation with other Federal agencies and with State and local health authorities in their measures for the prevention of disease and the promotion of the public health, though no details are given of the extent and character of this co-operation.

Nearly 500,000 persons apply annually for medical care and treatment, mostly officers and men connected with various Government marine services, but including lepers, cases of tuberculosis, officers of the Public Health Service, prisoners at United States penal and correctional institutions, and patients at Federal narcotic farms. Hospitals and other relief stations are maintained by the Public Health Service at 155 ports of the United States and its possessions. The marine hospitals number 25, and are operated by 300 doctors and dentists, the daily

[1] Reprint No. 1414 from the Public Health Reports, United States Treasury Department, Washington, 1931. (10 cents.)

average of patients being about 4,000. The annual expenditure of the marine hospitals and other relief stations exceeds 5,000,000 dollars. All the marine hospitals are medical and surgical hospitals, except that at Carville, Louisiana, which is devoted to lepers, and that at Fort Stanton, New Mexico, which treats merchant seamen and others with tuberculosis suitable for treatment in a high altitude. New hospitals have been provided at Detroit and Cleveland, and others are being constructed or have been authorized at San Francisco (500 beds), Galveston, and New Orleans (600 beds), New York (600 beds), Baltimore, and Seattle. Several small hospitals and a field laboratory are maintained for the eradication of trachoma, and other duties include control measures for the sanitation of shellfish-bearing areas and fundamental research of public health problems in laboratories and in the field.

ORGANIZATION OF THE SERVICE

As regards organization, the Public Health Service is under the control of the Treasury Department, and is presided over by the Surgeon-General at Washington, whose acts are subject only to the general supervision and approval of the Secretary of the Treasury and the President of the United States. The office has eight divisions, each in charge of an assistant surgeon-general or medical director, dealing with (1) marine hospitals and relief, (2) domestic (inter-State) quarantine, (3) foreign and insular quarantine, (4) sanitary reports and statistics, (5) scientific research, (6) venereal diseases, (7) mental hygiene, (8) personnel and accounts. Candidates for the Service must pass a physical, educational, and professional examination, have certificates of good character, and their age must be between 23 and 32 years. Applicants may enter for the medical, dental, public health engineering, or pharmacy branches of the Service. Candidates in medicine who have passed the tests of the National Board of Medical Examiners are not required to pass the written professional test. On first appointment the grade entered is that of assistant surgeon (three years' service), higher grades being those of passed assistant surgeon (nine years'), surgeon (eight years'), senior surgeon (six years'), and assistant surgeon-general or medical director. The Surgeon-General is selected by the President. Public Health Officers are commissioned in grades similar to those of the Medical Corps of the United States Army. If an officer is found not to be qualified for promotion for reasons other than physical disability his commission is terminated, six months' pay and allowances in the case of assistant surgeons and one year's pay and allowances for passed assistant surgeons being granted.

PAY AND PROSPECTS

Maximum annual pay and allowances for assistant surgeons are 3,158 dollars, and, independent of promotion, all officers receive as part of their total compensation 5 per cent. of their basic pay for each three years of service, up to 50 per cent. Officers with dependants receive higher pay, the difference in the case of assistant surgeons being about 450 dollars per annum. The maximum basic pay of the surgeon-general is 9,700 dollars per annum, while senior surgeons receive approximately 7,000 dollars. Special allowances are made for travelling, and also for transport expenses on change of station. One month's annual leave of absence is allowed, which may accumulate to the amount of four months. On incapacitation by disease or accident an officer, after the expiration of his annual and sick leave, is retired and placed on permanent "waiting orders" status, and receives three-fourths of his basic pay and longevity increase, irrespective, it would seem, of length of service. On retirement for reasons other than ill-health, senior officers receive up to 60 per cent. of active duty pay.

Officers in the United States Public Health Service are apparently not required to possess any special degree or diploma in public health, and their duties embrace some of those undertaken in Great Britain by the Ministry of Health, port sanitary officers, the R.A.M.C., and, in a minor degree, by local sanitary authorities. The Service is evidently developing rapidly, though the pamphlet does not indicate its relationship to, or degree of co-ordination with, the civil health authorities.

The pamphlet concludes by pointing out that an efficient member of the Public Health Service has a pleasant and useful career, though the pay and allowances are moderate, as compared with some of those in private life. The statement is also made that "a commission in the Public Health Service is not a sinecure, on account of the lack of a fixed dwelling place, the separation at times from the family, and the conditions at times of emergency field service," and that "no officer may expect to amass great wealth through the pay of his commission, but he is assured of a comfortable living and safeguards for disability and old age." Having regard to the greater cost of living in the United States it does not appear that the conditions of service and pay in the United States Public Health Service are superior to those of officers in Great Britain who are engaged in the public services on similar duties.

England and Wales

Detection of Small-pox

The London County Council recently decided that admission of patients to the small-pox receiving station at South Wharf, Rotherhithe (where cases are collected before transport, usually by river, to the small-pox hospitals at Dartford) should be limited to cases in which a medical certificate has been given that the patient is suffering from the disease. Since then representations have been made by the Hackney, Deptford, and Islington metropolitan borough councils protesting against the decision, and pointing out that, in congested boroughs especially, it is most undesirable that a patient whose symptoms suggested small-pox should be obliged to remain at home until the rash has developed sufficiently to enable a definite diagnosis to be made. On the other hand, the London County Council drew the attention of the protesting boroughs to the diagnostic consultant service which it provided, of which some boroughs had not made full use. This service has been established for many years in order to give assistance in doubtful cases. Until about two years ago the duties were performed by a whole-time officer, and since then they have been taken over by a panel of medical superintendents of the fever hospitals. It was also pointed out by the London County Council that precautions must be taken to ensure that patients who have not contracted the disease are not exposed to the risk of such infection by being taken to the small-pox hospital or the receiving station. During 1930 the number of cases sent to South Wharf without a clear certificate of small-pox was 457, of which 94 were proved not to have the disease. In view of the representations made, however, the Central Public Health Committee proposes to modify the regulations, and to instruct that patients suspected as suffering from small-pox, but not so certified, be admitted to South Wharf for observation on the following conditions: (1) that the metropolitan borough medical officer of health has called in to the case one of the council's consultants; (2) that the patient has been examined by the medical officer and by the consultant, in addition to having been examined by the general medical practitioner (in cases in which one has been called in) and that they have all been unable to say definitely that the case is small-pox, although there is a strong presumption in the affirmative; (3) that the application for admission has been made by the borough medical officer of health; (4) that the arrangement whereby borough medical officers obtain information each evening from the Council as to the final diagnosis of cases admitted for observation continues; and (5) that the responsibility for the initiation and carrying out of all preventive action in such cases remains with the metropolitan borough councils.

Occupational Diseases in Coal Miners

In the first of two Chadwick Public Lectures on "The coal miner, his health, and occupational diseases," Professor E. L. Collis dealt with the personal factor in coal mining. He asked his audience to go with him in thought on to a coalfield, while he showed pictorially the way in which the miner worked and earned certain physical disabilities. Miners' nystagmus topped all other occupational diseases added together for which workmen's compensation was paid; it was estimated to cost the mining industry about a million pounds a year. Many more coal miners, on account of their high accident rate, as well as the tendency to certain diseases, claimed compensation every year than did other workers. After nystagmus, the next most frequent disease was beat-knee, followed by beat-hand, beat-elbow, and inflamed wrist. These maladies were due to the way in which the miner used, or rather misused, his body while at work, and they mended rapidly if the fault was corrected. They were far different from miners' nystagmus, with its all-important psychological factor; but in their treatment the aim must be complete restoration of function, so that the miner did not lose his earning capacity. Many mines were not only hot, but deep, and the miner, even though he worked stripped to the waist, perspired freely. Two results might follow: first, his skin was rendered more liable to microbic infection, and he might develop boils; or he might develop cramp if he drank plain water to assuage the thirst caused by free sweating. Miners were exposed to much dust underground, which they could not avoid breathing, so that the lungs of a coal miner became as black as the coal he worked. So long as this dust contained nothing except pure coal no damage resulted, but if rock particles were also present the lungs might be seriously impaired. Some miners only worked upon rock, in cutting roads underground so that the hewers could get to the coal; these men were seriously affected by the dust they created at their work. The dust hazard had been increased by the introduction of pneumatic drills, but a device had been invented for capturing the dust as it was generated. The most serious cause of accidents among miners was falls of roof, due largely to careless timbering of the roof while at work. The mortality rates experienced by coal miners from various diseases, and from accidents, showed interesting variations in different coalfields, and it had been observed that miners tended to be most dissatisfied with their working conditions in those coalfields where the mortality was highest.

Leicester Royal Infirmary

Leicester Royal Infirmary was founded in 1771 by the Rev. Dr. Watts, and its 160th anniversary is commemorated in the annual report for 1930 by a short account of the conditions in England in the second half of the eighteenth century. During the last thirty years three-quarters of a million pounds have been spent in changing Leicester Infirmary from a place which "provided for the needs of the sick for whom no institutional treatment or medical service was available" to a highly equipped modern hospital supported by voluntary contributions. In place of forty-two beds there are now 472. In 1921 4,282 in-patients were treated, and in 1930 the number had increased to 8,008. The ordinary income ten years ago was £51,105, last year it was £83,903. The establishment of a radium department and the installation of an electrocardiograph apparatus are two further examples of the admirable progress made along modern lines by this hospital. It is proposed to make this 160th anniversary an opportunity for a decennial appeal. One of the first works to be undertaken is the enlargement and modernization of the nurses' home.

Scotland

Post-Graduate Courses in Glasgow

The Glasgow Post-Graduate Medical Association will hold a summer session from June till October for post-graduate teaching in Glasgow. The teaching facilities will fall chiefly into two divisions: (*a*) general medical and surgical course, and (*b*) clinical assistantships. During the last two weeks of August and the first two weeks of September a whole-time course in general medical and surgical work will be conducted in the general and special hospitals; for this an inclusive fee will be charged. The mornings will be occupied with general medical and surgical diagnosis and minor surgery, in the Royal Infirmary and in the Victoria Infirmary. In the afternoons special subjects will be dealt with in some of the special hospitals of the city and in special departments of the general hospitals, two subjects being considered each afternoon. In a number of the institutions taking part in this scheme clinical assistantships are available during the summer months as well as at other times of the year; they are designed to make provision for graduates who desire opportunities for a detailed study of one or other of the specialties. Further particulars can be obtained from the secretary, Glasgow Post-Graduate Medical Association, The University, Glasgow.

Health of Dunfermline

In the annual report on the health of Dunfermline for 1930, Dr. C. Barclay Reekie, medical officer of health for the burgh, states that the infantile mortality rate of 51 per 1,000 births for the year is the most favourable on record, and that the general death rate of 11.6 has only once been lower. Although the incidence of infectious disease during the year was higher than the previous year, the number of cases of scarlet fever—namely, 112—represented a decrease of 164; among these cases there was only one death. In one instance the outbreak was traced to a dairy. Cases of diphtheria numbered 91, an increase of 11; one death was recorded. The principal cause of the increase in infectious cases was measles, of which 402 cases were notified—an increase of 277. Three patients, all under 5 years of age, died. In connexion with this disease about four hundred visits in Dunfermline were made by nurses. There were 133 cases of whooping-cough and 315 cases of chicken-pox. Nine cases of malaria were notified, all imported from abroad. Of the seven patients requiring insulin, 3 in necessitous circumstances received the treatment free. Altogether 37,300 units were issued from the public health department. Patients with pulmonary tuberculosis numbered 40; of these, 20 were given sanatorium treatment. During the year 128 patients with this disease, 109 with other forms of tuberculosis, and 20 patients under observation were visited by tuberculosis nurses. The maternity home, established by the town council in 1921 with ten beds, is urgently in need of extension, since 323 patients, whose home conditions were unsuitable, were received during the past year.

Lord High Commissioner and Hospitals

The Lord High Commissioner, Mr. James Brown, M.P., representing the King at the General Assembly of the Church of Scotland, paid the usual round of visits to the hospitals in Edinburgh in the course of the past week. On May 20th he visited the Royal Infirmary, being received by Lady Findlay, chairman of the Board of Managers, and presented the prizes gained by nurses in the recent examinations. On the same day the Lord High Commissioner's wife visited the Royal Maternity and

Simpson Memorial Hospital, which during the past year has treated the largest number of cases in its history. A visit was subsequently paid to the Children's Shelter of the Royal Scottish National Society for the Prevention of Cruelty to Children. In a short address Dr. Harry Miller said that in 1930 the society had dealt with 1,041 cases, involving the welfare of 1,507 parents and 2,978 children; 13,599 visits were paid by inspectors.

Ireland

Public Health in County Meath

In his annual report on conditions of health in County Meath, Dr. T. F. O'Higgins, county medical officer of health, states that the death rate from puerperal sepsis was higher in Meath than in any other county in the province of Leinster. This indicated the absence of skilled attendance at many births, and showed how necessary it was to apply the Notification of Births Acts to County Meath, which was not done by the Board of Health until September, 1930. Mortality from tuberculosis was exceeded only by that from heart disease and cancer, while the death rate from the principal epidemic diseases was 0.32. On the other hand, there has been a marked decline in the death of infants under 1 year, which is attributed to the work of district nurses and nursing associations. In proportion to its population, Meath appears to be better served in this department of public health than other Irish counties. Some reference is made in the report to the general system of water supply throughout the county. With the exception of the three urban districts—Trim, Navan, and Kells—and the town of Slane, where waterworks have been erected, all the towns and villages depend for their water supply on pumps or shallow wells. While pumps are stated to be kept in satisfactory order, the labour entailed in transporting the water often results in shortage and undue economy in its use, and leads to insanitary domestic conditions.

Clean Milk Society

At a recent meeting of the Irish Clean Milk Society, held in Dublin, Sir Edward Coey Bigger, in the chair, declared that if the public was assured that the milk supply was perfectly safe and free from disease, the consumption of milk would undoubtedly be greatly increased. Milk was one of the best and cheapest foods, especially for infants and children, and something had been done to improve it by the use of preservatives. In presenting the report Professor J. W. Bigger of Trinity College, chairman of the committee, said that the Irish Clean Milk Society's activities during the past year had been chiefly educational—for example, in emphasizing the dangers lurking in milk. When the society was founded there were no suppliers of tubercle-free milk in the neighbourhood of Dublin; to-day there were a considerable number who supplied absolutely safe, clean milk—a change that had been brought about largely by the society's efforts. The farmer who took the trouble to supply clean milk would find a market for it. They had failed, however, to secure legislation to improve the milk supply of the country. At present the Irish Free State was behind England, Scotland, and Northern Ireland. Scotland had about one hundred tubercle-tested herds and Northern Ireland about thirty, all under Government control. In this country there were a number of tested herds, but absolutely no Government control. The Inter-Departmental Committee, appointed in 1928, recommended that a system of graded milk should be introduced, and that there should be a penalty for selling dirty milk; yet the Government had done nothing. It was ridiculous that it was safer to sell dirty milk for drinking purposes than to send it to creameries for conversion into butter, largely for export. Even the worst milk could be described as certified in this country. Milk was as important for the health of the baby as water was for adults. In the Irish Free State several hundred babies died every year because they were fed on contaminated milk. These deaths were preventable and absolutely unnecessary. To fail to prevent death was morally the same as murder, and the responsibility rested with every Minister and member of the Dáil and Senate who obstructed in any way the introduction of legislation which tended to improve the milk supply. In proposing the adoption of the report Professor T. Gillman Moorhead, President of the Royal College of Physicians, said that the latest returns from the Public Health Department of the Saorstat showed that while pulmonary tuberculosis was declining surgical tuberculosis was not, and that it would not decline until legislation was introduced to provide clean milk. The society should continue to press for measures to prevent the disease. It was easier and cheaper to prevent infection than to spend a lot of money on cripples as the result of drinking unclean milk.

Mental Hospitals in the Irish Free State

A report presented to the Minister of Local Government and Public Health states that the number of insane persons treated in public and private mental hospitals and other institutions in the Irish Free State in 1929 was 20,050. Of these, 52.2 per cent. were males and 47.8 per cent. were females, distributed as follows: district mental hospitals, 86.7 per cent.; private mental hospitals, 5 per cent.; Poor Law institutions, 7.7 per cent.; and the State Criminal Lunatic Asylum, 0.6 per cent. The daily average number resident in all these institutions during 1929 was 17,273—9,174 males and 8,099 females—and the total number of discharges was 1,283.

INFARCTION OF HEART WITH PERICARDIAL EFFUSION IN A PHTHISICAL SUBJECT

SIR,—The interesting report by Lieut.-Colonel T. A. Hughes and Dr. Mohammad Yusuf (*British Medical Journal*, May 9th, p. 794) of a case diagnosed as infarction of the heart with pericardial effusion in a young phthisical subject has encouraged me to publish a similar history of a patient treated at the Mundesley Sanatorium.

A female patient, aged 36, was admitted on June 13th, 1930. Tubercle bacilli had been present in the sputum for the last eighteen months, during the greater part of which period the patient had undergone treatment in Switzerland. At the time of admission she was afebrile, and her general condition was fairly satisfactory; cough was severe, and purulent frothy sputum amounted to ten ounces in the twenty-four hours. The most remarkable feature of the case was a loud stridor, audible at a considerable distance; apart from a variable number of rhonchi, physical signs in the chest were conspicuously absent, and an antero-posterior skiagram showed heavy hilar shadows, but little else. A lateral *x*-ray picture showed a well-marked opacity in the posterior mediastinum, in which there was some suggestion of clear areas.

The condition remained stationary until August 14th, when pain in the left side of the chest was first complained of. This persisted during the next few days, but was not severe. About 8 a.m. on August 17th there was a sudden attack of agonizing pain, the patient became practically pulseless, and

the heart sounds were faint. Consciousness was not completely lost, but speech and movement were impossible. During the next few days the pain continued, with gradually diminishing severity, and frequent injections of morphine were necessary. The temperature rose to 104° F., and the pulse rate, which had been 72, to 150. An electrocardiogram taken on August 23rd by Dr. H. J. Starling showed no abnormality in any lead. With strict rest the condition gradually improved, and by August 27th an *x*-ray examination was possible; this showed the enlargement of the cardiac outline typical of pericardial effusion, and at the same time the possibility of oesophageal obstruction was excluded.

Gradual improvement continued, but the amount of sputum was unchanged, and the physical signs over the left lung were variable; sometimes loud rhonchi could be heard, and at others the breath sounds were inaudible. At the end of September a small pleural effusion appeared at the left base. The temperature remained between 100° and 101° in the evening. On October 31st a left artificial pneumothorax was induced, and was followed by considerable improvement in the general condition, cough, and sputum. At present the patient is afebrile, up most of the day, and doing short walks; the daily sputum varies between one drachm and five ounces, the stridor has disappeared, and the breathing is easier than it has been for two years. A few tubercle bacilli are still present.

The most interesting feature of this case is the occurrence of precordial pain and pericardial effusion in a patient suffering from a form of tuberculosis unusual in that it produced pressure symptoms on the main air passages to such an extent that the presence of a neoplasm was suspected. Although infarction of the heart is quite a possible diagnosis, the presence of a tuberculous focus causing pressure in the near vicinity makes it seem more probable that the sudden onset of severe symptoms was due to the discharge of tuberculous material into the pericardial sac. In this connexion it would be interesting to hear if the authors of the previous paper were able to find any evidence of disease in the neighbourhood of the pericardium.—I am, etc.,

ANDREW MORLAND, M.D., M.R.C.P.,
Resident Physician, Mundesley Sanatorium.

May 15th.

PITUITRIN AND OBSTETRIC SHOCK

SIR,—In the *Journal* of May 16th (p. 837) Professor Miles Phillips records in detail a case of collapse occurring soon after the end of the second stage of labour and culminating in sudden death within twenty-four hours, and states that, no cause for the condition being discovered, the ultimate diagnosis was death from emotional shock. May I suggest that, in this and similar cases, the possibility of death being due to an idiosyncrasy to pituitrin should not be overlooked? I had occasion, about the same year (1925), to see a case which closely resembles that described by Professor Phillips.

A primipara, aged 29, after being fully twenty-four hours in labour, delivered herself without the aid of instruments at 11.20 p.m. She had been given 3 c.cm. of pituitrin, as follows: 1 c.cm. at 5 p.m., 1 c.cm. at 8 p.m., and 1 c.cm. at 10.30 p.m. The child did not survive, despite every care, though it drew a deep breath at long intervals for nearly two hours. At 11.45 p.m. the mother's pulse was scarcely perceptible at the wrist and 120 per minute in the femoral artery. The mother felt quite well, and continued to feel well till about 1 a.m. Despite warmth and salines her pulse did not improve. The uterus was nearly as high as the umbilicus, contracted occasionally, and there was no sign of haemorrhage or rupture. The placenta lay *in utero*, and was not interfered with. The patient was not restless. From 1 a.m. she gradually sank, and died at 3 a.m. Death was, apparently with justification, attributed to pituitrin. The same preparation, I was credibly informed, had been used freely in many previous cases without ill effect.

This case very closely resembles that described by Professor Phillips. It is true that in his case 1/2 c.cm. only of pituitrin was given; but pituitrin used to vary notably in strength. In the report of the Medical Research Council in December, 1922, it was shown that commercial preparations varied so greatly that the most potent may have eighty times the strength of the least potent, and vary marked variations both in oxytocic and pressor effects occurred in extracts described by the manufacturers as physiologically standardized. Also, the question of idiosyncrasy cannot be ruled out. In the current edition of the *Medical Annual*, Professor Beckwith Whitehouse, in the article on labour and its complications, quotes A. M. Mendenhall as sounding a timely note of warning regarding the use of pituitary extract. Mendenhall states that in actual clinical practice the effects of the same dose and of the same preparation often differ widely in patients under similar conditions; and that, furthermore, once started, the effect must continue, as no satisfactory antidote to pituitary extract is at present known.—I am, etc.,

Bradford, May 22nd. PETER MCEWAN.

SPINAL ANAESTHESIA

SIR,—In thanking Mr. Basil Hughes for his appreciative letter in last week's issue, may I say that it has become my practice to reserve the 3 c.cm. dose for cases demanding increased duration of anaesthesia. I depend only on upward table-tilting to extend the anaesthesia to the higher abdomen, and use the standard 2 c.cm. dose.

May not the dose in these cases literally be a vital point? For to obtain upper abdominal anaesthesia one depends on a rising tide of spinocain round the spinal nerves. There is obviously a high-water mark beyond which the tide cannot safely rise, and it is not only the rate of flow but also the volume of the rising tide that can harm the patient. Skill in administration depends on arresting the tide at the critical moment. Therefore it is among these upper abdominal cases the fatalities of spinal anaesthesia will chiefly occur, and, other things being equal, then the smaller the dose which is adequate the less the risk, and the larger the dose used the more perfect the precision required to control it.

It was largely thanks to a conversation with Professor Burgess of Manchester that I, too, embarked on spinocain anaesthesia.—I am, etc.,

Clifton, Bristol, May 25th. A. WILFRID ADAMS.

KONDOLÉON'S OPERATION

SIR,—Mr. J. Ewart Schofield's views on the Kondoléon operation in your issue of May 9th (p. 795) should not be allowed to go unchallenged. This operation, based on the work of Sappey (1874) on the lymphatics, was brilliantly conceived. It aimed at the removal of the dense deep fascia which was obstructing the flow of lymph. That in some cases the result was not permanent was shown by A. L. Gregg to be due to re-formation of this thickened fascia.[1] From the photographs, Mr. D. J. Harries's very successful case (*British Medical Journal*, December 27th, 1930, p. 1079) was one of true elephantiasis, giving a history of tuberculous disease and infection. A survey of some ninety cases recorded in the literature as elephantiasis showed that a very large proportion proved to be only oedema from lymphatic or venous obstruction. Hutchinson's definition is "a condition resulting from solid oedema and more or less resembling the appearance

[1] A. P. Bertwistle and A. L. Gregg: *Brit. Journ. Surg.*, 1928, xvi, No. 62.

of an elephant's limb." The outstanding feature of elephantiasis is chronic inflammation. Is it not possible that Mr. Schofield's was a case of lymphatic obstruction or thrombosis of the femoral vein and the tibial venae comites? In such cases where "the deep fascia was not easily defined" the operation could hardly be expected to give relief.—I am, etc.,

London, W., May 20th. A. P. BERTWISTLE.

EXAMINATION OF MOTORISTS CHARGED WITH DRUNKENNESS

SIR,—Is it not time the British Medical Association took steps to put a stop to the farce of a medical man being called in to say whether or not an individual who is obviously drunk and incapable is in a fit state to drive a motor car? The other day, at Cambridge, a man was found lying insensible over the steering-wheel of his car, which was on the pavement, and there were no tyres on the rear wheels. The police apparently had no doubt as to what was the matter with him, but, in order to satisfy the law, two medical men had to be got out of bed between 2 and 3 a.m. to say whether or not the man was drunk!

If the law insists on requiring a doctor to state the obvious, and regards his opinion as expert evidence, which it apparently does, the fee should at least be somewhere in keeping with the nature of the services rendered. I am fortunate in having so far escaped being called to such a case, and it was only to-day that I learned—to my amazement—that the usual fee is 5s. by day and 7s. 6d. during the night. I submit that the latter is not even sufficient as compensation for having had a much-needed night's rest ruined by a drunken reveller, let alone paying for the expert opinion. There are very few people these days who can afford the luxury of indulging in alcohol to the extent of placing their sobriety in question, and those who are in the privileged position of being able to do so can surely afford to pay the doctor a guinea by day, or two guineas by night, for services which may be the means of saving them from being sent to prison.—I am, etc.,

Melton, Suffolk, May 23rd. W. BROOKS KEITH, M.D.

Medico-Legal

ALLEGATION OF NEGLIGENCE AGAINST SURGEON WITHDRAWN

On May 11th, before Mr. Justice McCardie and a special jury, who were prepared to re-try the action, it was announced that a settlement had been reached in the case of Moore and Wife *v.* Ligat, which had previously come before Mr. Justice Horridge and a special jury, the jury disagreeing after a six days' hearing. The settlement was on the basis of an *ex gratia* payment, with the withdrawal of all allegations against the defendant.

Mr. H. H. Joy, K.C., and Mr. F. W. Wallace appeared at both courts as counsel for plaintiffs, and Mr. Roland Oliver, K.C., and Mr. H. C. Dickens for defendant. The defence was instructed by Messrs. Hempsons, acting on behalf of the Medical Defence Union.

In this case it was alleged that the defendant, Mr. David Ligat, F.R.C.S., had performed an operation on Mrs. Moore so negligently and unskilfully that the sight of her left eye had been destroyed, with the result that she could not carry on her occupation as a dressmaker. It appeared that some time before June, 1927, Mrs. Moore attended the out-patient department of the Buchanan Hospital, St. Leonards, for deflected septum and polypi. On examination by Mr. Ligat, surgeon in charge of the ear, nose, and throat department of the hospital, both nostrils were found plugged with multiple polypi, and the infection was setting up retrobulbar neuritis. An operation was arranged, and was performed by Mr. Ligat. He began to operate on the right side, first removing the polypi and then the turbinate bone, and the ethmoidal cells were cleaned out. He then proceeded to operate on the left side, but, unfortunately, instead of the turbinate bone coming away at its root, the ethmoidal cells, owing to the progress of the disease, came away with the turbinate, leaving a free opening between the nasal and the orbital cavities. This condition, not infrequent in operations, was recognized at once, and the surgeon refrained from plugging the nose, so as to ensure free drainage for any bleeding which ensued. Shortly after the operation it was noticed that the left eye was swollen slightly, and by the time the surgeon arrived the patient complained of loss of sight in the eye, and it was clear that there had been extensive haemorrhage into the eye, due to the breaking down of the partition wall. The defendant did what he could to relieve the position, hoping that the sight would recover when the haemorrhage was absorbed, but owing either to pressure from the haemorrhage on the already diseased optic nerve, or else to a thrombosis which very possibly existed prior to the operation, Mrs. Moore never recovered the sight of the eye.

On behalf of the plaintiffs, negligence and lack of skill were alleged in that Mr. Ligat appeared to have severed or injured beyond remedy the left optic nerve, or the arteries or veins, or that he failed to use reasonable care and skill in operating on or near the orbital plate of the ethmoid bone, and by means of his instrument penetrated and removed part of the orbital wall. On behalf of the defendant it was urged that if he had not operated at once the patient would certainly have lost the sight of this eye, and possibly of both, and that there was also a danger of loss of life from meningitis. Mr. Ligat himself was of opinion that the loss of sight was due to haemorrhage, and this view was shared by Mr. J. F. O'Malley and Mr. Somerville Hastings, both of whom gave evidence on his behalf. Both these witnesses agreed that the breaking down of the partition—that is, the ethmoidal cells between the nasal and the orbital cavities—could not be avoided in these cases, though it was not usually attended with such dire results. Mr. M. H. Whiting, who also gave evidence for the defendant, considered that the loss of sight was due to thrombosis, but he also agreed that the accident, if it might be so termed, was unavoidable, and that the condition found was quite compatible with Mr. Ligat's account of the case. A good deal of conflicting evidence was given as to the circumstances of Mrs. Moore's admission to the hospital, and as to whether she had complained of failing eyesight before the operation, which she strongly denied having done.

As stated, the jury disagreed.

When the re-trial of the action was about to begin, Mr. Joy, for the plaintiffs, said that the jury would not be troubled with the case. He had advised Mrs. Moore to accept a sum which the defendant had offered—she would receive £75 clear—but this in no way involved any admission of negligence on the part of the defendant. It was an *ex gratia* payment, and accepted in that spirit. The allegations of negligence were all withdrawn. He believed the plaintiffs were well advised to take this course. The "accident" had resulted in loss of sight of one eye, but he hoped that the lady would be able to make good use of the remaining eye and resume her occupation.

Mr. Roland Oliver said that, as all the expenses were borne by the Medical Defence Union, this was, for the surgeon, not a matter of money in the least; he was there to defend his reputation. His reputation was now vindicated by the frank and generous admission of counsel on the other side. The action, had it been retried, would have been costly, and it was better that the defence should offer to make some monetary payment. The reputation of the surgeon he was defending was fully restored and untarnished.

Mr. Justice McCardie said that he felt sure the parties had been well advised. The complete withdrawal of any suggestion of negligence had doubtless achieved the object with which the defendant and the Medical Defence Union had contested the case. He assented with pleasure to the compromise whereby £75 was paid to Mrs. Moore, and all allegations of negligence against Mr. Ligat were completely withdrawn.

Obituary.

W. D. HALLIBURTON, M.D., D.Sc., F.R.C.P., LL.D., F.R.S.

Emeritus Professor of Physiology, King's College, University of London

The death of Professor Halliburton at the age of 70 takes from us one of the great figures in the science of medicine in the last forty years. He had gone on holiday to Cornwall, as was his wont, but illness overtook him, and he passed away after an operation in a nursing home in Exeter on May 21st. His death, however, was not altogether unexpected, for since his retirement from his chair at King's College he had been far from well, and although he took a lively interest in affairs until quite recently, it was evident to his friends that he was slowly fading. In a physical sense Halliburton was never a robust plant — indeed, his whole life was a conquest over infirmity, and few men would have succeeded, as he did, in making one almost forget that he never had the power of his right hand. And yet few men have led more useful lives or have earned the right to be numbered among those to whose vision the world owes much, for he was one of the first to recognize the importance of chemistry in medicine, and he is remembered as one of the founders of the science of biochemistry.

William Dobinson Halliburton was educated at University College School, and subsequently at University College, where, after holding the usual clinical appointments, he became Sharpey scholar, and graduated B.Sc. in 1879. In 1883, when he became M.R.C.S., he was appointed assistant in physiology in University College under Professor (now Sir Edward Sharpey) Schafer, in succession to McWilliam, who became professor of physiology in the University of Aberdeen. He obtained the M.D. degree in 1884, and the M.R.C.P. diploma in the following year, and was elected a Fellow of the Royal College of Physicians of London in 1892. On the retirement of Gerald Yeo in 1889, Halliburton was appointed to the chair of physiology at King's College at the early age of 29. For thirty-four years he was at King's College, and although the world knows him for the work which he did there in the interests of physiology, few know how much he did for the College, for he took a lion's share in its administration. He was for many years dean of the Faculty of Medical Science, and on the death of Principal Burrows he acted as chairman of the Professorial Board. He was a member of the College staff in its dark days, and the College was indeed fortunate in such times of stress that it should have had in a central position one whose worldly goods made him independent of the then meagre College emoluments, and who devoted himself so ably and so whole-heartedly to its welfare. Had he chosen he might have led a life of leisure, but Halliburton was not such a man, and to him more than to any other single man the Medical Faculty at King's College owes its very existence. He resigned from his chair in 1923 on account of ill-health, and was made Emeritus Professor by the University. It is a happy thought to realize that he lived to see his years and years of labour fructify, for since the war the Faculty which he nurtured has grown to proportions previously undreamed of; and now it is one of the largest in London. In 1928 he himself had the pleasure of opening the extensions to the Department of Physiology—extensions which to him had been but a land of promise into which he never entered; and during the last year, when his physical activities were very limited, no one was more interested in the further extensions now in progress.

At King's College Halliburton gathered round him a number of able investigators—Brodie, Locke, C. J. Martin, Rosenheim, Da Fano, to name but a few—and many men now most distinguished clinicians were his pupils. He came particularly in contact with Ferrier and Mott, and there is little doubt that in some part this association was responsible for his making a special study of the chemistry of nervous tissues. It is interesting to remark that it was his researches, and those of Rosenheim in his laboratory, which led to the discovery that cholesterol might contain as impurity ergosterol, in which we now know vitamin D is developed under the influence of ultra-violet light. In these researches there is an untapped mine of knowledge still to be drawn upon in the interests of medicine. His biochemical laboratory — improvised in a corridor, and the first in London—rapidly became the Mecca to which large numbers of young biochemists came for instruction and inspiration. His early work was largely in relation to the biochemistry of the proteins of muscle and blood. For this work he was made a Fellow of the Royal Society in 1891. In the nature of things many of his discoveries have passed from current knowledge, but they will ever stand as essential stepping-stones in the advance of knowledge of the subject. He did not, however, confine himself strictly to biochemistry. With W. E. Dixon he carried out researches on the cerebral circulation and the cerebro-spinal fluid. He was one of the founders of the Biochemical Society, of which he was the only honorary member.

As a writer the name of Halliburton is a household word in medicine, and as such he joins the immortals. His name was as well known abroad as at home. Not only was he a brilliant writer, but he was assiduous to a degree that in our time appears phenomenal, the more so when we remember that he did all his writing with his left hand. Undoubtedly his greatest work is his *Textbook of Chemical Physiology and Pathology*, a volume of some 900 pages published in 1891. It collected together for the first time all the known information on this subject, and even to-day it is still used as a book of reference. His best-known book is "Halliburton's *Physiology*," which for the last thirty years has been the vade-mecum of

the medical student. It was originally "Kirkes's" *Physiology*, but he made it more popular than it ever was before. During his authorship, which began in 1896, there were nineteen editions, and no fewer than 125,000 copies were published. It has twice been translated into Chinese. In addition, he published a vast number of scientific papers, of which his *Essentials of Chemical Physiology* is still widely used at home and abroad. Others include *The Chemical Side of Nervous Activity* (Croonian Lectures, Royal College of Physicians, 1901), *Biochemistry of Muscle and Nerve* (1904), and *Physiology and National Needs* (1919). In 1916 he was asked by the Physiological Society to take over the editorship of *Physiological Abstracts*, which the society had decided to inaugurate. During his editorship the journal became firmly established, and now it is a periodical of international importance. Halliburton had already shown his great facility at this kind of work in writing the physiological section of the annual report of the Chemical Society.

Much of the work which he undertook was of the thankless variety, and carried with it none of the glamour which leads to material reward, but few have done more than he to spread the gospel of British Physiology and British Biochemistry. No one was more pleased than he to see the Royal Society elect, for the first time in history, a biochemist to its presidential chair, the more so since its choice was his friend Sir Frederick Hopkins. The Universities of Aberdeen and Toronto honoured Halliburton with their LL.D.; he was a Fellow of King's College and of University College; member of Senate, University of London, 1900–3; member of Council, Royal Society, 1898–1900. As a speaker Halliburton in his heyday had few equals, and when it was necessary to find a physiologist who could delight a popular audience he was often selected for the task. It was indeed a tragedy that in his later years this should have been the faculty which was slowly taken from him. But frailty had already tested his great spirit, and he murmured not.

As a man Halliburton was one of the old school, who knew how to make up his mind and to carry a clear-cut decision to its conclusion. Yet he was ever lovable and approachable. He had, among his more intimate friends, a great sense of humour, and nothing he enjoyed more than a comic song, at which he would often laugh immoderately. His kindly attitude to his students was nowhere better to be seen than on the occasion of the presentation by his students on his retirement. His short speech did not begin in the usual way, but "Boys and girls," and everyone felt the pathos of the occasion when he knew he was saying good-bye for ever to the students he loved so well. They often asked his help, and none asked in vain. His house—Church Cottage, nestling beside Marylebone Parish Church—was well known to his many friends, for he was ever a generous entertainer, and in this he was assisted by his wife, now his widow, who in his later years has been his faithful and ever-present companion in his hour of need. Often the possibility of moving to a more convenient house was discussed, but more and more it became evident that it was his earnest desire to remain in the atmosphere which was filled with the memories of more energetic days. Gradually he began to lose the friends of his own time, and we all knew that he sadly missed his great companion Sir Frederick Mott. Now that his own chapter closes, well may we thank God that men such as Halliburton have lived and shown us how to live.

R. J. S. McDOWALL.

Professor Halliburton had been for many years a member of the British Medical Association. At the Annual Meeting in 1893 at Newcastle-on-Tyne he held office as vice-president of the Section of Anatomy and Physiology, and he was president of the Section of Physiology at Ipswich in 1900, and again at Toronto in 1906. For five consecutive years—from 1909 to 1914—he received scientific grants from the Association. Many contributions from his pen appeared at different times in the *British Medical Journal*, and his Oliver-Sharpey Lectures on "New facts in relation to the processes of nervous degeneration and regeneration" were published in these columns in 1907.

SEYMOUR TAYLOR, M.D., F.R.C.P.

Consulting Physician, West London Hospital

We regret to record the death, on May 20th, at his home in Wembley Park, of Dr. Seymour Taylor, who practised for many years as a consulting physician in London, and was well known in medical circles for his kindly, genial disposition.

Seymour Taylor was born at Derby in May, 1851, and studied medicine at St. Thomas's Hospital, where he won several prizes and acted as demonstrator of anatomy, and at the University of Aberdeen. He obtained the M.R.C.S. diploma in 1872, graduated M.B., C.M.Aberd. in 1877, and proceeded M.D. in 1881, in which year he became M.R.C.P.Lond. Securing election to the visiting medical staff of the West London Hospital, he served in turn as assistant physician, physician, and consulting physician. He was also for many years physician to the North London Hospital for Consumption. He had been an examiner in anatomy at Aberdeen University, and was examiner in medicine for the English Conjoint Board for four years. In 1900 he was elected a Fellow of the Royal College of Physicians of London. He had long been physician to the Equitable Assurance Company. He was a past-president of the West London Medico-Chirurgical Society, and at one time treasurer of the Medical Defence Union.

Dr. Seymour Taylor was the author of two books, an *Index of Medicine*, published in 1894, and a little work, *Health for the Middle-Aged*, which reached a third edition. He also contributed papers on clinical subjects to professional journals.

Dr. ALGERNON D. BRENCHLEY writes:

I should like to add my tribute as one who has enjoyed the privilege of Seymour Taylor's friendship for fifty-four years, during the whole of which he never uttered one single unkind word. We were fellow students, and took our degree at the same time. He afterwards became physician to the West London Hospital, and lived in Seymour Street, Portman Square, till he retired. He was an excellent physician, a very sound clinician, full of common sense, with broad views, of a sympathetic, confident, cheerful nature, with, at proper times, a humorous vein. He paid much attention to life assurance, and was most of his life on the staff of one of the oldest companies, who thought so highly of his services that they continued to pay his full salary for life after his retirement. During the war he served on many medical boards. In private life he was a man of great personality and character, staunch to his friends, of whom he had many. His interest in sport was great; he loved fishing, golf, and country life. He was a member of the Savage Club, and was always the best of company at dinners and public meetings; he loved a witty tale, and told many himself. He is survived by Mrs. Seymour Taylor, and his son, Captain S. Taylor, R.A., and his daughter, who is secretary of the British Legation in Lisbon. Many will miss him, but none more than the writer of this note.

We regret to announce the death of Dr. W. D. PATERSON of Murrayfield Avenue, Edinburgh, at the early age of 30. He graduated M.B., Ch.B. at Edinburgh in 1923, and in 1927 obtained the B.Sc. degree at Oxford. A colleague (W. F. H.) sends the following appreciation: Only those of us who knew him will realize the extent of the loss the medical profession, and those of the public who would, in the natural course of events, have come under his care, have suffered in the death of William Dallas Paterson at the outset of what must have been a brilliant career. Son of a physician who was beloved, I have heard on all sides, by his patients, he would, in his turn, have occupied a position as trusted adviser to his patients and friends. Paterson was a profound thinker, an earnest inquirer, and, above all, conscientious. During his university career he threw himself heart and soul into every subject in the curriculum, studying each for the time being as if it were to be his life-work; physiology perhaps interested him most. After graduation at Edinburgh he went to Leith Hospital, where he spent a year studying clinical medicine in its practical aspects; he brought to this study the mind of the true student—the keen desire to find the prime cause, to evaluate accurately the effects of his treatment—and a profound knowledge of the basic sciences, which, alas! most of us do not possess. It was during this year that I associated with him most and came to know his true worth. After Leith came Oxford, where he attended a course in human physiology, and later worked at the hospital. During this time Paterson worked on a portable instrument for recording graphically systolic and diastolic blood pressures and fluctuations therein. At the time of his death he had but recently returned from a sojourn in Canada, where, at the Royal Victoria Hospital, Montreal, he continued his work on the same apparatus with encouraging results. His death on the threshold of his career, after spending so many years fitting himself for it, is indeed a tragedy, the more unexpected because of his apparent good health. He was always energetic; a keen walker, and in athletics a runner of merit, having won the mile at his school, Edinburgh Academy.

We regret to record the death, on May 12th, of Dr. JOHN OWEN JONES of Holywell. After obtaining the diplomas of the Conjoint Board in Scotland in 1886, he was appointed surgeon to the Flintshire Dispensary and Holywell Cottage Hospital, and medical officer in charge of the Holywell Auxiliary Hospital. He was also certifying factory surgeon, surgeon, and examiner of the St. John Ambulance Association, and an approved lecturer of the Central Midwives Board. A prominent member of the British Medical Association, he served as chairman of the Denbigh and Flint Division in 1912–13. He was a justice of the peace, and an alderman of the Flintshire County Council, the retention of which dignity compelled him to resign his offices under the Poor Law, through the introduction of the new Local Government Act. He was, however, appointed a member of the Public Assistance Committee. Dr. Jones was a member of the Court of Governors of University College, Bangor. He took great interest in Welsh literature, and always kept himself abreast of new medical work. He was a Liberal in politics and an elder of his church. A hard worker and with a large experience, he was often able to give valued advice to his colleagues and medical neighbours, by whom he was highly esteemed. He died in his sleep on returning home to bed from a very early consultation about one of his old patients. He leaves a widow, four daughters, and one son, who is a member of the medical profession.

The following well-known foreign medical men have recently died: Professor KARL L. SCHAEFER of Berlin, an authority on the physiology and pathology of the ear, aged 74; Professor OTTO HUNTEMÜLLER, formerly director of the international health office in Jerusalem, aged 53; Dr. UBALDO FERNANDEZ, professor of clinical obstetrics and director of the Alvear Maternity Hospital at Buenos Aires, aged 55; and Dr. PAUL SIMON, formerly professor of pathology at Nancy, aged 73.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

At a congregation held on May 22nd the degrees of M.B. and B.Chir. were conferred on F. G. Wood-Smith.

John Lane Presentation

The presentation to John Lane, senior steward of the University Anatomical Department, will be made on Tuesday, June 2nd, at 5 p.m., in the Anatomy School. It will consist of a gold watch and chain, together with a cheque, a short address, and a list of the subscribers, whose presence will be welcome on the occasion.

UNIVERSITY OF LONDON

Sir Ernest Graham-Little, M.P., M.D., has been re-elected by Convocation a member of the Senate.

Dr. E. L. Kennaway has been appointed to the University Chair of Experimental Pathology at the Cancer Hospital (Free) from May 1st.

The title of Emeritus Professor of Experimental Pathology in the University has been conferred upon Sir Charles Martin, M.D., F.R.S., and that of Emeritus Professor of Biochemistry on Dr. Arthur Harden, F.R.S., on their retirement from the Lister Institute of Preventive Medicine.

The title of Professor has been conferred on Dr. C. R. Harington, F.R.S., in respect of the post held by him at University College Hospital Medical School.

The Dunn Exhibitions in Anatomy and Physiology for 1931 have been awarded to E. W. Bintcliffe of St. Bartholomew's Hospital Medical College, and to S. O. Aylett of King's College.

UNIVERSITY OF DURHAM

On the occasion of the Marquess of Londonderry's installation as Chancellor of Durham University, on May 20th, Lord Dawson of Penn, President of the Royal College of Physicians of London, received the honorary degree of D.C.L.

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

The House of Commons adjourned on May 22nd till June 2nd, and the House of Lords from May 21st till June 9th.

On May 20th the House of Commons considered the Representation of the People Bill on report, and decided, by a majority, that at a General Election no person should vote in more than one constituency. The Government refused to make an exception for the University elector.

The Architects Registration Bill, which has passed the Commons, was read a third time by the Lords on May 21st.

Silicosis and Asbestosis (Medical Fees) Regulations, dated May 18th, 1931, have been laid on the tables of both Houses.

The Housing (Rural Workers Amendment) Bill was read a third time by the House of Commons on May 21st.

On May 21st the Home Secretary told the House of Commons that, in view of the legislation to which Parliament was committed and the present state of business, the postponement of the Factories Bill to next session seemed inevitable. On the same day the Prime Minister said he could hold out no hope of time being found for discussion of the Nursing Profession (Wages and Hours) Bill.

Alcohol and Motorists

At the House of Commons, on May 20th, Mr. Herbert Morrison received a deputation of medical men, who came to advocate the issue by the Minister of Transport to all applicants for a driving licence of an "alcohol warning card" similar to those issued by police authorities in Berlin and in Ontario. The deputation was introduced by Mr. Somerville Hastings and Dr. Alfred Salter, and speeches were delivered

by Sir Arthur Newsholme and Dr. H. M. Vernon. These pointed out the effect of small doses of alcohol in delaying the nervous reactions of motorists. Mr. Morrison, in reply, agreed that even the moderate use of alcohol by motorists was undesirable, but said that the issue of such advice was not likely to be respected by the British temperament. The Road Traffic Act had given special attention to the matter.

Shortage of R.A.M.C. Officers

Replying to Dr. Fremantle on May 21st, Mr. PETHICK-LAWRENCE stated that the interdepartmental committee to inquire into the shortage of officers of the Royal Army Medical Corps had not yet been set up, but it was hoped to announce its composition and terms of reference in a few days. Dr. FREMANTLE asked whether consideration was being given to the fact that a great deal depended on the future career offered in civil life after these officers retired, and whether it was possible to include in the committee some representatives of the Civil Services which employed the services of medical officers. Mr. PETHICK-LAWRENCE asked for notice of these questions.

Numbers of Insane and Mental Defectives

Mr. GREENWOOD furnished, on May 21st, a table which showed that on January 1st, 1930, there were chargeable to the State 6,356 insane persons, comprising 909 criminals, 152 in naval or military hospitals, and 5,295 Service or ex-Service patients. On the same date 884 mentally deficient persons were in State institutions. The comparable totals for those chargeable to local authorities on January 1st, 1930, were: insane persons, 126,941 ; mentally deficient persons in institutions under order, 20,629 ; other such persons under Section 3 of the Act of 1913, 177 ; such persons under guardianship (1,559) and in " places of safety " (216) making a total of 22,581 mental defectives chargeable to local authorities.

National Insurance

Mr. GREENWOOD told Mr. Thomas Lewis, on May 21st, that £500,000 was in process of distribution to approved societies in respect of arrears in the contribution year ended July, 1929, owed by persons who would otherwise be subject to reduction or suspension of benefits. A similar sum for the year to July, 1930, would be distributed on receipt of returns from the societies.

Mr. GREENWOOD states that, according to the latest returns, 344 out of 6,784 approved societies and branches in England and Wales have deficiencies in their administration accounts.

Slum Clearance.—In reply to Mr. Charles Williams on May 14th, Mr. GREENWOOD announced that in England and Wales 70 authorities had declared 205 clearance areas containing some 7,500 houses and a population of approximately 39,000. He added that it was too soon for him to express either satisfaction or dissatisfaction with the progress made in slum clearance schemes.

Schools for Epileptics.—In a reply to Mr. Albery, on May 14th, Mr. LEES-SMITH said that six residential special schools for epileptic children, providing accommodation for 609 children, were certified by the Board of Education. None of these schools was in Kent, but most admitted children from any area. Some institutions made provision for children whose mental defect was combined with epilepsy. There was a shortage of accommodation for epileptic children, but the Board of Education offered a grant of 50 per cent. to any local authority or voluntary association establishing these schools, and he hoped an increase in accommodation would result.

Housing in Scotland.—Mr. WESTWOOD, replying on May 19th to Mr. Boothby, said that last year 11,056 State-aided houses were completed in Scotland. This year, up to March 31st, 1,911 houses had been completed.

Pensions.—On May 19th Sir H. CAYZER asked the Minister of Pensions, in cases where a retired regular officer applied for commutation of pension supported by an opinion of his medical practitioner that he was a fit case, sympathetically to consider recommending such a case to the Commutation Board for medical examination before a decision on the application was given. Mr. F. O. ROBERTS said any medical evidence as to his state of health which an officer might submit would always receive full consideration by the Ministry of Pensions.

Gland Grafting in Veterinary Practice.—Mr. SHORT told Mr. Freeman, on May 20th, that gland grafting on living animals had been performed by Mr. Male of Reading in the ordinary course of veterinary practice for the purpose of treatment of the patients. These were not experiments within the meaning of the Act, so that no licence was necessary, nor had the Home Office any jurisdiction in the matter.

Infant Mortality in Scotland.—Mr. WESTWOOD, Under Secretary for Scotland, told Miss Lee, on May 20th, that in 1930 the average infantile mortality rate for the whole of Scotland, excluding burghal areas, was 69 per 1,000 births. The highest rate was 89 per 1,000 in Dumbartonshire, and the lowest 23 per 1,000 in Bute.

Notes in Brief

The report of the Royal Commission on Labour in India is expected towards the end of June.

From January 1st to May 19th, 1931, 45 of the Royal Air Force personnel have been killed in aircraft accidents and 39 injured.

In March, 1931, 203,617 cwt. of skimmed and sweetened milk, condensed, were imported into the United Kingdom.

The Minister of Health cannot at present contemplate the introduction of legislation to amend the Blind Persons Act with a view to increasing their pensions.

Medical News

A garden party in aid of the educational work of the Royal Medical Benevolent Fund Guild will be held at the Royal Botanic Gardens, Regent's Park, N.W., on Tuesday, June 2nd, from 2.30 to 8.30. H.R.H. the Duchess of York (patroness of the Guild) has consented to be present. Particulars and tickets of admission may be had from the honorary treasurer, Mrs. E. D. D. Davis, 46, Harley Street, W.1. (Telephone, Langham 1178.)

The Cavendish Lecture before the West London Medico-Chirurgical Society will be delivered by Professor Julian Huxley at the Kensington Town Hall on Friday, June 5th, at 8.15 p.m. ; his subject is " Development in relation to heredity and evolution." A reception will be held from 7.45 p.m., and the annual conversazione will follow the lecture.

An open-air Chadwick Lecture on " Trees and man " will be given by Mr. T. F. Chipp, D.Sc., at the Chelsea Physic Garden, Swan Walk, S.W., on Thursday, June 4th, at 5 p.m. ; Sir William J. Collins will take the chair.

Founder's Day will be celebrated by Lord Mayor Treloar Cripples' Hospital and College at Alton, on Monday next, June 1st, when Admiral of the Fleet Sir Roger Keyes will open the Portsmouth Block, which contains the Fourth Destroyer Flotilla and Naval Memorial wards. Viscount Burnham will preside at the function, supported by the Lord Mayor of London, Admiral Sir Lionel Halsey, the Earl of Malmesbury (chairman of the Hampshire County Council), and the Lord Mayor of Portsmouth. Five sections of the new hospital are now completed.

At the inaugural meeting of the congress of the Royal Institute of Public Health, held in the University of Frankfort-on-Main on May 19th, the Harben gold medal of the institute was presented to Professor William Henry Welch of Johns Hopkins University, Baltimore, in recognition of his eminent services to public health. At the same meeting the Rector Magnificus presented to Sir William R. Smith the Ehrlich-Weigert medal of the Medical Faculty of the University of Frankfort. On May 20th, at the Rathaus, the Oberbürgermeister presented to the institute the medal of honour of the city in remembrance of this congress—the first to be held on German soil for nineteen years—and handed the medal to Sir Thomas Oliver, pro-vice-chancellor of the University of Durham, and chairman of council of the institute.

The president (Viscount D'Abernon) and council of the National Institute of Industrial Psychology will receive guests at the Institute, Aldwych House, on the evening of Monday, June 1st, and on the afternoon of Tuesday, June 2nd. Films bearing on the Institute's work will be shown, and a number of demonstrations will be given, illustrating, *inter alia*, the measurement of ventilation and lighting conditions, the influence of rhythm on motor activity, tests of colour discrimination, methods of vocational guidance, the psycho-galvanic reflex, and a test for motor driving.

A medical tour of Czechoslovakian spas is being arranged by the Pistany Spa Representation (38, Sackville Street, Piccadilly, W.1). The party will leave London for Ostend on the morning of August 24th, and will travel direct by sleeping car to Austria, where visits will be made to Linz and Vienna. Four days will then be spent at Pistany, three each at Luhacovice and at Prague, and the party will return via Nuremberg, reaching London on the evening of September 11th.

The president and council of the Harveian Society of London, in continuation of the society's centenary celebrations, will make a pilgrimage to the tomb of William Harvey in the parish church of Hempstead, in Essex, on Saturday, June 13th. The Bishop of Colchester will conduct a short service at twelve noon, when a silver patten, presented by the society, will be consecrated. On the return journey the party will be entertained to tea by Lady Lloyd, at Rolls Park, Chigwell, which was originally the home of William Harvey.

The University of London has added Stoke Park Colony, Stapleton, Bristol, to the list of institutions recognized for practice under Regulation 3 for the Diploma in Psychological Medicine for candidates offering mental deficiency as their special branch under Regulation 4.

The Very Rev. Garfield Hodder Williams, dean of Llandaff, who has been appointed to the deanery of Manchester, studied medicine at St. Bartholomew's Hospital and graduated M.B., B.S. of the University of London.

The third International Congress of Radiology will be held at the Sorbonne, Paris, from July 26th to 31st, with Mme Curie as president of honour and Dr. Antoine Béclère as president. More than 300 communications have been announced. The congress will be divided into six sections: (1) radio-diagnosis; (2) radiotherapy and radium therapy; (3) radio-physics; (4) radio-biology; (5) electrology; (6) natural and artificial heliotherapy. Further information can be obtained from the general secretary, Dr. Ledoux-Lebard, 122, Rue La Boëtie, Paris, 8e.

The sixth International Congress of Industrial Accidents and Diseases will be held at Geneva from August 3rd to 8th, when special attention will be devoted to cutaneous affections in relation to occupation, the influence of previous health on the results of industrial accidents, sequels of traumatic wounds of the spine, trauma of blood vessels, reaction to toxic substances used in industry, diseases of cement and stone workers, and fatigue. Arrangements for the journey and for accommodation in Geneva are being made by Messrs. Thomas Cook and Son. Further information about the conference may be obtained from Mr. G. L. Perry, Industrial Welfare Society, 51, Palace Street, Westminster, S.W.1.

The second International Congress of Light Therapy will be held at Copenhagen from August 15th to 18th, 1932, under the presidency of Dr. Axel Reyn, chief physician to the Finsen Institute in that city. The main topics to be discussed are the part played by the skin pigmentation in the therapeutic uses of light; the way in which light baths act in tuberculosis; sunshine and climate in relation to public health administration; and the report of the international committee on ultra-violet light standardization. Any medical practitioner may attend the congress, and further particulars may be obtained from the general secretary, Dr. A. Kissmeyer, Finsens Lysinstitut, Copenhagen.

The report of the pathological laboratories of the City of London Hospital for Diseases of the Heart and Lungs for 1930 has been issued as a booklet. It contains a summary of the work performed, and reprints of various papers published by Dr. S. Roodhouse Gloyne, pathologist to the hospital during 1930. These laboratories were equipped by the Prudential Assurance Company.

The King has confirmed the appointment of Dr. Alexander H. B. Pearce, chief medical officer, to be a nominated member of the Legislative Council of the Colony of Fiji.

Dr. George Hargreaves has been appointed a nominated member of the Legislative Council of Jamaica, subject to His Majesty's pleasure.

Dr. Simon Flexner, director of the Research Laboratories of the Rockefeller Institute of New York, has been elected a corresponding member of the Académie des Sciences, and Professor Niessl von Mayendorf of Leipzig has been elected a corresponding member of the Société de Neurologie of Paris.

Only two cases of small-pox occurred in each of the years 1929 and 1930 in Germany, and all four recovered, as compared with 11,000 cases in England, with 30 deaths in 1929 and 9,000 cases with 22 deaths in the first half of 1930.

The increased incidence of pellagra of recent years in the United States is shown by the fact that while in 1924 there were only 2.5 cases per 10,000 inhabitants, in 1928 there were 5.7, and in 1929 5.5.

In 1930 six fresh cases of leprosy were notified in Germany. Infection had taken place abroad, in most cases in South America. Ten cases remained under treatment at the end of the year.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are *MUSEUM* 9861, 9862, 9863, and 9864 (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Medisecra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS

Erythromelalgia

Dr. J. AICKIN writes: I have a case at present of erythromelalgia in a woman, which is very resistant to treatment along the ordinary lines. She has had bromides and liq. trinitrini, and sedative applications to the affected tee. I wonder if any of your readers have had a similar case, and what line of treatment they found useful.

Malnutrition with Ammoniacal Urine

"CARNE" asks for advice about the treatment of the following case: A child, aged 3 years, born six weeks prematurely, fails to put on weight, though growing, urine always strongly ammoniacal, and testicles very incompletely descended.

Income Tax

Motor Car Transactions

"A. R." bought a 12 h.p. car for £425 in 1922 and sold it in 1930 for £40, when he bought a 16 h.p. car for £400. *He has made no claim for depreciation.*

*** He can claim as a professional expense of the year 1930 £400 − £40 = £360. The net loss of £25 provides no claim, though he would have received an allowance for it if he had claimed depreciation. Presumably the new car is a better one than the original car, but the income tax authorities are not likely to raise that point, as its cost is less than that of the car displaced.

"A. E. B." bought a car in March, 1926, for £225 and sold it in April, 1931, for £15, buying another car (second-hand apparently) for £135. What allowance is he entitled to? He has not claimed depreciation.

*** Depreciation should undoubtedly have been claimed; the omission to make such claims nearly always involves loss sooner or later. The renewal claim which "A. E. B." can make is for £120 only—the amount of his actual out-of-pocket expenditure—and as the expense was incurred *during the financial year 1931-32 it will not affect his* liability for that year, but for 1932-33.

"F. Z. O." bought a car in 1907 for £550, and since then has had numerous cars, but this year bought one for £515, the majority of the other cars having cost about £350 each. The maximum allowance offered by the income tax authorities is based on a replacement value of £400.

*** We are not aware that the case is covered by direct judicial authority, but we fear that the income tax inspector is right. The cardinal principle is that the cost of improving, as distinct from maintaining, the equipment must be regarded as capital outlay, and it is presumably beyond argument that the present £515 car is a more powerful and better car than the original one at £550. When the price of cars rose during the war the cost of replacement was allowed though it exceeded the cost of the car replaced. "F. Z. O." was in the converse position, apparently, when he was buying his cars at £350, and now has to bear the whole cost of the "improvement."

New Partner: Cash Basis

"P. N. B."—A has been in general practice since 1917, and has throughout been assessed on the cash basis. In 1925 he took B into partnership on a one-third basis, B purchasing one-third of the agreed value of book debts. The income tax inspector now claims that the value of all outstanding debts should be ascertained and tax paid on that amount.

*** We cannot see the justification for such a request. If the gross earnings of the practice are increasing so that the amount of the cash receipts is lagging behind the real earnings there is something to be said for departing from the cash basis and in future basing the assessment on the value of each year's bookings, but not for claiming tax on the amount of the value of the outstanding debts as an additional liability. The whole principle of the "cash receipts" basis is that it yields, taking one year with another, the same gross assessment as the "value of bookings basis"; and as the share of debts which B purchased has, in fact, been included in the cash receipts for assessment purposes, there appears to be no ground for the action suggested. In any case, for which year does the inspector suggest that the supplementary assessment should be made?

Alteration of Previous Year's Assessment

"X X" left his former practice as from November 15th, 1929, and since then has been in practice elsewhere. For the final period his old practice was comparatively unprofitable, "but 1928-29 was a good one financially." The assessment for that year was a small one, and the income tax authorities are now seeking to alter it. Is this correct?

*** Yes; under fairly recent legislation, where a practice changes hands, the assessment on the former practitioner for the year in which the change takes place, *and the previous year* can be altered to the amounts of the actual profits of those years. It is apparently under that provision that the authorities propose to alter the assessment for the year ending April 5th, 1929, to the amount of the profits of the practice for that year.

Allowance of Cost of Subscriptions

"A. T." has been informed by the inspector of taxes that the cost of his subscriptions to the British Medical Association, Royal Sanitary Institute, Society of Medical Officers of Health, and other bodies cannot be allowed as deductions from his income; the authority cited is the decision in Simpson *v.* Tate.

*** Presumably the income in question is the salary of an office or employment, and in that case the inspector's view is legally correct, unless it was an express or implied condition of the appointment that "A. T." should be a member of the societies, etc., specified. This results from the very strict rule applicable to Schedule E. Similar expenses would be allowed if incurred in connexion with general practice the profits of which are assessable under Schedule D.

LETTERS, NOTES, ETC.

Nitrous Oxide Mixtures

Dr. BELLAMY GARDNER (London, N.W.) writes: I consider that a specific name of an attractive character has long been required for nitrous oxide and its mixture with oxygen and small percentages of carbon dioxide. If we look carefully at its chemical composition, we find that only those elements which are present in the atmosphere are contained in it. I suggest, therefore, that the word *aeris*—that is, of air—would be a scientific and euphonious designation for this most acceptable and beneficent anaesthetic. The word "gas" is a misleading generic term, associated in the public mind with various unpleasant and irrespirable gases.

Hypnosis with Spinal Anaesthesia

Dr. E. L. HOPEWELL-ASH (London, W.) writes: In his remarkably interesting study of 250 cases of spinal anaesthesia (*British Medical Journal*, May 9th) Mr. Wilfrid Adams makes an important point when he notes, "Sometimes the patient's mind is not at ease, and to avoid psychic shock requires the most thoughtful care." It is my view that in the induction of definite hypnosis he will find just the adjunct required to complete his technique. Application of a few simple rules will suffice to bring about a mental state characterized by calm and confidence, which can be reinforced by suggestion to an unlimited extent.

Varicose Ulcers

"M. M." writes: I have read the letters in the *British Medical Journal* about varicose ulcers. I wonder if anyone has tried what I have seen somewhere described as an ointment bath. My plan is: A piece of boric lint the size and shape of the ulcer has spread on one side a fairly good supply of boric ointment made with yellow vaseline. Over this is a larger piece of lint put on dry, and the whole is kept in position by inch-wide strips of Mead's plaster going fully around the leg well above and below the ulcer. If I find the plaster irritates the skin I put gauze under it. This dressing is changed weekly, and the patient allowed to go about. The results are really very satisfactory.

Medical Golf

The Divisional stage in the Treasurer's Cup golf competition was played by members of the Dumbartonshire Division at Cardross Golf Course, by the courtesy of the council of the club, on May 13th. In spite of very uncertain weather there was a fair turn-out, and the afternoon proved very enjoyable to those taking part. The result of the game, which was played under medal conditions, members playing from their club handicap, was as follows: Winner: Major M. Purvis, I.M.S. (ret.), Dunbeg, Helensburgh (88 − 11 = 77 net). Runner-up: Dr. L. Crombie, Dunollie, Dalmuir (87 − 10 = 77 net). Major Purvis's score was 42 for the return half, and Dr. Crombie's 46, so that the former was declared the winner. Dr. A. D. Downes, Helensburgh, who was third, participated with the winner and runner-up in the sweepstake.

Vacancies

Notifications of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 41, 42, 43, 44, 45, 48, 49, and 50 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 46 and 47.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 215.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

509 The Blood in Delirium Tremens

E. TOULOUSE, A. COURTOIS, and RUSSELL (*Ann. Méd.-psych.*, February, 1931, p. 124) examined the blood in the course of delirium tremens with the following results. The amount of urea, sugar, and cholesterin is usually normal, or only slightly increased, at the onset of the mental symptoms. During the course of the attack there is a retention of these bodies chiefly affecting the urea. After the attack the azotaemia does not return to the normal for several days. The bile pigments were always found distinctly increased on admission of the patients, but rapidly became eliminated, and their amount soon fell after the attack. This fact, correlated with the changes found in the urine (albuminuria, glycosuria, and abundant urobilinuria), appeared to indicate an initial insufficiency of the liver. In fatal cases the azotaemia rose while the attack lasted, but usually at the time of death the amount of urea did not reach 2 grams per mille. As this figure may be exceeded in non-fatal cases, the prognostic value of this azotaemia is very slight.

510 Pulmonary Embolisms in Developing Myocardial Infarct

P. LÉCHELLE and R. BOUCOMONT (*Presse Méd.*, March 18th, 1931, p. 399) record the case of a man, aged 52, who was seen first in August, 1929, suffering from severe precordial pain, the sputum being typical of acute pulmonary oedema. These cardiac attacks had occurred for several years, and an *x*-ray examination two years earlier had revealed hypertrophy of the left ventricle and dilatation of the aorta. The apex beat was in the sixth space, outside the nipple line; there was a mitral systolic murmur, gallop rhythm, pericardial friction at the base, and a pulse rate of 120. There were moist rales at both pulmonary bases. The liver was slightly enlarged and tender, and the temperature 100.8° F. After 500 c.cm. of blood had been withdrawn, an intravenous injection of 0.25 mg. of ouabain was given, and repeated the same evening; 2 ampoules of pantopon were injected. The patient improved, and on the fifth day pain and pericardial friction had disappeared. Ouabain was continued, but gardenal was substituted for the opium. On the seventh day there was a severe attack of pain at the right base, with orthopnoea, and the appearance of a murmur accompanied dry crepitant rales in this region. The temperature rose to 101°, and on the ninth day there was blood-stained sputum. A pleural effusion ensued. All signs at the right pulmonary base disappeared in a few days, but on the fourteenth day there was a similar attack localized under the left armpit. Blood-stained sputum reappeared for a few days. During all this period there were increasing signs of cardiac insufficiency and dilatation of the right heart. Ouabain was continued for twenty-six days without any sign of intolerance. On the twentieth day digitaline was exhibited. Signs of the two pulmonary infarcts disappeared in five weeks. The blood pressure ranged between 165/90 and 135/80. Ouabain by the mouth and gardenal were continued. The patient returned to his ordinary occupation, but died from an acute attack in February, 1930.

511 Angina Pectoris

F. C. WOOD, C. C. WOLFERTH, and MARY M. LIVEZEY (*Arch. Int. Med.*, March, 1931, p. 339) studied the clinical and electrocardiographic phenomena in thirty cases of angina pectoris before, during, and after the attacks; they also compared them with the effects of experimental temporary coronary occlusion. Transient ventricular complex changes were noted in fifteen during the pain; neither exercise nor the accompanying alterations in blood pressure and pulse rate were altogether responsible for these changes. The remaining fifteen patients showed no such electrocardiographic changes, and the severity of the pain did not appear to be the main determining factor of their presence or absence. That the absence of electrocardiographic changes seen in 50 per cent. of the cases does not prove that temporary myocardial ischaemia did not occur was borne out by the result of experimental occlusion of a coronary artery; the production of alterations in the cardiac appearance and action was frequently unaccompanied by any electrocardiographic change. The relief of pain by nitrites did not always appear to be dependent upon the lowered blood pressure caused thereby, since the fall in blood pressure within fifteen seconds after inhaling amyl nitrite usually rebounds to from 10 to 20 mm. above its original level after inhalation stops. The prognostic value of these electrocardiographic changes during attacks cannot yet be determined; although no untoward occurrences arose, the procedure cannot be recommended owing to the danger attending the induction of anginal attacks. Temporary interference with part of the coronary circulation in animals produced changes in the electrocardiogram somewhat analogous to those seen during an attack of angina. The authors add that these studies support the hypothesis that the majority of true anginal attacks are associated with a localized circulatory disturbance in the heart, though they do not preclude the possibility that other mechanisms may produce precordial pain.

512 Syphilis without Chancre

M. MANSOUR (*Thèse de Paris*, 1931, No. 21), who records sixteen illustrative cases, states that syphilis may occur without an initial chancre; it is then manifested either by a glandular reaction or by the appearance of secondary or secundo-tertiary symptoms. With the exception of the congenital disease, this form of syphilis appears to be rare, and a careful examination should be made for the chancre or a scar in every suspected case of syphilis. In view of the undoubted possibility of transmission of syphilis from the donor to the recipient, special care should be taken to make sure of the donor's good health in transfusions of blood, and, except in extremely urgent cases, a complete clinical and serological examination of the donor should be undertaken. In the case of professional donors it is not sufficient for this examination to be made only once, but it should be repeated at frequent intervals, at least every month, and as near as possible to the date of transfusion.

513 Vaccinial Encephalitis

H. R. VIETS and S. WARREN (*New England Journ. Med.*, March 5th, 1931, p. 475) report three cases of this form of encephalitis; two patients died on the fourteenth day after vaccination. The earliest symptoms are headache, vomiting, and pyrexia, with a tendency to paralysis. In infants, in addition to these symptoms, convulsions are frequent. Consciousness is soon lost. The paralysis consists of weakness of the cranial nerves or of the extremities, and there is a considerable variation in the intensity from time to time. The Babinski response is sometimes obtained; as the disease progresses the deep reflexes disappear. Sphincter control is usually disordered, incontinence being a common finding. Trismus has occurred in many cases—a symptom which has led to errors in diagnosis. The spinal fluid pressure is often increased, and there may be present a few mononuclear and polynuclear cells; otherwise it is negative. Residual defect, as in poliomyelitis, is not usual, though in the case that recovered in this series "foot-drop" was present four months after the illness. Later manifestations, so frequent in encephalitis lethargica, have not been recorded. The mortality ranges from 35 to 50 per cent. The microscopical pathology is distinctive; the outstanding lesion is perivascular cellular infiltration, extending out into

the brain substance, and usually accompanied by demyelinization. The lesions tend to involve the white matter rather than the grey, but the more acute the case, the more even is the distribution. The lesions may be most intense in the region of the pons and the upper portion of the medulla.

514 Cutaneous Pigmentation and Health

As the result of an extensive study of the effects of heliotherapy, particularly in children, FR.-M. MESSERLI (*Rev. Méd. de la Suisse Romande*, March 10th, 1931, p. 137) states that cutaneous pigmentation is constant in helio- or actino-therapy, and as a rule individuals who pigment readily are in better health than those who do so with difficulty. This pigmentation, which is a special defensive property of the skin against injurious external agents, and is due to melanin in the deep layer of the Malpighian stratum, depends on the individual pigmentary reserve, the amount of haemoglobin, and the presence or absence of cachectic disease. Though seemingly not an important agent in causing cure, it gives useful indications as to the patient's general resistance and progress. Depigmentation depends on the same factors and, providing still clearer indications as to the results and permanency of the cure, is a guide to diagnosis, prognosis, and future treatment. In each individual there is a limit of pigmentation, ascertainable by a pigmentometer; when this has been reached further treatment by heliotherapy is useless. The power of pigmentation varies from year to year, but generally increases each year until the limit is reached. It has been noted that in certain diseases, such as tuberculosis, patients become pigmented much less markedly and lose their colour more rapidly. Messerli advises that, as a guide to diagnosis and treatment, a pigmentary curve of each subject under treatment be made by ascertaining weekly the rapidity and degree of pigmentation and depigmentation, and that the temperature be taken frequently, preferably every two hours.

515 Mental Symptoms of Hypoglycaemia

REINWEIN (*Deut. med. Woch.*, April 3rd, 1931, p. 571) draws attention to the fact that mental symptoms, such as disorientation, uncontrolled laughter, and peculiar behaviour, may be due to hypoglycaemia; they are not necessarily preceded by the usual complaint of hunger, sweating, or weakness. In other cases, epileptiform attacks, or symptoms resembling apoplexy, occur. Several illustrative cases are recorded of diabetic patients receiving relatively large doses of insulin and, owing to some upsetting factor such as diarrhoea, vomiting, or excessive muscular work, suddenly developing hypoglycaemia with mental symptoms. The diagnosis is usually easy so long as the existence of diabetes is borne in mind. In some cases large amounts of sugar must be given, so that failure to relieve the symptoms immediately by injecting glucose does not disprove the diagnosis.

516 Meningococcal Meningitis

V. CANTALAMESSA (*La Pediatria*, March 1st, 1931, p. 233), as the result of a study of 42 cases of meningococcal meningitis occurring in infants, concludes that although its insidious onset makes early diagnosis difficult, suggestive symptoms are the quick pulse and respiration without fever; the hyperaesthesia, restlessness, and vomiting; the tense fontanelle and neck rigidity (in rare cases flaccidity occurs rather than rigidity); and the convulsions, wasting, and leucocytosis. There is usually intermittent irregular fever; in four cases the course of the disease was apyrexial. In every case meningococci were found in the spinal fluid. In some cases blockage occurred in the cerebro-spinal channels, causing secondary hydrocephalus in three cases. The mortality was high (75 per cent.) in spite of serum injections into the spinal canal and ventricles. The duration of the disease varied from a minimum of three or four days up to fourteen or fifteen weeks. In 20 of the author's cases there was a sudden onset; of these only 3 recovered, while of the 22 with slow onset 7 recovered. Moderate enlargement of the spleen was noted in several instances.

Surgery

517 Acute Dilatation of the Stomach

J. MORROW (*Minnesota Med.*, March, 1931, p. 218) describes ten cases of post-operative dilatation of the stomach; in none of them was the stomach operated on, and two were fatal. The probable etiology, he states, is, firstly, gastric relaxation due to reflex loss of tone, and secondly, some added and perhaps chance mechanical obstruction. An early symptom is constant distress in the left upper quadrant of the abdomen, unrelieved by enema. A tympanitic note may be heard over a large area, and immediate relief follows the passage of the stomach tube. A later stage is characterized by the accumulation of very large quantities of water in the stomach, toxic symptoms, signs of dehydration, and collapse. Gastric lavage every four hours is advised, aided by elevation of the pelvis, or even the adoption of the knee-elbow position, if practicable, and by small doses of pituitrin. For cases with toxaemia intravenous injections of 500 c.cm. of normal saline are advocated. The duodenal tube and continuous gastric siphonage were both tried with comparatively poor results.

518 Spondylitis Deformans

According to S. KLEINBERG (*Arch. of Surg.*, March, 1931, p. 485) the progressive deformity of spondylitis deformans may be checked by an early diagnosis and by the immediate institution of proper treatment. This chronic disease of the back is characterized by increasing stiffness and deformity of the spine; backache; pains in the head, chest, or extremities; and impairment of the general health. Three etiological types may be distinguished: one which is part of a general metabolic disturbance, the traumatic, and one associated with some infection. The chief pathological change, common to all varieties, is a chronic, progressive, ossifying periostitis of the spine which leads to ankylosis of the vertebral and costo-vertebral joints. This process may be limited, but it usually involves the entire spine. Treatment, both general and local, to be effective must be instituted before the spinal ankylosis is complete. Local measures consist in continuous treatment on a convex frame, supplemented by physiotherapy, stretching of the back, and voluntary corrective exercises. After correction of the deformity, the back must be supported in a spinal brace for a long period. Four cases, representative of the different types, are recorded.

519 Obliteration of the Common Bile Duct

R. L. T. GRANT and L. O. BETTS (*Med. Journ. of Australia*, February 14th, 1931, p. 200) report the case of a boy, aged 8 years, with a history of jaundice of three months' duration. The skin, sclerae, urine, and faeces presented the usual appearances. The liver dullness extended just below the costal margin. The Wassermann test was negative. The urine contained bile but no urobilinogen. Van den Bergh's test was positive; the bilirubin was increased to 4 units. The Mantoux and Casoni tests were negative. On cholecystography no shadow of the gall-bladder was seen. The levulose tolerance test showed slight but definite impairment of liver function. No bile was demonstrated in the contents of the duodenum, aspirated through a tube passed by the mouth. All tests showed complete obstructive jaundice. The boy's condition had deteriorated materially during the month of these investigations, and an exploratory operation was performed; all that could be found representing the common bile duct was a definite fibrous band in which no lumen could be discovered. The gall-bladder was not distended; it was opened and about 8 c.cm. of concentrated bile were evacuated. As the cystic duct was apparently functioning a cholecyst-duodenostomy was performed. On the duodenum being opened, a little bile-stained fluid was seen, but the boy's condition precluded further investigation. Convalescence was satisfactory, the jaundice disappearing completely in five weeks.

520 **Exophthalmic Goitre**

B. DESPLAS (*Bull. et Mém. Soc. Nat. de Chir.*, March 14th, 1931, p. 360) reports eleven goitre patients, of whom eight were suffering from Basedow's disease and three from grave toxic goitre. There was only one death in the series; this occurred thirty-six hours after operation in a patient who had a very rapid and irregular pulse with diarrhoea and cold sweats. It was the only case in which the general anaesthetic used was ether; although the patient was in a very poor condition, the author regrets that local anaesthesia was not employed, since it proved so successful in the other cases. A two-stage operation was found to be the most satisfactory, the first stage consisting of ligature of the superior thyroid vessels combined with a sympathectomy, the second stage being hemithyroidectomy or enucleation of the adenomata when present. In certain cases where the patient is in a grave condition, ligature of the thyroid vessels only is carried out, and this has given relief. Careful pre-operative measures, such as complete rest, a milk diet, and digitalis and iodine treatment, are of great benefit. In cases which show an intolerance for iodine this must be omitted. One case treated by radiotherapy developed *x*-ray dermatitis with ulceration without deriving any benefit, although a subsequent hemithyroidectomy was most successful. The after-results in the ten patients who recovered were very satisfactory, and after an interval ranging from two to eleven years all but one were in good health. The essential syndrome had disappeared, and there was no more tachycardia or pulse irregularity; the patients had gained in weight, and were able to lead normal lives.

521 **Results of Extrapleural Thoracoplasty**

As indications for thoracoplasty in pulmonary tuberculosis, O. SCHEDTLER (*Deut. med. Woch.*, March 20th, 1931, p. 491) enumerates: (1) all unilateral cavernous cases; (2) bilateral cavernous cases if the state of the opposite lung is not too advanced, and is not progressing (at least two months' observation); (3) incomplete pneumothorax with cavernous or adherent upper lobes; (4) the same with serous or purulent exudate; (5) residual cavities after pyo-pneumothorax, if conservative treatment fails; (6) dangerous haemoptysis, if pneumothorax is impossible or unsuccessful; and (7) severe fibrosis with symptoms due to cardiac displacement. The operation of total thoracoplasty is performed as rapidly as possible under local anaesthesia in one stage, or more commonly two. In 320 consecutive cases operated on in Ziegler's clinic prior to October, 1929, the total mortality within eight weeks of operation was 5.3 per cent., but in uncomplicated unilateral cases 3.3 per cent. Of the first 200 thoracoplasties performed 64.5 per cent. of the patients are alive and 2 per cent. untraced; 43.5 per cent. of the 200 are considered healed—that is, they are capable of light or moderate work without symptoms, and are sputum-negative. Another 19.5 per cent. improved. In the author's opinion thoracoplasty is an effective method of combating severe cases of pulmonary tuberculosis which at present is not sufficiently recognized and used. If the correct indications are observed, and careful pre- and post-operative treatment is combined with exact technique, the procedure is comparatively safe.

522 **Osteoma of the Humerus**

G. FORNI (*Chir. d. Org. di Movimento*, February, 1931, p. 497) reports the case of a boy, aged 10, who sustained a slight injury to his left arm in September, 1927. In the following November some swelling of the arm was noted; periostitis was diagnosed, and treatment appropriate to that condition was applied, but no improvement followed. In March, 1929, the arm was *x*-rayed, and a diagnosis of osteosarcoma was made. The parents refused amputation. Since the growth was very slow, and there were no signs of secondary deposit, a part of the tibia with its periosteum was excised and transplanted into the gap made by complete resection of the growth in the humerus. Convalescence was satisfactory, and after nearly two years the boy remains well, has a useful arm, and shows no signs of recurrence.

Therapeutics

523 **Serum Treatment of Erysipelas**

F. EISELBERG (*Wien. klin. Woch.*, February 27th, 1931, p. 290) records his observations on 43 cases of erysipelas treated by subcutaneous injections of polyvalent anti-streptococcal serum. The cases in which the serum was used were characterized by a progressive character, high temperature, and toxic symptoms. The initial doses were 20–40 c.cm., and the other injections were repeated until a total of 80–100 c.cm. in all had been given. The results were as follows: in half the cases there was no obvious effect on the temperature curve, while in the other half the fall of temperature was only transient. In most of the cases, however, there was a rapid relief of subjective symptoms, even when the serum was given after the fourth day. Six of the 43 cases ended fatally, death being due in one instance to sinus thrombosis and meningitis, and in the other five to severe septicaemia which was in no way affected by the serum.

524 **Treatment of Chronic Arthritis**

PODOLSKY (*Med. Journ. and Record*, March 18th, 1931, p. 270) states that benefit is obtained in chronic arthritis by associating the magnesium salt of phenylcinchoninic acid with such compounds as magnesium oxide. The ethyl ester of para-methyl-phenylcinchoninic acid was also used effectively in this way. Podolsky reports a series of thirty arthritic patients dealt with on these lines, and details are given of the clinical results, improvement ensuing in some cases which had proved absolutely resistant to other forms of treatment. The doses of the synergistic magnesium compounds employed were minimal. No gastro-intestinal disturbance or nausea was observed, and there were no manifestations of any other form of toxicity. Pain not easily controlled by other forms of medication seemed to yield more readily, and active motion of the joints was attempted earlier. In the first fifteen cases the magnesium salt of phenylcinchoninic acid, thus reinforced, was used; in the second fifteen the ethyl ester of para-methyl-phenylcinchoninic acid was employed with magnesium. In both series this treatment was continued for nine days in daily doses, and was followed by a saline cathartic. Subsequently the patient received aceto-salicylic acid for about a week, when the magnesium combination was repeated, if necessary. No signs of any scleral icterus were detected. Emphasis is laid on the value of this treatment in inducing the patient to submit to joint movement at a much earlier date than in the case of other therapeutic procedures.

525 **Treatment of Meningococcal Meningitis**

T. GOLDMAN and A. G. BOWER (*Amer. Journ. Med. Sci.*, March, 1931, p. 414) record their observations on 50 cases of meningococcal meningitis in which specific serum was given by the cisternal route, as compared with 48 cases in which it was injected by lumbar puncture. Each of the 50 cases treated by cistern puncture received an average of 6.4 punctures, or two less than by the lumbar method. An average of 135 c.cm. of antimeningococcal serum was injected in the cisterna, and 128 c.cm. was given either intravenously or intraperitoneally, a total of 263 c.cm., or 30 c.cm. less than was used in treatment with the lumbar method. Of the 50 cistern cases 18 were fatal (36 per cent.), a difference in mortality of 22 per cent. in favour of the cisternal route; the difference was still greater after exclusion of 7 patients who died within twenty-four hours of admission.

526 **Treatment of Syphilis**

M. B. PAROUNAGIAN (*New York State Journ. Med.*, March 1st, 1931, p. 261) reviews the newer methods of treating syphilis, and concludes that arsphenamine is the drug of choice in early disease (chancre and secondaries) affecting young robust patients; he prefers neoarsphenamine for elderly persons, pregnant women, children, and patients with renal, cardiac, and other complications. Silver arsphenamine is useful in neurosyphilis,

extensive gummatous ulcerations, and anaemia, as well as for patients who cannot tolerate other arsenicals. Mercury is always to be included in the therapeutic attack on syphilis, but the reaction of the patient must be considered when deciding on the dosage, the duration of treatment, and the type of preparation likely to be most effective. Bismuth may be substituted for mercury when the latter is not well tolerated, and also when the patient has become sensitized to both arsphenamine and mercury. The author has at times observed some gratifying clinical improvement when colloidal bismuth is tried in cases of congenital syphilis and of tabes. Iodides are employed in all types of infiltrating lesions, such as persistent chancre, deep-seated secondaries, and gummatous deposits. Parounagian remarks that the latter-day acceptance of the possibility of syphilitic reinfection indicates that the newer methods are more successful than the earlier ones.

527 Calcium Gluconate in Oedema

W. S. O'Donnell and S. J. Levin (*Journ. Amer. Med. Assoc.*, March 14th, 1931, p. 837) commend the administration of calcium gluconate for the relief of oedema in children who are suffering from nephrosis. This salt, which contains 9.3 per cent. of calcium, is supplied in ampoules containing 15½ grains in about 10 c.cm. of water. No nausea or vomiting followed, and there were no undesirable sequels of any kind. Although the injections made into the oedematous tissues caused no harmful effects, it is suggested that it is better to give small doses of 10 c.cm. at different points, spaced apart, and subcutaneously. Ascites disappeared, and there was a decrease in the size of the abdomen. A general improvement in the appetite and health of the children was observable after the disappearance of the oedema; the dehydration of the bronchial mucous membranes seemed to have a good effect on the resistance to the dangerous respiratory complications, and the kidneys were also dehydrated concurrently without adverse signs developing. Details are given of three cases so treated; it was calculated that about 7½ grains were required for each pound of fluid removed. The dose necessary in each case could be estimated in advance, and the requisite amount of calcium gluconate be given rapidly in two doses so as to abolish the oedema without delay. It is necessary to keep such patients on a measured sufficiency of protein in the diet, in order to restore the lost blood protein and to keep the kidneys from secreting too much albumin.

528 Bromide and Iodide Therapy

According to V. E. Henderson and G. H. W. Lucas (*Canadian Med. Assoc. Journ.*, March, 1931, p. 412) there is no pharmacological reason for using any other bromide or iodide than the sodium salt. The preference attached by some physicians to the potassium, ammonium, and strontium salts seems to be based on the fact that very marked changes in the isolated heart and the intestines can be produced by increasing the percentage of potassium or calcium, but it is now recognized more and more that the active agencies are the bromide and iodide ions; the intensity of the effect of a bromide salt, for example, depends on the degree of substitution of bromide ion for the chloride, so that the patient who is not taking ordinary salt in his diet shows the effect of bromide therapy more rapidly. The only indication for the ammonium salt would be the need of giving a bromide base and at the same time changing the acid-base balance to the acid side. To make these salts palatable they should be well diluted, so that the solution, as taken, should not contain more than 15 grains to the ounce. The addition of syrup definitely improves the flavour. When the bromides are to be combined with hyoscyamus, both the flavour and the colour are very largely dependent on the quality used, a good tincture yielding a greenish solution, and a poorer one a brownish solution; clarity cannot be obtained without adding alcohol; otherwise, oily globules will separate after standing. Syrup of ginger is a useful addition, and so also is the extract of liquorice for those patients who do not dislike its flavour.

Disease in Childhood

529 The Diagnosis of Pulmonary Tuberculosis in Childhood

V. Poulsen (*Ugeskrift for Laeger*, February 5th, 1931, p. 125) discusses the not altogether rare cases in which a tuberculin reaction is positive in childhood but the stethoscopic and *x*-ray signs are inconclusive or negative, and it is impossible to diagnose pulmonary tuberculosis unless tubercle bacilli can be found in the sputum. As the sputum is usually swallowed in childhood, tubercle bacilli can be found only by washing out the stomach, and by a direct microscopical examination supplemented by cultures on Petroff's medium and inoculation of guinea-pigs. After recording several cases showing that open pulmonary tuberculosis may exist without stethoscopic or *x*-ray signs, the author insists that the demonstration of tubercle bacilli in the contents of the stomach must be accepted as conclusive evidence of pulmonary tuberculosis, provided the child is not suffering from tuberculosis of the tonsil or stomach or a tuberculous gland which has broken into the oesophagus, and has not consumed the unboiled milk of a tuberculous cow. He does not accept the suggestion that tubercle bacilli may be innocent incidental occupants of the stomach in the same way that diphtheria bacilli and pneumococci may exist in the mouths of healthy persons. In this connexion he quotes the observations of N. R. Christoffersen, who washed out the stomachs of 30 tuberculin-negative children and did not once succeed in demonstrating tubercle bacilli. As this diagnostic method is both unpleasant and expensive, it should not be resorted to when it is possible to diagnose pulmonary tuberculosis definitely by other means. Poulsen has examined altogether 110 children up to the age of 8 in this way, and has found tubercle bacilli in 53. Among the 62 children under the age of 3 years there were as many as 41 whose stomachs contained tubercle bacilli, whereas among the 48 children over this age there were only 12 harbouring tubercle bacilli in the stomach. Among the 53 positive cases there were only 38 in which tubercle bacilli were found at the first examination, and it should therefore be repeated twice, thrice, or oftener in suspect cases.

530 Types of Enuresis

L. Mandel (*Brit. Journ. Child. Dis.*, January–March, 1931, p. 1) distinguishes five types of enuretics with their appropriate treatment as follows. (1) Those children in whom some palpable physical irritating stimuli exist, such as worms, overdistension of bladder, or cystitis; in these cases the treatment is obvious. (2) The hypersensitive or neuropathic type which responds to dietetic and medicinal measures, combined with readjustment of the environment and gentle re-education. (3) The so-called psychopathic child, in whom the enuresis is more a behaviour complex, and the treatment required is for the most part psychological. (4) Endocrine dysharmony, particularly hypothyroidism leading to a loss of inhibition; in such cases small doses of thyroid with pituitrin as an adjuvant are indicated. (5) The debilitated child, often convalescent from some illness, for whom general tonic treatment is indicated. In all types atropine or belladonna is the specific drug of choice.

531 Meningococcal Meningitis in Infants

V. Cantalamessa (*La Pediatria*, March 1st, 1931, p. 233) records 42 cases of meningococcal meningitis occurring in children between the ages of 1 and 12 months. He remarks that the high mortality in such cases is partly due to the difficulty of diagnosis in the early stages; thus in 22 out of his 42 cases the disease began with irregular fever, restlessness, vomiting, and slight diarrhoea. Rapid pulse and respiration rates with no suspicious signs in the lungs, and associated with only moderate fever, may arouse suspicion, as also should hyperaesthesia. Lumbar puncture often reveals the nature of the malady. The fontanelle is generally tense, but where there is much diarrhoea this helpful sign may fail. Rigidity of the neck, frequently

associated with opisthotonos, was present in every case, and in no instance was there seen the flaccidity of the neck described by Netter. General convulsions were observed in 24 cases, but herpes was not present in any. Some degree of leucocytosis was noted. In four cases the course of the disease was apyretic; two of these patients died. In ten cases there was evidence of some obstruction of the cerebro-spinal fluid, in the form of a persistently tense fontanelle after lumbar puncture; the mortality was very high in this group (9 out of 10). The cases which began with a brusque onset (20) were more usually fatal than those beginning gradually. The duration of the disease ranged widely from three or four days to fourteen or fifteen weeks. Moderate enlargement of the spleen was noted in a few cases. In spite of specific serotherapy the mortality reached as high as 75 per cent.

Obstetrics and Gynaecology

532 Etiology of Eclampsia

R. H. PARAMORE (*Gynécol. et Obstét.*, February, 1931, p. 114) believes in the mechanical origin of eclampsia. He maintains that this condition is not brought about by biological or chemical causes, but by physical ones. As a result of his researches twenty years ago on the evolution of the pelvic floor in vertebrate non-mammifers and in pronograde mammals, it appeared that intra-abdominal pressure was directly interdependent on the general metabolism. As a corollary to this fact he suggests that eclampsia might be a result of changes in the intra-abdominal pressure. It is known that seven out of ten eclamptics are also primiparae. Nearly always the woman is young, active, and strong, working much about the house and eating well. Eclampsia supervenes either at the time when she works more and eats more, or later when she has to submit to violent movements and alterations of abdominal pressure. The kidneys, liver, and colon relieve the blood of waste products which can, if retained, give rise to grave intoxications of which eclamptic crises are examples. These organs depend for their efficiency on the amount of blood passing through them, and this in turn is regulated by the intra-abdominal pressure. The chief difference between the abdomen of the primipara and that of the multipara is the amount of pressure that can be exerted by the abdominal walls. The stronger the woman the more she works and eats, the greater the amount of work thrown on the viscera, and the greater the need for free circulation of the blood. Paramore deals fully with the question why the viscera do not hypertrophy to meet this demand. He instances twin pregnancies (in which eclampsia is four to five times as frequent as in single pregnancy), hydramnios, concealed intrauterine haemorrhage, and hydatidiform mole as parallel conditions in which pressure is increased and in which a toxaemia comparable to eclampsia may be produced. The objection that large intra-abdominal tumours do not cause eclampsia is met by the statement that the growth of a tumour is gradual, and therefore the muscles regulating the pressure have time to accommodate themselves, whereas the increase in size of a pregnant uterus is relatively very rapid, and there is not time for a similar adjustment to take place.

533 Pre-adolescent Ovarian Tumours

Ovarian tumours in children are rare, and a correct preoperative diagnosis is seldom made. R. K. FINLEY (*Surg., Gynecol. and Obstet.*, March, 1931, p. 723) reports the case of a patient, 9 years old, in which, since an immediate operation was not indicated, time permitted of an accurate diagnosis by utero-salpingography. An injection of 3 c.cm. of lipiodol was made into the uterus, and an *x*-ray picture was taken; another 2 c.cm. of the oil was then injected, and a second photograph was obtained. The plates showed torsion of a right ovarian cyst. Torsion of the uterine adnexa before puberty is extremely rare, and such cases seem to fall under three headings: torsion of abnormal adnexa, of normal adnexa in abnormal sites, and of apparently normal adnexa normally situated. These different types are described, and short reports are appended of 25 cases illustrative of each type which have been recorded since 1920.

534 Hydatidiform Mole, Chorion-Epithelioma, and the Zondek-Aschheim Reaction

According to M. REEB (*Bull. Soc. d'Obstét. et de Gynécol. de Paris*, January, 1931, p. 94) 50 per cent. of chorion-epitheliomata follow hydatidiform mole, 25 per cent. an abortion, and 25 per cent. pregnancy at term; one in twenty cases of hydatidiform mole is followed by chorion-epithelioma. That a mole is malignant cannot be decided microscopically, and so the probable supervention of chorion-epithelioma cannot be thus predicted. Careful supervision of the patient must continue after expulsion of a hydatidiform mole; until latterly, repeated clinical examinations and curettings were required for early detection of a chorion-epithelioma, but more recently the Zondek-Aschheim urine test, which is strongly positive in chorion-epithelioma, has furnished a more reliable mode of diagnosis. Biological diagnosis is also easier, for in the case of histological diagnosis from curettings it has to be remembered that many chorion-epitheliomata are atypical; sources of error are present, moreover, in the benign chorionic invasions of muscle which occur during and after normal pregnancy, and in the decidual myometrial reaction. Zondek and Aschheim showed that the urine of a patient harbouring living chorionic villi contains a substance which, injected into immature mice, produces in the ovaries follicular haemorrhages and lutein formations; this reaction becomes negative shortly after death of the ovum and four to six days after labour. In the presence of hydatidiform mole and chorion-epithelioma the hormone is found in the urine in ten to three hundred times the concentration of normal pregnancy. The reaction may remain positive for twenty to twenty-five days after evacuation of a hydatidiform mole; if it remains positive longer, even in the absence of metrorrhagia, curetting should be performed and chorion-epithelioma suspected. If after a hydatidiform mole the Zondek-Aschheim reaction becomes negative, and then again positive, either a new conception has occurred, or a uterine or ectopic chorion-epithelioma is present; quantitative findings may here be decisive. A. GINGLINGER (ibid., p. 99) describes a case in which the Zondek-Aschheim test led to the diagnosis of chorion-epithelioma (verified at operation), in the absence of clinical signs or symptoms, three months after expulsion of a hydatidiform mole.

535 Treatment of Eclampsia

H. SCHMORELL (*Zentralbl. f. Gynäk.*, March 14th, 1931, p. 654) records the case of a primipara, aged 30, who became comatose after a second fit of post-partum eclampsia, and whose condition became steadily worse in spite of lumbar puncture, venesection, and Stroganoff therapy. She received 650 c.cm. of 12 per cent. dextrose solution, containing 20 units of insulin and 0.48 gram of euphyllin, by slow intravenous injection lasting two hours. Diuresis speedily became established, and cure followed; later on 20 per cent. dextrose solution had been administered by the rectum. Injections of hypertonic dextrose solution in eclampsia have previously been recommended by Bokelmann and Dieckmann (*Arch. f. Gynäk.*, 1930). The objective of this treatment is (1) to reduce tissue oedema, especially in the brain; (2) to promote diuresis; and (3) to stimulate the detoxicating activities of the liver, in which the glycogen content is seriously depleted.

536 Treatment of the Vomiting of Pregnancy

H. GUGGENHEIMER (*Deut. med. Woch.*, January 23rd, 1931, p. 149) strongly advocates the use of bromides in cases of persistently severe vomiting of pregnancy. He gives, as a clyster, two tablespoonfuls of 10 per cent. solution of sodium bromide at night, and one tablespoonful in the morning. If after a few days the vomiting ceases, the dose of bromide is halved, and the morning dose is omitted or may be given by the mouth. To avoid relapse it is advisable to give 1 to 2 grams of bromide at night for several weeks. The patient is kept in bed during the first week.

Pathology

537 Heart Failure and Metabolism

H. SCHWARZ, H. DIBOLD, and D. RAPPAPORT (*Wien. klin. Woch.*, February 27th, 1931, p. 280) estimated the reducing power of the urine—that is, its content of unoxidized substances—daily for at least six to eight days in a number of normal subjects, and for a longer period in a number of cardiac patients, all kept on a standard diet; they have expressed the result of this investigation in terms of "urinary oxygen deficiency" (Vakatsauerstoff). The figure varied somewhat in normal subjects, but never in these exceeded 10 grams a day; in pathological conditions it might be as high as 30 or 40 grams. The variations were apparently independent of the type of diet, whether pure carbohydrate, mixed, or with low fat content. The cardiac cases examined fell into two groups. Those with a tendency to oedema showed normal or low normal urinary oxygen deficiency values, which increased considerably as the condition improved. The second group comprised cases of heart failure without marked oedema; the urine contained large amounts of unoxidized substances, which diminished again as the general condition of the patients improved under treatment. Further tests showed that the reducing substances responsible were mainly non-nitrogenous, and were to some extent proportional to the amount of lactic acid in the urine. The fact that a fruit and carbohydrate diet increases the lactic acid in the urine, without increasing that in the blood, and is known to have a beneficial effect on the oedema, is regarded as evidence that the increased reducing value of the urine shown in these tests is due to defective intermediate oxidation in the tissues. That it is not directly due to stasis in the liver is shown by the fact that a levulose test on the same cardiac patients did not produce any definite pathological rise in blood sugar. It is suggested that further chemical study along these lines may throw light on the general metabolic changes associated with heart failure.

538 Absorption of Tetra-ethyl Lead

R. A. KEHOE and F. THAMANN (*American Journ. of Hygiene*, March, 1931, p. 478) record experiments on rabbits which show that tetra-ethyl lead is absorbed through the skin. Its initial distribution through the tissues corresponds with that of an oil-soluble material, and it appears, therefore, that some portion of this lead derivative is absorbed and circulates in this form. It is, however, rapidly decomposed by the tissues, including the skin, and so only a small portion of the lead found later in the blood is in the tetra-ethyl form. After a period of from three to fourteen days all the lead in the tissues is distributed in the characteristic form of water-soluble lead compounds. In small doses the factors of rapid decomposition and low concentration in the blood interfere with the distribution of this lead preparation to such an extent as to prevent its primary absorption by the nervous system. Tetra-ethyl-lead poisoning resembles the poisoning produced by other lead compounds, but evidence was obtained by the authors that its absorption from petrol in concentrations not exceeding 0.1 per cent. was not followed by any appreciable results.

539 The Preparation of Tetanus Anatoxin

S. HOSOYA, M. TAKADA, and S. TERAO (*Japan. Journ. Exper. Med.*, February, 1931, p. 33) describe the preparation of anatoxin from a purified tetanus toxin. Anatoxin, as usually prepared by the formolization of broth cultures, contains a number of non-specific substances which are more or less objectionable; moreover, its preparation takes four weeks or longer. The method described by the authors involves the production of a high-grade toxin by growth of the tetanus bacillus in a liver and meat infusion broth for ten days, with subsequent filtration; such a filtrate should prove fatal to mice in a dose of 0.0001–0.00005 c.cm. To it is added 2 per cent. aqueous zinc chloride solution. The toxin comes down in the precipitate, which is washed repeatedly with distilled water and ground up in a mortar. The precipitate is then dissolved in ammonium citrate solution, and the zinc is thrown out by the addition of ammonium sulphide. The zinc sulphide precipitate is removed, and the remaining filtrate is dialysed against running water for twenty-four hours. The non-dialysable fraction, which is neutral, clear, and faintly yellow, contains the purified tetanus toxin, with a lethal dose similar to that of the original crude toxin. To the purified toxin 0.4 per cent. of formol is added, and the mixture is incubated at 37° C. After forty-eight hours it is completely innocuous for mice, even in a dose of 0.5 c.cm. Immunization tests on guinea-pigs and horses indicated that this formolized toxin had considerable antigenic powers; animals injected with it were protected against the injection of toxin or of living tetanus bacilli.

540 Immunization against Typhus Fever

H. ZINSSER and M. R. CASTANEDA (*Journ. Exper. Med.*, March, 1931, p. 325) record experiments in which they succeeded in conferring an appreciable degree of immunity to typhus fever on guinea-pigs by vaccination with a formolized virus. The vaccine was prepared by grinding up infected tunica vaginalis tissue, and exposing it overnight to a saline solution containing 0.2 per cent. formol. Three injections were made in about a fortnight, the dose each time corresponding to one-third of a single tunica. The test inoculations, consisting of a mixture of defibrinated blood and brain of an animal inoculated with European typhus virus, were given seventeen to twenty-one days after the last vaccination. In the first experiment three control animals showed a typical febrile course following inoculation, while in the six vaccinated animals the disease ran a milder course, one animal proving completely resistant. In the second experiment the two control animals showed the usual fever, while three out of five vaccinated animals showed no reaction; of the remaining two vaccinated animals, one showed a typical and the other a modified febrile reaction. In a second paper H. ZINSSER, M. R. CASTANEDA, and C. V. SEASTONE (ibid., p. 333) describe the greatly increased susceptibility to experimental typhus of guinea-pigs and rats fed on a vitamin deficient diet. In such animals the disease is much more severe; the temperature may rise on the day after inoculation, or there may be very little febrile reaction; some of the animals die, and nearly all of them show enormous numbers of rickettsiae in the peritoneum and the tunica vaginalis. Besides being of interest from the epidemiological point of view in suggesting why typhus fever is so closely related to war and famine, these experiments indicate how exudates may be prepared which are very rich in rickettsiae, and which are therefore eminently suitable for the preparation of vaccine.

541 Estimation of Glycaemia

L. PINELLI and A. CORBIA (*Biochim. e Terap. Speriment.*, January 31st, 1931, p. 19) have examined different methods for estimating the sugar content of the blood in healthy and in sick persons, especially those of Folin-Wu, Schaeffer-Hartmann, Hagedorn-Jensen, Jonescu-Mathiu, and Bertrand-Silvestri. They conclude that the methods based on the reduction of salts of iron, especially the Jonescu-Mathiu method, give more constant and less variable results than those involving the reduction of salts of copper. The authors maintain that the minimum and maximum values of blood sugar content should never be regarded as absolute, but only as values relative to the special method employed in the estimation.

542 Actino-sensitivity of Oestrin

F. LUDWIG and J. V. RIES (*Zentralbl. f. Gynäk.*, January 17th, 1931, p. 137) have confirmed the observation of Allen and Ellis that the activity of the oestrus-producing follicular hormone is destroyed by exposure to ultra-violet radiation. They find, in addition, that exposure to the red rays leads to a twofold increase in the activity of oestrin as tested in the mouse, and that red radiation restores the activity of oestrin which has been subjected to ultra-violet radiation. *X*-radiation is without effect on oestrin.

Clinical Report from a British Hospital on

LEO GASTROSIC

To C. L. BENCARD, LTD., 8th May, 1931.
184, WARDOUR STREET, LONDON, W.1.

DEAR SIRS,

I think you may be interested to hear of the sample of "Gastrosic Leo" which you kindly sent me on 7th April.

On that day a woman was admitted to this Hospital with primary (pernicious) anaemia. She was desperately ill and was given two tubes of liver extract daily until April 18th, when 10 grammes of "Gastrosic Leo" was substituted for it and given daily in stout.

The patient made a remarkable recovery as the result of the blood examination shows.

On the third day she was given a blood-transfusion of 300 c.cm.

Date.	Red cells.	Haemoglobin.	Colour-index.	White cells.
8/4/31	788,000	16%	1.14	7,600
22/4/31	1,376,000	27%	8.0	11,600
2/5/31	4,268,000	55%	0.65	

Yours truly,
(signed) Physician, M.D.

The remarkable feature of the above report is that the increase in red blood and haemoglobin took place during 11 days with only 10 grammes of "Gastrosic Leo" administered daily, and as the price of "Gastrosic Leo" is only 10s. for 18 packets of 10 grammes each, the improvement in the patient's condition from the 22nd April to the 2nd May only cost 6s. 2d.

Samples and full particulars can be obtained from the above or from
JAMES WOOLLEY, SONS & CO., LTD., Victoria Bridge, Manchester.
South African Distributors: LENNON LTD., Cape Town and Branches.

THEY STIMULATE!

THEY REVIVE!

THEY SUSTAIN!

BECAUSE they supply energy almost at once without effort or strain to the digestive organs, Brand's Essences of Beef or Chicken are recommended by the entire medical profession of Great Britain.

99 out of every 100 doctors interviewed recently prescribe them in severe illnesses and during convalescence when the patient's recovery is so often hampered by anorexia.

Suave and non-irritant, they are particularly suitable in all cases of intestinal disturbances, in specific fevers and before and after operations. Assimilated by the digestive organs forty minutes quicker than ordinary foods and without the formation of residue, Brand's Essences revive vitality and quickly prepare the system to accept a solid diet.

Brand's Essences are hygienically prepared by an exclusive process from the finest freshly killed English meats. No preservatives or colouring matter, just the pure essences, condensed in their clear natural form—easy to swallow and delicious to taste.

Samples will be gladly sent on receipt of a professional card. Dept. F34, Brand & Co. Ltd., Mayfair Works, South Lambeth Road, London, S.W.8.

When a life is at stake....

The psychological moment has arrived. Will the operation be successful? . . . Can modern science triumph over such disease? . . . The surgeon bends closer over the table . . . deft fingers touching slender instruments . . . a life is at stake . . . if the lights should fail, plunging the theatre into darkness . . .

Nowhere is reliable light supply more important than in operating theatres. A light failure may have far-reaching consequences. Every hospital should be equipped with Ediswan Stationary Battery. Then if current fails, a switch over to the Ediswan saves the situation and restores light almost immediately.

The Ediswan Stationary Battery for Emergency Lighting is compact and robust. It takes up little space and is sturdily built to give long service. Running costs are almost negligible. Installation costs are low.

May we co-operate with you in evolving a Battery specially to suit your requirements?

TO COUNTER ACIDOSIS

As SALVITAE contains 59% of Potassii et Sodii Citro-Tartras and 30% of Sodii Sulphas it is of great value both in maintaining health and in the treatment of disease, through eliminating deleterious nitrogenous products and favourably influencing circulation, glandular secretions, peristalsis, and metabolism.

The fruit acids of SALVITAE are converted in the system into potentially basic alkaline carbonates, thus enabling the blood to keep the uric acid compounds in solution, and facilitate their removal.

"VARIBAN"

Elastic Plaster BANDAGE

MADE from a specially woven selvedge material, possessing very elastic properties, evenly spread with an Antiseptic Zinc Oxide Paste. Self-adhesive, readily conforming to the shape of the limb, and when carefully applied forms an even surface dressing which will not crease or slip. Firm support. Easy to remove. Extensively used in many well-known hospitals for the treatment of VARICOSE ULCERS, VARICOSE VEINS, SURGICAL and ORTHOPAEDIC CASES, etc. Their application for treatment of Varicose Ulcers, etc., does not necessitate the patient lying-up; in fact, permits the continuance of light duties. Ensures rapid healing.

ST. ANDREW'S HOSPITAL

FOR MENTAL DISORDERS,

NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or who wish to prevent recurrent attacks of mental trouble; temporary patients; and certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. *Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.*

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

TYKEFORD ABBEY, NEWPORT PAGNELL,

BUCKS.

FUNCTIONAL NERVOUS DISORDERS, MEDICAL & CONVALESCENT CASES.

SWISS SPAS

BADEN.

On the main line Zürich-Basle and Zürich-Berne. The hot springs of Baden were already known to the Romans. 17 radio-active wells at a temperature of 118.4°F. They contain sulphur and sodium chloride. The baths are obtainable in the hotels themselves. Treatments: warm baths, shower baths, massage, electric baths, inhalation, drinking cure, diagnostic-therapeutic institute, mechanotherapy. Recommended for metabolic diseases, rheumatism, gout, sciatica, diseases of the muscles, bones, and joints, retarded convalescence after injuries and operations.
Season: April 1st to November 1st.
For information apply to: Spa Director, Baden, Switzerland.

LOÈCHE-LES-BAINS.

One hour by electric railway from Loèche (main station on the Simplon route). Mild alpine climate. The baths were already known to the Gauls and Romans. The radio-active springs contain chiefly sulphate of lime. Two swimming pools. Every hotel has its own bathing installation. Treatments: warm baths, douche-massage, injections, air and sun baths. Recommended for: gout, rheumatism, sciatica, anaemia, post-operational conditions, convalescence, gynaecological diseases, circulatory disturbances, skin diseases.
Season: May to October.
For information apply to: Hotel Association, Loèche-les-Bains, Switzerland.

PASSUGG.

Near Chur. Situated on a picturesque plateau. Mild sub-alpine climate. Vast forests.
Treatments: The Ulricus spring (alcaline-muriatic), Belvedra spring (chalybeate), Fortunatus spring (alcaline-muriatic with iodine), Helen spring (mildly alcaline and acid), Theopnil spring. All varieties of accessory treatment. Dietetic treatment. Indications: Diseases of the digestive organs, diseases of the liver and bile ducts, kidney and bladder diseases, diseases of nutrition and metabolic diseases, especially diabetes, arterio-sclerosis, diseases of the blood and tropical diseases.
Season: May to October.
For information apply to: Spa Director, Passugg, Switzerland.

RHEINFELDEN.

10 miles from Basle, on the railway line Zürich-Basle. Famous for its vigorous brine, containing 31% salt, and for its "Kapuziner" spring, a highly diuretic calcium and boric acid well, and for its "Magdalena" spring, containing sulphates of calcium, sodium, and magnesium. 8 bath establishments with up-to-date installations. Treatments: brine baths, carbonic acid brine baths, drinking, mud-packs, "Mutterlauge" packs, inhalation, massage, gymnastics, all varieties of electric treatment, dietetic treatment. Recommended for: gout, rheumatism, arthritis, women's diseases, sterility, obesity, children's diseases, arterial hypertension, diseases of the heart, affections of muscles, bones, and joints, convalescence.
Any information and detailed booklet gladly supplied by: Enquiry Office, Rheinfelden, Switzerland.

SCHINZNACH.

Railway connections: Basle-Brugg-Zürich, and Berne-Brugg Zürich. The hot springs of Schinznach were in use in Roman times and belong to the strongest radio-active sulphur wells on the Continent. Newly equipped, comfortable baths and inhalation rooms. Treatments: baths, drinking, sulphur-mud and sulphur-water packs, irrigations, inhalatorium, massage, X-rays. Recommended for: gout, rheumatism, affections of bones and joints, non-tuberculous catarrhs of the air passages, arterio-sclerosis, diseases of the skin, diseases of women, children's diseases.
Season: May to October.
For information apply to: Spa Director, Schinznach Bad, Switzerland.

TARASP-SCHULS-VULPERA.

The chief spa of the Lower Engadine. Glauber salts wells. The advantage of this spa lies in the combination of the curative properties of the waters with the alpine air and sun.
10 mineral springs of various composition. Up-to-date equipment for drinking and baths, air and sun baths, swimming baths, Zander-hall, X-ray institute, diet. Recommended for: affections of the digestive organs, metabolic ailments, nervous troubles, affections of the organs of circulation, of the organs of respiration, of the genito-urinary system, malaria.
Information supplied by: General Manager, Kurhaus Tarasp.

The introduction of special dietary tables for diseases of the digestive organs and the kidneys, as well as for diabetes, permits the physician to treat to the fullest extent each patient individually.

For information and the booklet "Swiss Spas and their Mineral Springs" (sent gratis), please apply to the Office of the Swiss Federal Railways, 11b, Regent Street, London, S.W.1.

Excellent Trout Fishing

BRITISH SPAS
ARE BEST

and membership of the British Spas Federation is a guarantee of efficiency

AT British Spas, treatment is only given (except in a few minor cases) upon medical prescription.

At British Spas the staffs are educated and properly trained and, in some cases, medically trained and medically certificated.

Equipment and administration are thoroughly up to date and scientific. Every new treatment is tested and reported upon before being adopted.

British Spas are also remarkably fortunate as regards situation, scenic beauty and pure air. These factors, combined with the social amenities of a home town, aid the cure considerably.

BATH Hot Springs (120° F.) Radio-active. Royal Baths extensions now open.

BRIDGE OF ALLAN Saline Water. Rich Calcium Bromide and Iodine Content.

BUXTON Radio-active Mineral Water. New Natural Baths. 3 Guineas Course.

CHELTENHAM Five Natural Waters. Modern Baths.

DROITWICH The Brine Baths Spa in charming Worcestershire.

HARROGATE 88 Waters. 100 Treatments. Medically certificated staff.

LEAMINGTON Advanced Spa Treatment. Saline Springs.

LLANDRINDOD WELLS The Modern Welsh Spa.

TREFRIW WELLS Rich Sulphate Chalybeate Waters.

WOODHALL SPA Bromo-Iodine Waters. Pinewoods. Restful Air.

A New Medical Handbook is being published, specially prepared for the use of the medical profession. A copy will gladly be sent you if you will write to the Hon. Secretary, Box 1, British Spas Federation, Pump Room, Leamington Spa, or to the Managers of any of the Spas here mentioned.

City of Manchester.

PUBLIC HEALTH DEPARTMENT.

WITHINGTON HOSPITAL.

APPOINTMENT OF TWO ASSISTANT MEDICAL OFFICERS.

The Public Health Committee invites applications from qualified Medical Men for the positions of Two Assistant Medical Officers at the Withington Hospital (1,200 beds), and Institution (1,150 beds), Nell Lane, West Didsbury, Manchester.

Every applicant must be a registered Medical Practitioner and unmarried.

Preference will be given to applicants with previous Hospital experience.

The Hospital is a recognised Training School for Nurses, and is equipped with all modern requirements.

Salary £275 per annum in each case, with board, residence, and laundry in addition. No bonus.

The appointments will be made, in the first instance, for a period of six months. The successful candidates, however, will be eligible for re-appointment for a further period of six months at the end of that period.

Every application, stating fully the training, qualifications, and experience of the candidate, and his age, with copies of three recent testimonials, and endorsed on the envelope "Assistant Medical Officer, Withington Hospital," must be addressed to the Medical Officer of Health, Civic Buildings, 1, Mount Street, Manchester, only, and not to members of the Committee or Council, and must be received by him not later than Thursday, June 4th.

One candidate appointed will be required to commence duty on August 4th, and one on September 1st. Each candidate appointed will be required to devote the whole of his time to the duties of the position, to pass a medical examination, to contribute to the Corporation Superannuation Fund, and to execute the Deed of Service.

Canvassing in any form, oral or written, direct or indirect, is prohibited.

F. E. WARBRECK HOWELL,
Town Hall, Town Clerk.
Manchester. May 18th, 1931.

County Borough of West Bromwich.

HALLAM HOSPITAL.

RESIDENT HOUSE SURGEON.

Applications are invited from fully qualified male registered Practitioners (single) for the above appointment.

The appointment is for twelve months, but either party may give six weeks' notice terminating the engagement. The Hospital has 474 beds, and is equipped with up-to-date Special Departments. There is a visiting staff of eight Consultant Physicians and Surgeons.

Preference will be given to applicants with previous Hospital experience.

Salary £250 per annum.

Canvassing, either directly or indirectly, is strictly prohibited and will be deemed a disqualification.

Applications, stating age, experience, and qualifications, together with copies of three recent testimonials, must be forwarded to the Medical Officer of Health, 2, Lodge Road, West Bromwich, so as to arrive not later than by first post on Wednesday, June 10th.

Town Hall, ALFRED WICKHAM,
West Bromwich. Town Clerk.
May 16th, 1931.

The Walsall and West Bromwich (BARR & WIGMORE) JOINT COMMITTEE.

Great Barr Children's Homes and Great Barr Park Colony for Mental Defectives.

APPOINTMENT OF ASSISTANT RESIDENT MEDICAL OFFICER.

The Committee invite applications for the appointment of Assistant Resident Medical Officer for the Institutions at Great Barr Park.

The appointment will be for a period of twelve months and the salary at the rate of £275 per annum, together with the usual residential emoluments.

The officer appointed must devote the whole of his or her time to the duties and will be required to act under the general direction of the Medical Officer.

Canvassing, either directly or indirectly, is strictly prohibited and will be deemed a disqualification.

Applications, stating age, experience, and qualifications, accompanied by copies of not more than three recent testimonials, must reach me not later than Monday, June 8th.

By Order,
22, Lombard St., A. H. WARD,
West Bromwich. Clerk.
May 21st, 1931.

City of Carlisle.

APPOINTMENT OF ASSISTANT MEDICAL OFFICER OF HEALTH.

The Council of the City and County Borough of *Carlisle* invite applications for the appointment of Assistant Medical Officer of Health, at a salary of £650 per annum, rising by annual increments of £50 to a maximum of £750 per annum. The duties of the appointment are principally those connected with the diagnosis and treatment of Tuberculosis and the medical inspection and treatment of school children, including Eye Work and Refractions.

Candidates must not be more than 40 years of age, and must be fully qualified and registered Medical Practitioners, holding the Diploma in Public Health or an equivalent qualification.

Candidates must either have held a previous appointment as Tuberculosis Officer with the approval of the Minister of Health, or, subsequent to qualification:

(1) Have had at least three years' experience in the practice of their profession;
(2) Have spent in general clinical work a period of not less than eighteen months, of which not less than six months have been spent in a Hospital as Resident Officer in charge of beds occupied by general medical or surgical cases; and
(3) Have received special training for a period of not less than six months in the diagnosis and treatment of Tuberculosis.

The gentleman appointed will be required to devote the whole of his time to the duties of the office, to reside in the City, and will not be allowed to engage in private practice.

The appointment is an established post under the Local Government and Other Officers Superannuation Act, 1922, and the gentleman appointed will be required to pass a medical examination, and contribute 5 per cent. of his salary to the Superannuation Fund.

The Committee also employ a Female Assistant, who is the Medical Officer for Maternity and Child Welfare, and undertakes part of the work of School Medical Inspection.

Applications, stating age, qualifications, and experience, accompanied by copies of not more than three recent testimonials, and endorsed "Assistant Medical Officer of Health," must reach me not later than the first post on Thursday, June 4th.

Canvassing, either directly or indirectly, is prohibited.

Applicants may, if they desire, forward stencilled copies of their applications and testimonials to the members of the Selection Committee, a list of whose names will be supplied by the undersigned upon request.

FREDK. G. WEBSTER, Town Clerk.
Town Clerk's Office, Carlisle.
May 19th, 1931.

City of Cardiff.

LLANDOUGH HOSPITAL.

MEDICAL SUPERINTENDENT.

Applications are invited from duly qualified Medical Practitioners (who have had experience of Hospital administration) for the appointment of Medical Superintendent of Llandough Hospital.

The Hospital, which is now in course of construction, is a *Municipal General Hospital*, where 340 beds will be provided in the first instance, under the management of the Health Committee.

Until the opening of the Hospital the Medical Superintendent will be engaged in its preparation and equipment, and will also act as Part-time Medical Officer of the City Lodge Poor Law Institution, where there are three Resident Assistant Medical Officers.

The salary will be £750 per annum, rising by biennial increments of £50 to £950 per annum, with *emoluments (including house, with* heating, lighting, and laundry) valued at £150 per annum.

The person appointed, who must devote his whole time to the duties of the post under the direction of the Medical Officer of Health, will be required to contribute 5 per cent. of his salary to the Superannuation Scheme of the Council, and for this purpose to pass a medical examination.

Applications, on forms obtainable from the Medical Officer of Health, City Hall, Cardiff, accompanied by copies of three recent testimonials, and endorsed "Medical Superintendent," must be sent to the Medical Officer of Health so as to reach him not later than Monday, June 8th.

City Hall, CECIL G. BROWN,
Cardiff. Town Clerk.
May 18th, 1931.

Royal Lancaster Infirmary.

(106 Beds.)

JUNIOR HOUSE SURGEON (male, British) required immediately. Salary £130 per annum, with board, residence, and laundry.

Applications, with copies of testimonials, should be addressed to the Hon. Secretary.

Lancaster. May 13th, 1931.

County Borough of Bury.

ASSISTANT MEDICAL OFFICER OF HEALTH, ASSISTANT SCHOOL MEDICAL OFFICER, and ASSISTANT TUBERCULOSIS OFFICER.

The Corporation of Bury are prepared to receive applications for the post of Assistant Medical Officer of Health, Assistant School Medical Officer, and Assistant Tuberculosis Officer, at a salary of £500 per annum, rising by annual increments of £25 to £700 per annum.

The principal duties will consist of the Medical Inspection of School Children, Maternity and Child Welfare work, and the Diagnosis, Treatment, etc., of Tuberculosis, but the person appointed will also be required to assist the Medical Officer of Health in his other duties as the Health Committee may direct.

Applicants must be registered Medical Practitioners, must possess the Diploma of Public Health, and must have had at least three years' experience of Post-graduate Medical work. They must have had special practical experience in the Diagnosis and Treatment of Tuberculosis. Preference will be given to applicants who have taken a course in Mental Deficiency work.

The person appointed will be required to reside in the Borough.

Forms of application and terms of appointment can be obtained from the Medical Officer of Health, Clough Street, Bury.

Applications, endorsed "Assistant Medical Officer of Health," and accompanied by copies of three recent testimonials, must be forwarded to the undersigned not later than Monday, June 8th.

Municipal Offices, RICHARD MOORE.
Bank Street, Town Clerk.
Bury. May 20th, 1931.

Administrative County of LONDON.

HOSPITAL SERVICE.

The LONDON COUNTY COUNCIL invites applications for appointment as RESIDENT MEDICAL SUPERINTENDENT in the Public Health Department for duty at HAMMERSMITH HOSPITAL, Ducane Road, Shepherd's Bush, W.12. The duties also include those of Medical Officer and Acting Master of Hammersmith Institution.

The person appointed will be required to act under the direction of the Medical Officer of Health and, should occasion arise, to assist at any of the other establishments or medical districts under the control of the London County Council.

The salary is £950 a year, rising by annual increments of £50 to £1,200 a year. £100 a year extra will be paid so long as the officer is acting as administrative and medical head of the Institution. An unfurnished house or quarters, free of rates, taxes, or water charges, will be provided, valued provisionally at £100 a year.

Candidates must be duly qualified Medical Practitioners of at least five years' standing, and produce evidence of having held the appointment of House Physician or House Surgeon in a public General Hospital, and of having had experience of Hospital administration.

Forms of application may be obtained (stamped addressed foolscap envelope necessary) from the Clerk of the Council, The County Hall, Westminster Bridge, S.E.1, and must be returned by June 8th. Canvassing disqualifies.

MONTAGU H. COX,
Clerk of the London County Council.
The County Hall,
Westminster Bridge, S.E.1. May, 1931.

Administrative County of ESSEX.

MALE ASSISTANT COUNTY MEDICAL OFFICER OF HEALTH.

The County Council of the Administrative County of Essex invite applications for the above post from registered Medical Practitioners holding a Diploma of Public Health, and not over 45 years of age.

The commencing salary attached to the appointment will be from £500 to £600 per annum, according to experience, and will rise by annual increments of £25 to £700 per annum. Travelling expenses will be paid by the Council.

The Local Government and Other Officers Superannuation Act, 1922, has been adopted by the County Council.

Applications on the prescribed form, obtainable from the undersigned, and accompanied by copies of not more than three testimonials, which will not be returned, should be addressed to me and delivered at the Shire Hall, Chelmsford, *not later than 10 a.m. on Friday*, June 12th.

Shire Hall, JOHN H. GOOLD,
Chelmsford. Clerk of the County Council.
May 23rd, 1931.

The Hospital for Sick Children,
Great Ormond Street, London, W.C.1.

A HOUSE SURGEON and a HOUSE PHYSICIAN are required on July 1st.

Gentlemen are invited to send in their applications, addressed to the Secretary, before 12 o'clock on Monday, June 1st, with copies of not more than three testimonials given specially for the purpose, and also evidence of their having held a responsible Hospital appointment.

The appointments are made for six months. Salaries at the rate of £100 per annum, laundry allowance £5, board and residence in the Hospital.

Candidates must be unmarried, and possess a legal qualification to practise.

All candidates must be in attendance to appear before the Joint Committee, if required, at their meeting on Wednesday, June 3rd, at 5 p.m. precisely.

Forms of application and copies of the Rules may be obtained from the Secretary.

By Order of the Board of Management,
JAMES MACKAY, Secretary.

May, 1931.

RESIDENT HOUSE SURGEON required for six months. Honorarium at the rate of £100 per annum, with board, washing, etc. Apply to Senior Resident House Surgeon.

County Council of Durham.

DISTRICT TUBERCULOSIS MEDICAL OFFICER.

The County Health Committee invite applications for a District Tuberculosis Medical Officer, at a commencing salary of £500 per annum, rising by annual increments of £25 to £700 per annum. Travelling expenses will be paid by the County Council.

The appointment will be held subject to three months' notice on either side, and to the following conditions:

(1) The officer appointed must be a registered Medical Practitioner between the ages of 25 and 45 years, must devote the whole of his time to the duties of the office, and must not engage in private practice.

(2) He should either have held a previous appointment as Tuberculosis Medical Officer, with the approval of the Minister of Health, or

(i) Have had at least three years' experience in the practice of his profession;

(ii) Have spent in general clinical work a period of not less than eighteen months, of which not less than six months have been spent in a Hospital as Resident Officer in charge of beds occupied by general medical or surgical cases; and

(iii) Have received special training for a period of not less than six months in the diagnosis and treatment of Tuberculosis.

(3) He will be attached to the County Health Department, and will, subject to the directions of the County Medical Officer, be under the control of the Central Tuberculosis Medical Officer.

(4) He will be required to reside in his Dispensary area, or such other centre as required by the Council.

(5) He will be required to carry out the duties of a District Tuberculosis Medical Officer.

(6) He must be prepared, if called upon, to act as Locum Tenens to other members of the Medical Staff of the County Medical Officer.

(7) The holding of a Diploma in Public Health, and practical experience in Bacteriological Laboratory work, will be deemed additional qualifications for the post.

The candidate appointed will be required to pass the County Council's medical examination, and will be subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922.

Applications, endorsed "District Tuberculosis Medical Officer," and accompanied by copies of not more than three recent testimonials, must be addressed to the undersigned, and must be received by him not later than June 13th.

Shire Hall, Durham. C. FRANKS, County Medical Officer.

May 23rd, 1931.

County Borough of Walsall.

APPOINTMENT OF ASSISTANT CLINICAL TUBERCULOSIS OFFICER, ASSISTANT MEDICAL OFFICER OF HEALTH, AND ASSISTANT SCHOOL MEDICAL OFFICER (Male).

Applications are invited from Medical Men, not over the age of 35, for the appointment of an Assistant Clinical Tuberculosis Officer and Assistant Medical Officer of Health, etc.

Salary £750 per annum.

Applicants must be duly registered Medical Practitioners, holding a Diploma of Public Health, and should have had at least six months' experience since graduation as House Physician or House Surgeon in a General Hospital, together with special experience of Tuberculosis in Dispensary and Sanatorium Practice.

A knowledge of Bacteriology is essential.

Applications, on forms to be obtained from the undersigned, stating age, qualifications, training, and experience, together with copies of three recent testimonials, and endorsed on the envelope "Assistant Clinical Tuberculosis Officer," should be sent to the Town Clerk not later than Saturday, June 6th.

The person appointed will be required to devote the whole of his time to the duties, to reside in Walsall and to act under the administrative control of the Medical Officer of Health.

The appointment will be subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922.

Canvassing, directly or indirectly, will be considered a disqualification.

Council House, Walsall. HERBERT LEE, Town Clerk.

May 21st, 1931.

Manchester Ear Hospital,

GROSVENOR SQUARE, ALL SAINTS'.

The Board invite applications for the post of NON-RESIDENT HOUSE SURGEON. 24 beds. Salary at the rate of £150 per annum, with partial board. Candidates must be duly qualified and registered. Applications, with copies of four recent testimonials, to be forwarded to Mr. REGINALD S. MILFORD (Hon. Secretary, Manchester Ear Hospital), c/o Mr. W. J. ELLAM, 33, Brazennose Street, Manchester.

Durham County Council and CHESTER-LE-STREET URBAN DISTRICT COUNCIL.

APPOINTMENT OF DISTRICT TUBERCULOSIS MEDICAL OFFICER AND MEDICAL OFFICER OF HEALTH (Male).

Applications are invited for the above appointments. Candidates must be registered in the Medical Register as holding a Diploma in Sanitary Science, Public Health, or State Medicine, and must have had a satisfactory experience in the diagnosis and treatment of Tuberculosis.

The salary will be £800 per annum, in the proportion of £572 15s. payable by the County Council, and £227 5s. payable by the Chester-le-Street Urban District Council.

The officer appointed must either have held a previous appointment as Tuberculosis Medical Officer, with the approval of the Minister of Health, or

(i) Have had at least three years' experience in the practice of his profession;

(ii) Have spent in general clinical work a period of not less than eighteen months, of which not less than six months have been spent in a Hospital as Resident Officer in charge of beds occupied by general medical and surgical cases; and

(iii) Have received special training for a period of not less than six months in the diagnosis and treatment of Tuberculosis.

Travelling and subsistence allowances according to scale will be paid by the County Council in respect of the duties of District Tuberculosis Medical Officer, and the officer will, subject to the directions of the County Medical Officer, be under the control of the Central Tuberculosis Medical Officer.

It will be a condition of the appointment that if either post is terminated, the other post will be automatically vacated.

The appointments will be subject to the approval of the Minister of Health; and the officer will not be permitted to take part in private practice.

The person appointed will be required to live in or near Chester-le-Street.

Applications, endorsed "T.M.O. and M.O.H.," and accompanied by copies of not more than three recent testimonials, must be addressed to the undersigned, and must be received by him not later than June 13th.

Shire Hall, Durham. C. FRANKS, County Medical Officer.

May 23rd, 1931.

Birmingham Public Health DEPARTMENT.

TUBERCULOSIS SECTION.

Applications are invited from single male Medical Practitioners for the post of ASSISTANT MEDICAL OFFICER in the Tuberculosis Section of the Public Health Department. The successful candidate will be employed both in a Sanatorium and in a Dispensary.

Candidates should have held a resident General Hospital appointment or an appointment in some Institution set apart for the treatment of those suffering from Tuberculosis.

The salary will be at the rate of £400 per annum, rising by annual increments of £25 to £450 per annum, with emoluments valued at £150 per annum.

The officer appointed will be required to refund to the Council all fees, allowances, and emoluments (other than the foregoing) received by him.

The appointment will be subject to the Birmingham Corporation's Superannuation Scheme, and to the candidate passing a medical examination, and will be subject to one month's notice on either side.

Forms of application may be obtained from, and should be returned with three recent testimonials to, the Chief Clinical Tuberculosis Officer, 44a, Broad Street Birmingham, before June 13th.

Council House, Birmingham. T. H. C. WILTSHIRE, Town Clerk.

Chesterfield and North Derbyshire Royal Hospital.

(190 Surgical and Medical Beds.)

CASUALTY OFFICER (DEPUTY RESIDENT SURGICAL OFFICER).

OPEN APPOINTMENT.

Applications are invited from fully qualified men for the above post. The appointment is for six months. Candidates must have held previous Hospital appointments.

Duties include House Surgeon to the Ear, Nose, and Throat Department.

Salary at the rate of £200 per annum, with board, apartments, and laundry.

Applications, stating age, together with copies of three recent testimonials, to be sent to the undersigned.

May 19th, 1931. G. SUNNUCK, Supt. & Secretary.

Metropolitan Borough of SOUTHWARK.

APPOINTMENT OF MEDICAL OFFICER OF HEALTH.

The Council invite applications for the appointment of a male Medical Officer of Health, at a minimum commencing salary of £1,200 per annum, such remuneration to be inclusive of all emoluments, payments, and fees which he may receive in respect of appointments and duties devolving upon him in respect of any office which he may hold by reason or in consequence of his being Medical Officer of Health.

Candidates must hold the qualifications prescribed by the Sanitary Officers Order, 1926.

The officer appointed will be required to devote his whole time to the duties of the office, and will not be allowed to engage in private practice.

The duties to be performed are those prescribed by the Sanitary Officers Order, 1926, dated May 27th, 1926, together with any duties which may from time to time devolve on a Medical Officer of Health of a Metropolitan Borough by virtue of any present or future Act of Parliament or Orders or Regulations of the Minister of Health, subject to such variations in administration as the Council may from time to time direct. The duties will include the general supervision of the Tuberculosis Dispensary, the Municipal Creche and Maternity and Child Welfare Centres, and the officer appointed will also act as Port Medical Officer and Certifying Officer in connection with the export of meat foods.

The officer appointed will hold office subject to the standing orders of the Council, and the appointment will be subject to the approval of the Minister of Health; to the provisions of the Shoreditch and Other Metropolitan Borough Councils (Superannuation) Act, 1922, as amended; and to the passing of the required medical examination.

Canvassing of members of the Council, directly or indirectly, will be regarded as a disqualification.

Forms of application may be obtained from the Town Clerk on sending a stamped addressed foolscap envelope.

Applications, accompanied by copies of three recent testimonials, addressed to the Town Clerk, and endorsed "Medical Officer of Health," must be received not later than noon on Monday, June 8th.

D. T. GRIFFITHS, Town Clerk.

Southwark Town Hall, Walworth Road, S.E.17.

Telephone: Mayfair {1782 1783

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION have every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the **British Medical Bureau** is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the **British Medical Bureau.** Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence. Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUMTENENTS.

Assistants and Locumtenents can be secured at short notice. It is the foremost aim of the **British Medical Bureau** to ensure that only the most **Trustworthy and Reliable** Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the **British Medical Bureau.** A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The **British Medical Bureau** has its own staff of fully qualified Accountants wholly engaged on medical work—i.e., Investigation of Practices for purchasers, Income Tax, Auditing Books & Accounts, etc.

PARTNERSHIP.—HOME COUNTY.—Within 40 miles.—In a small country town, in very pleasant district, the third share, with increase later, of an old-established mixed-class Practice offering good scope. Cash receipts average over £3,000 p.a., including panel nearly 1,700 and appts. Good house, with 3/4 of an acre of garden, tennis court, etc. Rent on lease £65 p.a. Premium £1,700. Ingoing partner should be about 30, English or Scotch, and pref. married.
17. WITHIN 30 MILES OF LONDON.—In a delightful residential district (well populated and growing rapidly), a small PRACTICE, producing last year £406, including panel of 300, and capable of considerable development. Very good residence (suitable for resident patients) in about 2 acres of ground. Price, freehold, £4,000. Mortgage arranged. Premium £400. Excellent schools, good society, and sport.
18. FAVOURITE COAST TOWN.—Old-established good middle and better-class PRACTICE, producing over £1,800 p.a. Selected panel of under 400. Fees 3/6 to 10/6. Very little midwifery. Commodious house, with 2 reception, 6 bedrooms, etc. large garden. Freehold for sale. Premium £3,000.
19. SOUTH OF ENGLAND.—Pleasant Town near sea coast.—Very old-established PRACTICE (partly Surgical), averaging over £2,400 p.a. (last year £2,516), including panel of 500. Centrally situated house. Price for Practice and house £5,000. Successor should also have some knowledge of Eye, Ear, Nose, and Throat work.
20. HOME COUNTIES.—Within 40 minutes' run of London.—Old-established mixed-class and increasing PRACTICE, situated in small town with pleasant surroundings. Cash receipts average £1,725 p.a., including appt. £70 and panel 1,000. House with good accommodation and small garden. Price for freehold £2,500. Premium 1½ years' purchase. Educational facilities.
21. PARTNERSHIP.—MIDLANDS.—Prosperous Town within 80 miles of London.—A one-third or five-twelfths share is for disposal owing to the retirement of the second of three partners in an exceptionally sound mixed-class Practice. Average gross cash receipts £3,300 p.a., including panel of 1,000. Fees 2/6 to 25/-, medicine extra. Premium only 1½ years' purchase for quick sale, owing ill health.
22. SOUTH AFRICA.—Within 8 hours of Durban.—Rapidly increasing PRACTICE in very pretty township near sea coast, producing last financial year over £1,700, including appt. £120. Practically all fees, which are good, are paid in cash. Opposition negligible. Bungalow residence in about one acre of ground. Rent £84 on lease. Premium £1,500, to include furniture, drugs, instruments, and motor car (£1,325 without latter), payable £1,000 down and balance by easy instalments. Excellent climate and sport.
23. NORTH WALES.—PARTNERSHIP.—A one-third share is offered in a good mixed-class Practice producing over £1,700 p.a., including panel of 470 and appts. of about £100 p.a. Fees 3/6 to 21/-. Purchaser, if bachelor, could reside with Vendor. Good sport and schools. Premium 2 years' purchase.
24. SURREY.—Increasing residential district, with good train service to town.—Well-established good general PRACTICE, offering Surgical scope. Gross cash receipts for last 12 months nearly £3,200, with panel of about 900. Visits 5/- to 21/-. Suitable house, with 3 reception, 7 bedrooms, etc. Can be bought or rented on lease. Premium 1½ years' purchase.
25. SOUTH CORNWALL.—Near Sea.—Well-established PRACTICE producing about £700 p.a., including panel of over 600. Fees 5/- to 21/-. Suitable house, with 3 reception, 5 bedrooms, etc. Rent on lease £50 p.a. Good sport and mild climate. Premium only 1 year's purchase. Ill-health reason of sale.
26. LONDON, SOUTH-EAST. — Woman Doctor's PRACTICE, producing £560 immediate past 12 months. Panel of 152. Fees 2/6 to 21/-. Suitable flat can be rented at £50 p.a. Premium £650, or near offer. Very good scope for increase.
27. NORTH LINCS.—COAST TOWN.—Old-established PRACTICE, producing last year nearly £2,900 p.a., including panel of 1,700. Fees 3/6 to 21/-. Practically unopposed. Good modern house, with special professional rooms. Nice garden. Garage. Freehold for sale, part on mortgage. Good sport and schools within reach. Premium 1½ years' purchase.
28. NORTH OF ENGLAND.—GOOD TOWN.—A one-third share is offered in a very sound PRACTICE averaging about £5,000 p.a. Ingoing partner must be well qualified, not over 35, and interested in medicine. Suitable house available. Premium 2 years' purchase.
29. NEAR HEREFORDSHIRE BORDER.—A one-third to one-half share in a well-established good-class non-dispensing PRACTICE, producing about £1,800 p.a. Panel of over 500. Good house can be rented at £60 p.a. Sport of all kinds. Premium 1½ years' purchase, part by instalments. Welsh not necessary.
30. CHESHIRE.—COAST TOWN, within reach of Liverpool.—Well-established PRACTICE, averaging over £1,200 p.a., including panel of 780. Fees from 3/6. Mid. 2 to 5 gns. Double-fronted house, with 3 reception, 4 bedrooms, etc. Price for freehold £1,200, £800 on mortgage. Premium £1,100 for quick sale.
31. SOUTH-WESTERN COUNTY. — Hospital Town. — Good mixed-class PRACTICE, averaging £839 p.a., including small panel of 140, and appt. worth £40 p.a. Visits 5/- to 10/6. Not much midwifery. House, with 3 reception, 4 bedrooms, etc. Garden. Garage. Price for freehold £1,600, half on mortgage. Very good schools and sport. Premium £1,300.
32. MIDLANDS.—COUNTY TOWN.—Old established better class PRACTICE, averaging £795 p.a. and offering good scope. Panel 500 Fees 5/- upwards. Well situated house with good garden, with reception, 4 bedrooms, etc. Separate Surgery. Rent on lease £11 p.a. Premium 1¼ years' purchase.

Full Schedule of Terms and Conditions will be forwarded on application.

Valentine's Meat-Juice

In **Typhoid Fever, Diarrhoea and Cholera Infantum,** when it is **Essential** to **Sustain** the patient **without irritating** the **Digestive Organs,** the **Ease** of **Assimilation** and **Power** of **Valentine's Meat-Juice** to **Restore** and **Strengthen** has been demonstrated in Hospital and Private Practice.

THE quickness and power with which VALENTINE'S MEAT-JUICE acts, the manner in which it adapts itself to and quiets the irritable stomach, its agreeable taste, ease of administration and entire assimilation recommend it to physician and patient.

Physicians are invited to send for brochures containing clinical reports.

For sale by European and American Chemists and Druggists.

VALENTINE'S MEAT-JUICE COMPANY,

Richmond, Virginia, U. S. A.

WB 302

SAVED BABY'S LIFE!

PORTE'S CAESAREAN OPERATION

In 'The Scottish Nurse' for January 1931 appeared an article by a Scottish State Registered Nurse describing an exceedingly severe operation—*Porte's Caesarean Section*—which she underwent in Malta at the hands of a well-known surgeon.

Twenty-four hours after the second stage of labour had begun it was discovered that delivery was impossible. The womb had become septic and the Porte Caesarean was performed, the baby being safely extracted.

The condition of the mother was then highly critical, and the baby had to be revived by artificial respiration. For a week after birth she weighed only five pounds. The mother, despite intense pain and weakness, endeavoured to nurse her, but as progress appeared stationary she was put on alternate feeds of Cow & Gate Full Cream Milk Food and Breast.

From then onwards she made rapid progress and at four months the mother weaned her altogether.

Now eight months old, the child is the picture of contentment and happiness and weighs over 17 pounds.

COW & GATE MILK FOOD

has saved more baby lives than any other preparation in the world

"The best milk for babies, when natural feeding fails."

Cow & Gate MilkFood

COW & GATE LTD, GUILDFORD SURREY

AMENORRHEA

The most successful treatment is that which supplies the endocrine stimulus to menstruation

Prescribe

HORMOTONE
BRAND

The clinical use of Hormotone has now extended over a long period of years and its success has been thoroughly demonstrated. In scanty menstruation or actual suppression of the menses it is an effective therapeutic agent.

Dose: 1 or 2 tablets three times daily.

Bottles of 100 tablets.

Medisoap

MIDGLEY'S MEDICATED SOAP

Medisoap Therapy to-day forms an important part of the standard treatment prescribed by leading dermatologists. Skin medication by means of Medisoaps is free from the discomforts of ointments, a fact which is of marked importance in scalp diseases for which Medisoaps are ideal.

A PRESCRIBER'S INDEX

relative to the comprehensive range of Medisoaps is available to members of the medical profession on application to:—

EVANS' BIOLOGICAL INSTITUTE, HIGHER RUNCORN, CHESHIRE

Medisoaps are stocked by pharmacists in all parts of the country.

Sole Makers:

CHARLES MIDGLEY, LTD. *Medicated Soap Specialists* MANCHESTER

Associated with EVANS SONS LESCHER & WEBB, LTD., Liverpool and London.

The Issue of the BRITISH MEDICAL JOURNAL is this week 43,500 copies.

NEW (2nd) EDITION

CECIL'S TEXT-BOOK OF MEDICINE

NEW (2nd) EDITION

READ THIS REVIEW

"The second edition, issued only four years after the first, of this well-known text-book, may almost be described as a new work. It has been re-set throughout, and largely re-written. The first essential in a text-book of modern medicine is that, as a work of reference, it shall contain everything; the next, that sound judgment should be exercised in presenting from the collection of facts a clear picture of the disease under discussion. In these two main features, the success of the authors has been indeed great. While a certain amount of unevenness is unavoidable amongst so many collaborators, some articles being better than others, the general level is extraordinarily high, and to review a work like this by singling out the treatment of any particular disease would savour somewhat of 'cheapness.' Judging the work as a whole, therefore, we have no hesitation in describing it as the best large text-book on medicine that has been produced in the English language for some time past, and in commending it for purchase not only by the student, but by the consultant also. The writers are for the most part teachers in American Universities and the larger hospitals, though contributions from eminent teachers and research workers of other nationalities have been included. The skill with which the separate essays have been combined into a coherent and readable whole excites our admiration. The paper and type are both excellent. Finally, the price is only 40s."—MEDICAL PRESS AND CIRCULAR.

Octavo of 1,592 pages, illustrated. By 135 American authorities. Edited by RUSSELL L. CECIL, M.D., Assistant Professor of Clinical Medicine, Cornell Medical School. Cloth, 40s. net.

TREATMENT IN GENERAL PRACTICE

By HARRY BECKMAN, M.D., Professor of Pharmacology, Marquette University, Milwaukee. Octavo of 899 pages. Cloth, 45s. net.

"This book or its equivalent should be in the hands of every physician, and we have not yet come across its equivalent."—THE LANCET.

NUTRITION AND DIET

By JAMES S. MCLESTER, M.D., Professor of Medicine at the University of Alabama. New (2nd) Edition. Octavo of 891 pages. Cloth, 36s. net.

"Provides an excellent and well-balanced exposition of the subject of Dietetics. In it justice is done to both the theoretical and practical aspects of nutrition and its value as a work of reference is enhanced by the carefully selected bibliographies presented at the end of each chapter."—EDINBURGH MEDICAL JOURNAL.

DISEASES OF THE SKIN

By GEORGE C. ANDREWS, A.B., M.D., Associate Professor of Dermatology, College of Physicians and Surgeons, Columbia University. Octavo of 1,091 pages, with 988 illustrations. Cloth, 55s. net.

"The whole volume is excellently got up, and, considering the amount of matter contained in it, remains moderate in size and easy to handle. We commend it with confidence both to general practitioners and specialists."—BRITISH MEDICAL JOURNAL.

EXAMINATION OF PATIENTS

By NELLIS B. FOSTER, M.D., Associate Professor of Medicine, Cornell University College of Medicine. Octavo of 392 pages, with 83 illustrations. Second Edition. Cloth, 21s. net.

"In this second edition the author has, in response to repeated requests, treated the subject of differential diagnosis in the same concise manner as in his previous description of the methods of examination. The style is attractive and carries the reader pleasantly along. . . . As a whole the work fully justifies its obvious popularity."—BRITISH MEDICAL JOURNAL.

HISTORY OF MEDICINE

By FIELDING H. GARRISON, M.D., Lieutenant-Colonel, Medical Corps, U.S. Army, Surgeon-General's Office, Washington, D.C. Octavo of 996 pages, with numerous portraits and other pictures. Fourth Edition. Cloth, 55s. net.

"The most readable, and in some respects the most valuable of medical histories. The record of progress is enhanced throughout by touches of human interest. The author is never dull. . . . We congratulate him on having produced a fascinating volume, which, while full of solid learning, can, unlike most histories of medicine, be read from end to end without a yawn."—BRITISH MEDICAL JOURNAL.

TEXT-BOOK OF GYNAECOLOGY

By ARTHUR H. CURTIS, M.D., Professor and Head of the Department of Obstetrics and Gynaecology, Northwestern University Medical School. Octavo of 375 pages, with 224 illustrations, 5 in colours. Cloth, 24s. net.

"This delightful book conveys to the reader exactly what is intended, that is, a personal record of personal experience and an exposition of all that the author believes is vital in gynaecology. The illustrations are excellent. I have read with pleasure every page . . . and recommend the appeal and distinction of this volume."—INDIAN MEDICAL GAZETTE.

D. APPLETON & CO., 34, BEDFORD ST., LONDON

LIPPINCOTT BOOKS

OPERATIVE SURGERY
General and Special Considerations

By Dr. MARTIN KIRSCHNER, Professor of Surgery and Director of the Surgical Clinic at the University of Tubingen, Germany.

Authorised translation by I. S. RAVDIN, B.S., M.D. With 746 Illustrations. Mostly Coloured. 50s.
Ready June.

The presentation of the first English edition of Kirschner's work is offered without apologies. A work so skilfully and beautifully illustrated fills a definite need in surgical literature. It is a book that will not only appeal to the surgeon, but also to the practitioner, who must do some of the minor surgery which is shown in this beautiful Colour Surgery.

Monographs on Surgical Pathology.

SURGICAL PATHOLOGY OF THE DISEASES OF BONES

By ARTHUR E. HERTZLER, M.D. 211 Illustrations. 21s.
Other volumes to follow. *Ready June.*

There is no work which treats in a comprehensive manner with the pathology of the diseases of bones, and this book is the result of thirty years of medical teaching by the author.

HUMAN ANATOMY
Including Structure and Development and Practical Considerations

By GEORGE A. PIERSOL, M.D., and others. Ninth Edition. 1,734 Illus., 541 in Colour. 45s.
The Latest, Best, and Most Richly Illustrated Anatomy Published.

CANCER
IN FOUR PARTS

Part I. CANCER IN ITS GENERAL RELATIONS.
Part II. CANCER RESEARCH.
Part III. REGIONAL CANCER.
Part IV. RADIUM AND RONTGEN RAY THERAPY.

International Contributions to the Study of Cancer. In Honour of JAMES EWING.

Edited by FRANK E. ADAIR, M.D., F.A.C.S. 168 Illustrations. 484 pages. Edition limited. 45s.

Fifty-four articles by world authorities on the subjects of Surgery, Radiology, Pathology, and Cancer Research.

FRACTURES AND DISLOCATIONS:
Treatment and After-Care. 2nd Ed. Revised

By PHILIP D. WILSON, M.D., and WILLIAM A. COCHRANE, M.D. 45s.

This modern treatise is illustrated with 1,029 pictures, and presents all the latest developments in treating fractures and dislocations.

"We can safely recommend this book as one of the best and most up-to-date guides for the general practitioner, as well as for the expert surgeon and the student."—BRITISH MEDICAL JOURN.

LIPPINCOTT'S QUICK REFERENCE BOOK for MEDICINE and SURGERY

By GEORGE E. REHBERGER, A.B., M.D. Seventh Edition. 3 Folding Manikins. 33 Coloured Plates. 151 Illustrations. 65s.
Covers the whole field of practical medicine excepting Psychiatry.

Medical Catalogue sent post free on application.

J. B. LIPPINCOTT COMPANY, 16, John Street, Adelphi, London, W.C.2.

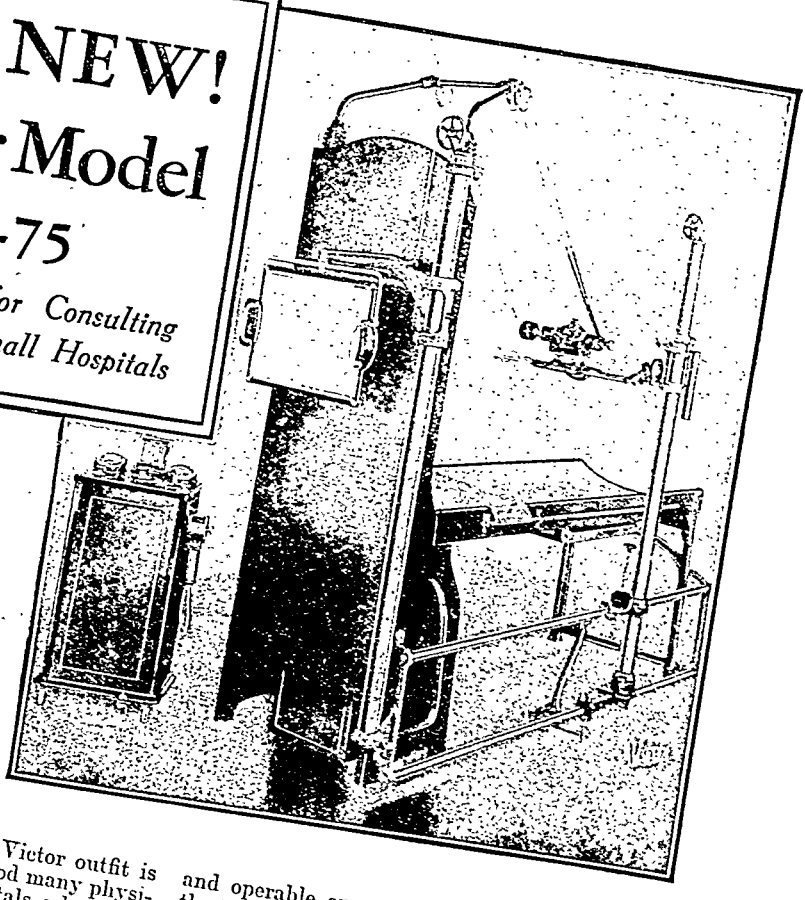
IT'S NEW! Victor Model 17-75

X-ray Unit for Consulting Rooms and Small Hospitals



THIS newly designed Victor outfit is bound to interest a good many physicians and smaller hospitals who want a compact, thoroughly efficient X-ray apparatus, offering a practical range of service, at a price commensurate with the volume of work they will do with it.

This Victor Model 17-75 is, as may be seen in the illustration, a complete and self-contained diagnostic X-ray apparatus, and requires a comparatively small floor space, considering the range of service that it offers.

With this outfit you are prepared to do horizontal radiography, with the curved type Potter-Bucky diaphragm permanently mounted underneath the table top and operable over the entire length of the table; also vertical fluoroscopy at the foot of the table, by simply bringing the tube stand into position along the floor rail.

No overhead wiring to install, as the transformer is mounted on the floor, the high voltage current being conducted through insulated posts to the overhead reels and to the tube.

The ease of operation and refinement of control insure a consistently high quality of radiographs of real diagnostic value. Remember, this outfit bears the Victor trade mark—you know what that implies.

Write for further particulars.

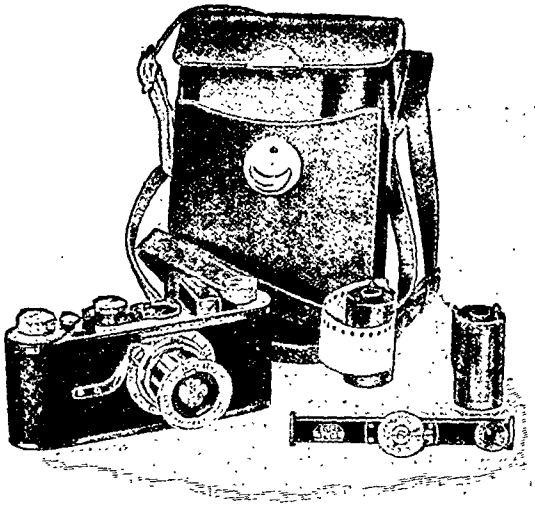
Leitz

LEICA CAMERA



36 Exposures with one loading.

Ready in an instant, owing to film winding automatically when re-setting shutter. Double exposures impossible.

Capped Focal-Plane Shutter for time and instantaneous exposures to 1/500 sec.

THE CAMERA of DISTINCTION

Small Negatives — Large Pictures.

Leitz "Elmar" *f*/3·5 anastigmatic lens, highly corrected, and giving the sharpest negatives, making enlargements possible to an almost unlimited magnification.

Enormous depth of focus, due to short focal length and special computation of the lens.

The LEICA is a universal camera, equally suitable for studio, home interiors, landscapes, sports records, clinical photography, etc.

A Doctor writes:—"I have had many cameras, but until I had the LEICA I never took a good photograph. The amazing depth of focus makes the Leica specially suitable for clinical work. . . . I now take my clinical photography with the minimum expenditure of time."

HEWLETT'S

"Complete G.P." Bag

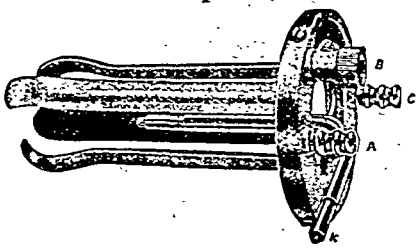
This bag is so arranged that every item is immediately visible and accessible the moment the lid is lifted. The front of the bag need only be let down rarely to get at the compartment holding the emergency dressing, etc. The large central space is to hold a folding stethoscope, and room is left for further instruments such as sphygmomanometer, etc.

PRICE, with Instruments and Fittings, in Black or Brown Cowhide, lined with Rexine £7 0 0
PRICE, in Black Rexine instead of Leather £6 10 0

A fully illustrated pamphlet, with suggested list of drugs for inclusion in the bag, will be sent on application.

BARON'S VAGINASCOPE (Patent No. 330,629)

A Compact Self-retaining and Illuminated Speculum



UNIFORM DILATATION OF VAGINA. By loosening screw-knob 'B' and then placing the thumb in peg 'A' and the forefinger on 'B,' a single grip effects a simultaneous parallel and outward movement of the four blades, resulting in a quick dilatation of the vagina. Sufficient dilatation having been obtained the screw-knob is tightened, thus locking the instrument in the open position as illustrated.

PRICE, in Leatherette Case, with battery and flex, £3 17 6

Illustrated pamphlet giving full particulars sent on application.

Introduced and manufactured only by

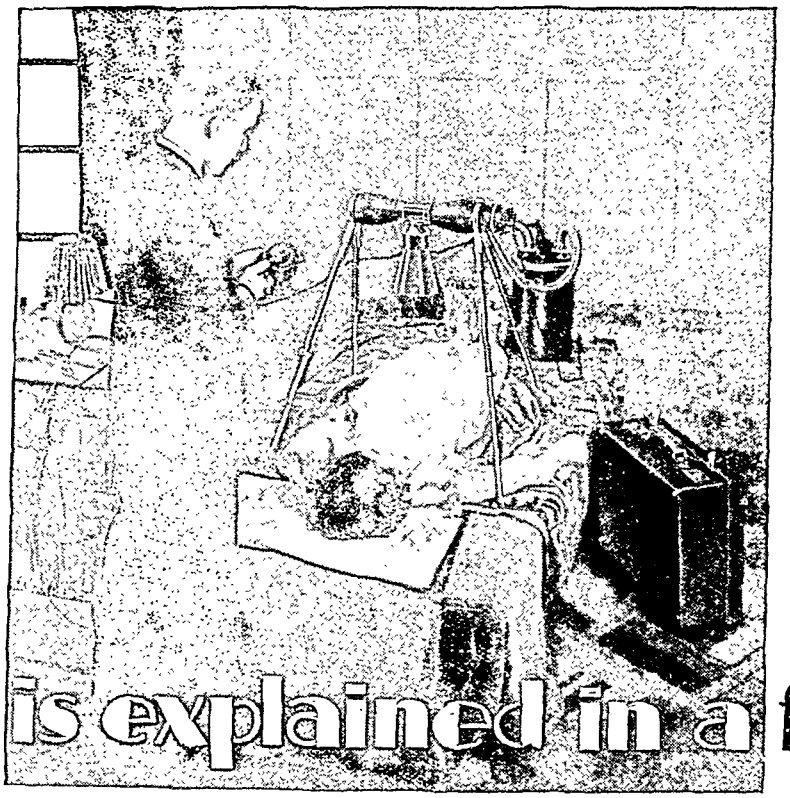
LEICESTER. LONDON. DUBLIN. LEEDS. BRADFORD.

THE "METALIX-PORTABLE"



is explained in a few words

The illustration shows the "Metalix-Portable" being used in a patient's home to make a radiogram of the pelvis—on a full size (12" × 15") film. The outfit is connected to an electric light socket, the back of the time-switch consulted to obtain the correct exposure time, the button depressed, and an excellent picture assured.

Should the patient touch any part of the outfit during the exposure no harm could possibly result, whilst the doctor is equally well protected against both high tension and unwanted radiation.

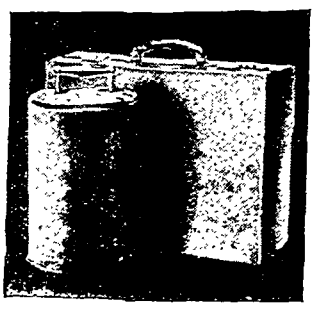
With equal facility and safety, visual screen examinations can be made, the screen image often being sufficient for the purpose of diagnosis.

The "Metalix-Portable" is no longer new; for over two years a steadily increasing number of general practitioners have become "Metalix-Portable" users and enthusiasts. It is now a recognised item of equipment of the progressive medical man.

A publication containing full facts about the "Metalix-Portable," with specimen radiograms and convincing medical testimony, will be sent on request.

Price of complete "Metalix-Portable" outfit for operation on standard A.C. voltages, £138 . 0 . 0. For D.C. voltages £25 . 0 . 0 extra.

Packed as shown here, the "Metalix-Portable" is carried with the utmost ease.



PHILIPS METALIX-PORTABLE

You're always taking temperatures . . .

but do you ever take the temperature of your own Larder?

JUST try the experiment. Remember that over 50° for your food is just as bad as over 100° for your patient. Over 50°, bacteria multiply in food 400 times faster than at temperatures below. And, apart from the health reasons, wouldn't it be comforting to know that your food was kept cold and appetising and fresh, in a snow-white all-porcelain Frigidaire, shut away from the dirt and flies, *automatically* prevented from "going off"? Perhaps you've been promising yourself a Frigidaire—then send in the coupon to-night and see how little it costs!

Frigidaire incorporates all the conveniences and refinements that you would wish to have in your electric Refrigerator. Here are just a few of them.

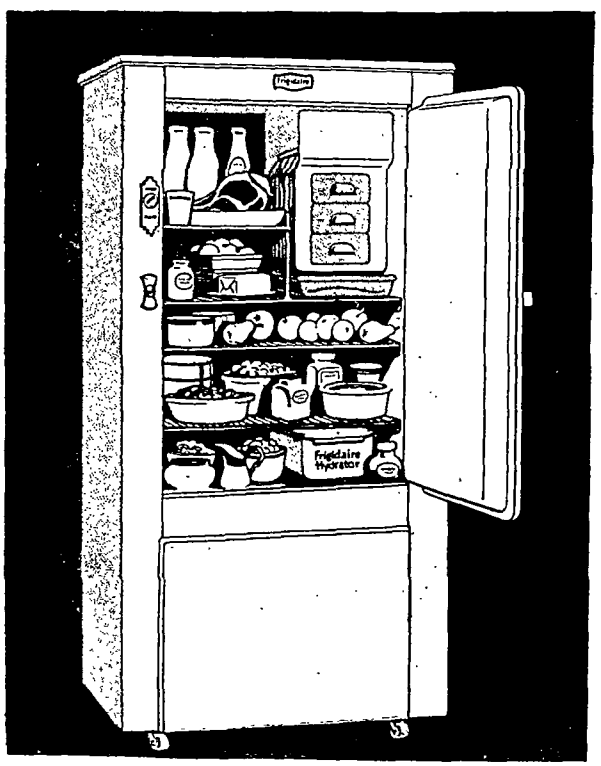
The Quickube Ice Tray, enabling single cubes, or many, or all, to be extracted at once, simply by a light pressure of the finger. No melting them out under the tap. Your cocktail ice is ready at a moment's notice. This is an exclusive Frigidaire feature.

●

The Cold Control, by which the freezing of ice cubes or any frozen delicacy can be accelerated at will.

●

The automatic feature of Frigidaire is invaluable. It cuts out the human element with its forgetfulness and consequent waste. Frigidaire maintains a dry cold that is *always* under 50°—the only safe temperature for food.



Practical flat top, makes a useful shelf.

●

The Hydrator—a *moist* cold compartment, for fresh vegetables, sandwiches, etc. Even wilted vegetables will regain their crispness here in a few hours.

●

Ease of installation. A Frigidaire only needs connection with your electric supply. No plumbing is necessary.

●

The new Frigidaire is quiet—you can't hear it start, stop or run.

Showrooms at 141, New Bond Street, London, W.1, and in all principal towns.

COUPON

FRIGIDAIRE LIMITED (*Incorporated in Canada*), Dept. BG-66, Edgware Road, The Hyde, Hendon, N.W.9

Please give me by return, without any obligation on my part,

(a) Price of Frigidaire cabinet suitable to my particular needs; or

(b) Particulars of your system of convenient deferred payments.

COOL COMFORT IN A SPENCER SUMMER SUPPORT

Sheer—Ventilative—Yet Strong

Fashioned of a specially constructed, strong material that is light in weight and *perforated*, Spencer Summer Corsets provide Firm Support as well as cool comfort for your patients.

Spencer Summer Corsets have the identical *designing* qualities that our other garments possess. Each garment is individually designed and individually made for the one woman who is to wear it. They are firmly but comfortably boned.

Spencer garments are the most economical garments you can prescribe, because they answer a woman's *style* need as well as her doctor's requirements. Thus one garment suffices for all wear. When a woman buys the ordinary kind of Surgical Support she is faced with the necessity of buying another garment for dress wear. This means two garments. Fortunately, the Spencer surgical features are *incorporated in a style garment.* In a Spencer a woman has what she wants—and what the doctor wants, too.

Thyroid Medication

A new preparation of the pioneers in endocrine therapy

The name given to Reed & Carnrick's new thyroid speciality is Thyracoids.
"Thyracoids" consist of iodothyroglobulin, standardised biologically. They can be depended upon to be of uniform strength and to represent the entire activity of desiccated thyroid.
Thyracoids may be used advantageously in all cases where thyroid medication is indicated.

Packings: Bottles of 100 $\frac{1}{12}$, $\frac{1}{4}$, 1 and 2 grain tablets
Plain or enteric coated.

Descriptive literature from Sole Distributing Agents for U.K. and Irish Free State:—

COATES & COOPER, LTD.

Thyracoids

Manufactured by REED & CARNRICK, Pioneers in Endocrine Therapy, Jersey City, NEW JERSEY.

As a restorative in convalescence and in cases of anaemia

Colloidal Iron Concentrate	83%
Pure Alcohol	6%
Sugar	10%
Flavouring	1%

That is the formula of this tonic preparation, which contains a larger percentage of assimilable iron than has hitherto been provided in either a general or colloidol form. A more rapid response may therefore be anticipated from the administration of this preparation, which is very pleasant to take and well tolerated by all patients.

Idozan has no constipating effect, it does not derange the stomach or discolour the teeth. Though incompatible with alkaline salts, it may be combined with Liq. Arsenicalis and vegetable tinctures. It is therefore very suitable for therapeutic administration, where it is desired to give large doses of iron; both as a restorative after illness and in cases of anaemia it can be prescribed either with or without additional drugs with confidence and freedom. One size only, 8-oz. bottles, 5/-.

IDOZAN HAS BEEN REGULARLY PRESCRIBED BY DOCTORS IN FIFTEEN DIFFERENT COUNTRIES

IDOZAN

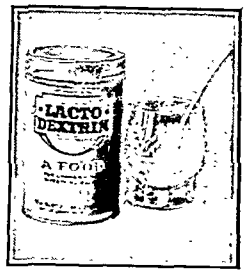
Of special service in FISSURE or HAEMORRHOIDS

"PSYLLIUM seeds when immersed in water yield a mucilaginous substance which is able to take up relatively large quantities of water to form a gelatinous mass. They become in this way a useful lubricant, while the emollient character of the mass renders it of special service in fissure or haemorrhoids."—*Lancet*, Jan. 10th, 1931.

Another preparation of importance as a laxative agent is Lacto-Dextrin—a palatable combination of lactose and dextrin for changing the intestinal flora.



Samples and literature of both these intestinal products will be sent to members of the Medical Profession on request to Coates & Cooper, Ltd., 41, Great Tower Street, London, E.C.3, Sole Distributing Agents for the United Kingdom and Irish Free State.

PSYLLA *(Psyllium Seed)*

LACTO-DEXTRIN

Products of the BATTLE CREEK FOOD CO., Mich., U.S.A.

A Distinct Advance Over Preparations of Acetyl-Salicylic Acid

Acetyl-salicylic acid possesses a notable disadvantage. Physicians have proved that it cannot be tolerated by patients suffering with a delicate stomach. Consequently, the value of this medicament in the wide field in which it is indicated is very seriously reduced.

"Alasil" completely overcomes this objection. By combining calcium acetyl-salicylate with "Alocol," unfavourable secondary action upon the stomach is prevented. This beneficial influence is undoubtedly due to the presence of "Alocol" (Colloidal Hydroxide of Aluminium), which preparation has brilliantly stood the test of practice in the treatment of hyperacidity and other ill conditions of the gastric tract. "Alasil" is therefore a triumph over acetyl-salicylic acid. It enables higher doses to be administered and maintains the patient's system under its influence for a greater length of time. Analgesic, Antipyretic, and Sedative, "Alasil" is indicated in all cases where acetyl-salicylic acid has been used heretofore.

A supply for clinical trial with full descriptive literature sent free on request.

OVER 900 BRANCHES IN GREAT BRITAIN

Modern diets often lack minerals

To-day, authorities are stressing the importance of the essential mineral salts. In addition to building sturdy bones, and blood rich in hemoglobin, these mineral elements aid metabolism and contribute to nervous stability.

Yet many modern diets cannot be depended upon to furnish the proper quota of minerals, and therefore millions of people suffer from the effects of demineralization. Cooking destroys a variable amount of the mineral value of foods—in some instances as high as 76 per cent.

To correct this loss and to remedy demineralization—with its attendant symptoms of nerve fag, neurasthenia, lowered vitality and loss of energy—a tonic rich in mineral salts is needed.

Compound Syrup of Hypophosphites "Fellows" contains the mineral salts of sodium, calcium, potassium, manganese, iron and phosphorus, together with the added metabolic stimulants—strychnine and quinine. Sixty years of clinical experience the world over testify to its value as a tonic.

Suggested dosage: A teaspoonful in half a glassful of water three or four times daily.

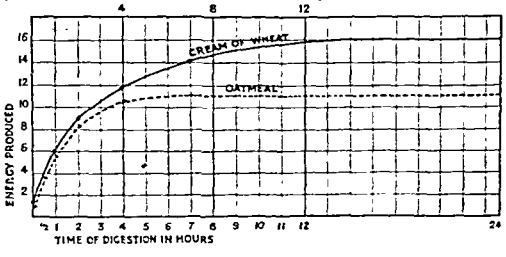
THE BRITISH DRUG HOUSES LTD. LONDON N-1

LE/GS/23

"Cream of Wheat" is prominent on the diet sheets of leading British pediatrists

Great biochemical institute proves it more digestible than oatmeal and productive of one-and-a-half times as much energy.



When the digestion of "Cream of Wheat" was complete it was found that its sugar yield was 50% greater than that of oatmeal; in other words, that it was productive of 1½ times as much energy. Moreover, it will be seen that for 4 hours after the digestion of oatmeal was almost at a standstill, the digestion of "Cream of Wheat" was continuing at a scarcely diminished rate.

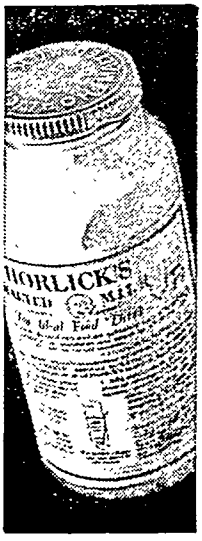
From a study of text-books and monographs on infant feeding published in the past few years, it is evident that "Cream of Wheat" is becoming increasingly popular among pediatrists as a first starch food for infants. This preference, based on clinical experience, has recently been justified by experiments conducted in the laboratories of a leading biochemical institute. These experiments, as the accompanying graph shows, conclusively prove the superiority of "Cream of Wheat" over oatmeal.

Prepared and packed under rigorous inspection and the most hygienic conditions—

"Cream of Wheat" is made entirely from the granulated endosperm of the best wheat and contains 72% starch.

It is purified and re-purified under intense heat and rigorously inspected at every stage before being finally triple wrapped in cartons. Free from husk, it can be safely given even as early as the third month; it is invaluable wherever there is a tendency to fat intolerance owing to the thorough hydrolysis and metabolization which it renders possible; and is a useful food in the post-operative period. A professional card will bring you fuller details of the above tests, and a sample of this cereal.—Dept. W.5, Fassett & Johnson, Ltd., 86, Clerkenwell Road, London, E.C.1.

HORLICK'S MALTED MILK, a modified milk food, is full-cream cows' milk combined with the nutritive extracts of malted barley and wheat, evaporated to dryness at a low temperature in vacuo by the special HORLICK process. *HORLICK'S MALTED MILK has proved of value in infant feeding, disease of the alimentary canal, myocardial disease, fevers, during pregnancy and lactation, and in all conditions where it is essential that the patient should be given a



palatable and agreeable diet, and one affording a maximum of nourishment with a minimum of digestive effort. *The characteristics of easy digestibility and absorption, and a high degree of assimilation, which have enabled HORLICK'S MALTED MILK to be confidently recommended by the Medical Profession for nearly fifty years, cannot be obtained from a blend of cereals and dried milk. *HORLICK'S MALTED MILK contains no free starch or cane sugar.

THIS NAME—

GUARANTEES SAFETY

The name MARSHALL'S guarantees purity, efficiency, uniformity in every bottle of Lysol you purchase. There are other Lysols to be had, but MARSHALL'S is the only Lysol made to the original formula.

MARSHALL'S is better because it allows a greater margin of safety. In the correct dilution its bactericidal power is certain, yet it is harmless to the most delicate tissue. MARSHALL'S Lysol is the most widely used antiseptic for Obstetrics, Gynaecology, etc., because it is ideal for these purposes.

ONLY THE PUREST INGREDIENTS

All the ingredients of MARSHALL'S Lysol have to conform to the most rigid specification. Every stage of manufacture is subject to strict and constant supervision and analysis to ensure a product worthy of your recommendation.

Doctors, Nurses and Hospitals all over the world put their faith in MARSHALL'S—a faith that has been justified by 40 years of unfailing efficiency and uniformity.

Sample free on request to members of the medical and nursing professions.

LYSOL LTD., Dept. K 18, RAYNES PARK, S.W.20.

a Physician writes re....

Over 12,000 Doctors now obtain their own supplies of Ty.phoo tea from us.

DYSPEPSIA AFTER TEA

Copy of M.1190.

"For several months this year I was troubled with dyspepsia, and I found that my habit of drinking about six cups of ordinary tea per diem was responsible for the trouble.

I decided to drink 'Ty.phoo' tea, and since using it I have had absolutely no dyspepsia in spite of the fact that I drink as much, if not more, than I used to."

C——, Esq., M.B., D.P.H.

WE print here one of the many Medical testimonials we are constantly receiving as to the undoubted value to dyspeptics of the pure natural "leaf-edge" tea in which we specialise.

Ask Sumner's Ty.phoo Tea Ltd., Dept. B/MD, Birmingham,

for a free sample of "Ty.phoo" natural leaf-edge tea and full particulars.

TRY "Ty·phoo" TEA in Indigestion.

Kaylene

for the treatment of acute intestinal infections, ptomaine and other forms of food poisoning, and all diarrhoeal conditions. It acts by adsorption and is the true antidote to bacterial toxins and toxalbumins in contaminated food.

The action is speedy and certain.

Kaylene-ol

An emulsoid of the toxin adsorbent Kaylene combined with a highly viscous Liquid Paraffin. The latter counteracts the consolidating effect of the Kaylene. This preparation may be prescribed with confidence for those conditions in which toxaemia is associated with constipation. **It actively prevents the absorption of toxins** and completely puts an end to the fouling of the lymphatics and the blood.

Samples and "adsorption" literature obtainable on request to the Manufacturers:

Specially indicated for cases of Constipation, Indigestion, Malnutrition, Obesity and Diabetes

Though most physicians realise the general benefit to health which follows the use of Ryvita Crispbread in the place of ordinary bread in the daily dietary, its particular advantages for certain special conditions are not always appreciated. The following notes will therefore be of interest to those who have not yet experienced its use in such circumstances.

CONSTIPATION. Apart from the mechanical action which follows on its freedom from moisture and its retention of the natural roughage of the grain, Ryvita contains all the special laxative properties of Rye, due it is believed largely to its richness in Vitamin B and the salts of lime and iron and phytates. The stimulative effect upon intestinal movements of Vitamin B is confirmed by much recent dietetic research.

MALNUTRITION. Owing to the extreme ease of its digestion, coupled with its high value in proteins and carbohydrates, Ryvita is a great help to the physician in promoting the proper metabolism which alone can end malnutrition. Its delicious and appetising nature is a valued adjunct. Patients should not regard it as a medicated bread but as a better and more nutritive form of bread. They will find it delightful with butter, with marmalade or jam or cheese, or indeed in any fashion in which they have been in the habit of eating ordinary bread.

INDIGESTION. Here again the value of Ryvita is both physical and chemical. Its crisp, dry character compels proper mastication and ensures thorough insalivation. Thus Ryvita, besides being itself easily digested, promotes the digestion of other foods also. As to its chemical nature, its exceedingly high percentage of soluble carbohydrates greatly lightens the burden of starch digestion.

OBESITY. Whereas ordinary bread even of the so-called "wholemeal" variety is marked by a very high percentage of moisture and exceedingly low calorie value, Ryvita contains under 10 per cent. of moisture and a value in calories of some 1,662 calories per lb. Thus Ryvita contains all the value without the disadvantage of excessive bulk. It will be seen, therefore, that for cases of obesity, Ryvita, which the "Lancet" describes as "a concentrated form of food," is very definitely indicated and many cases have been reported where its use brought excellent results.

DIABETES. In many cases of Diabetes, the comparatively small quantity of unconverted starch in Ryvita makes its addition to the diet very valuable. It should, however, be given with regard to the starch tolerance of each particular case, and we shall be glad to supply details of its analysis on request.

BETTER MILK FOR BABIES

FACTS ABOUT
LACTOGEN

Vitamins and Minerals

To fulfil the requirements of the rapidly growing child an adequate supply of vitamins and mineral salts must be provided.

Milk furnishes a sufficiency of these essentials, and in Lactogen their complete conservation is effected.

For the final desiccation of the modified fresh milk the roller process is employed. The heat applied is thus reduced to a minimum and the exposure confined to a matter of seconds.

Lactogen provides a full complement of mineral salts in organic combination, together with the adequate vitamin allowance. It is a complete and balanced diet furnishing the infant with every essential necessary for good health and normal development.

Lactogen is neither a new nor untried product. First introduced in Australia, it has for many years enjoyed a large sale in overseas countries.

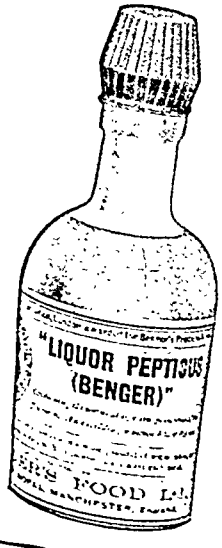
ESSENCE of RENNET
CONCENTRATED (BENGER).
(Curdling Fluid)

Originally prepared at the request of a prominent physician, this highly concentrated essence is of especial value in Infant and Invalid Feeding. As it is concentrated it is much quicker in its effect than most other preparations of Rennet. Whey prepared with Benger's Essence of Rennet is of the greatest value in the treatment of diarrhœa, vomiting, etc.; it can be employed with confidence and will yield good results. Junket can be made more quickly and at a lower cost by using Benger's Essence of Rennet than by any other method.

In 1/- and 1/9 bottles.
Larger sizes for hospitals, etc., use.



LIQUOR PEPTICUS
(BENGER).

"A digestive agent of extraordinary power."
Sir William Roberts, M.B., F.R.S.

Benger's Liquor Pepticus, is a concentrated and highly active fluid pepsin in acid solution which acts particularly upon meat, eggs and other proteid foods.

The best results from the use of Liquor Pepticus are obtained when it is prescribed alone. Should the prescriber wish to combine medicaments of a tonic nature, it will be recollected that those which are free from astringency and alkalinity should be selected.

In 4, 8 and 16-oz. bottles.
Prices: 3/6, 6/6 and 12/6.

CAPITAL BEARING THE MONOGRAM OF THEODORIC THE GOTH, THE EARLIEST OF THE GREAT MEDIÆVAL RULERS AND AN OUTSTANDING TEUTONIC PIONEER.—The letters and edicts of Theodoric the Great reveal the wise and thoughtful spirit of the ruler, who, by welding the Græco-Roman culture and the robust Teuton character of his subjects, produced a long period of settled government in Italy. The following are extracts from his letters: "Italy ought to enjoy her own products and it is monstrous that anything which she produces should be wanting to her own children. Therefore, let no lard be exported to foreign parts, but let it, by God's grace, be all kept for consumption at home." In granting immunity from taxes for districts ravaged by war, he says: "We wish promptly to relieve all the distresses of our subjects and we therefore at once announce to you that the districts ravaged by the incursions of the enemy will not be called upon to pay tribute at the Fourth Indiction (Sept. 510 to Aug. 511 A.D.). The capital here reproduced is from Ravenna where the Ostrogoths exercised considerable artistic influence.

LECTURE II

(With Special Coloured Plates)

COMPLICATIONS AND FATAL CASES

In this series about 40 per cent. of the patients were known to have the biliary tract affected. There were twelve fatal cases in the series, and of these only one followed removal of the spleen; in contrast, there were fourteen patients treated by splenectomy, only one of whom died, and this one from surgical mishap. Of the twelve fatal cases, no fewer than eight died of haemolytic anaemia, two died of cholangitis, complicated in both instances by anaemia, and two of intercurrent disease. Haemolytic anaemia caused death at such varying ages as 3½, 13, 30, 43, 56; the symptoms in some cases appeared unexpectedly and severely, and in others they arose more gradually. The two cases of fatal cholangitis were both complicated by severe anaemia, so that ten out of the twelve deaths were associated with the latter condition. There is, then, a proneness for a severe and destructive anaemia to develop during the life of a patient suffering from acholuric jaundice. A study of the fatal cases in this series makes it clear that most of these deaths were avoidable.

The cases of the Tope children, described in Lecture I, show how haemolytic crises may arise. The cases of Labourne and Bass, also described in Lecture I, show how haemolytic anaemia may recur and finally kill the patients at the ages of 53 and 44, whereas the jaundice of early years may almost have been forgotten.

TREATMENT

The results of splenectomy have been strikingly good; this is an important point. The jaundice disappears quickly, and the red blood count commonly approaches the normal after a short interval. Even with the severe anaemias the recovery is rapid and permanent, and the patients are thenceforth healthy.

The ages of the patients operated on varied, the youngest being 10, and none of the others exceeded 36, except the patient above mentioned who died. There is no reason why splenectomy should not be performed on older patients, though there are obvious advantages in doing it in youth; from the age of 10 upwards children stand the operation well, and adhesions are unlikely to be present. Moreover, the dangers of destructive anaemias are obviated and the complications of the biliary tract are less prevalent. That the latter are real dangers is shown by the fact that seventeen patients in the series had the biliary tract involved, and in two of these biliary infection was the cause of death.

In cases in which both gall-bladder and spleen require operation it is not always wise to deal with them together. When the patient is weakened by a severe anaemia it might be safer to remove the spleen by as rapid an operation as possible and enable the blood to recover; and here may an observer of many such operations say a word in favour of the transverse incision as promoting economy of time and ease in handling.

Preliminary transfusion of blood should not be entertained lightly, certainly not without a pilot dose, for it may be recalled that in two cases of this series (Ford and Bass), although the bloods were most carefully typed, severe jaundice promptly ensued, and aggravated the already serious condition of the patients. In the light of experience the patient Bass would have had a better chance from splenectomy on admission to hospital, despite her grave condition. It is interesting to reflect whether a blood transfusion of this patient *after* splenectomy would have produced the same severe jaundice.

An enlarged spleen in a young patient, even to all appearances well, should prompt watching and repeated observations of the blood. Sometimes a slight jaundice comes and goes; again in some cases it is even absent altogether. Think of B. Tope, aged 10, apart from her family history. She is a bright, merry child of healthy appearance; she has an enlarged spleen; she has never shown any jaundice; her blood picture shows only a slight poverty of red cells. Yet a fragility of 0.6 to 0.4, 13 per cent. reticulocytes, and a positive indirect van den Bergh reaction give the key to the diagnosis, though a superficial examination of the blood would not. There can be no doubt that her spleen should be removed. The justification for not doing splenectomy lies in mildness of the anaemia with low count of reticulocytes and low van den Bergh indirect reaction, all after several investigations under varying conditions. Absence or slightness of jaundice is no justification for *laissez-faire*.

The following case illustrates incompleteness of cure after splenectomy, perhaps caused by undue delay in the performance of the operation. (Reported previously by Campbell.[35])

P. Phil, at the age of 14, was a pale, ill-looking child, with a lemon-tinted skin and an enlarged spleen. Her blood picture was as follows: red blood cells, 1,396,850; haemoglobin, 15 per cent.; colour index, 0.6; white blood cells, 6,000. More than once she had a haemolytic crisis. Nowadays with these findings her spleen would be removed, but in fact it remained till the patient was 29, after she had married, and had given birth to two children. That it was fortunate the delay in splenectomy did not bring her disaster is shown by her family history. One brother "died of spleen" at 1 year old; at the necropsy a very big spleen was found. One brother, alive, aged 5, spleen palpable, was treated, when aged 9 months, at the Evelina Hospital, for "profound anaemia." Mother healthy. A maternal uncle and a maternal aunt have each had their spleens removed. One of the patient's children is yellow. This patient did not completely recover a normal blood count after splenectomy. Thus, on November 19th, 1923, a few months before the operation, red blood cells were 3,750,000, haemoglobin 80 per cent. Splenectomy was performed in 1924, yet, two years after, the blood picture only showed 3,900,000 red blood cells, with haemoglobin 41 per cent., and in 1927, red blood cells 4,400,000, with haemoglobin 54 per cent.

This incompleteness of recovery of the red cell count does sometimes occur (as also in case E. H.), and may be due either to the bone marrow function failing to regain its full powers or to the fact that removal of the spleen is insufficient, and that haemolysis is excessive in other parts of the body, though in P. Phil the fragility was only moderately increased (0.5).

Before leaving this consideration of splenectomy it will be apposite and interesting to set forth the case of "Fordal," on whom the operation was performed as far back as 1887. Spencer Wells did the first splenectomy in England in 1865. His second and third splenectomies he did in 1868 and 1875. All of these were unsuccessful. His fourth splenectomy was performed on this patient when she was 27.

From the age of 9 the patient was troubled with frequent attacks of jaundice. When she was 14 she was growing "so large in front" that her mother was disturbed. At the age of 25 a large abdominal tumour was discovered below the umbilicus and near the centre of the abdomen, and was thought to be a fibroid. After two years' observation the tumour was noted to be larger, and the attacks of jaundice

* Delivered before the Northern Counties and Newcastle-upon-Tyne Medical Society on February 19th and 26th.

more severe, and accompanied by abdominal pain. It was decided, therefore, to remove the tumour. This was in the year 1887, three years before Minkowski first described acholuric jaundice. On opening the abdomen, two to three pints of ascitic fluid escaped, and the tumour was found to be a spleen, which was freely movable. Spencer Wells removed the spleen, which weighed 11 lb. 14 oz. The patient recovered, and her jaundice disappeared for good.

Two reflections suggest themselves: (1) the courage of the operator with the limited resources of his day and with the experience of all his three previous patients having died; (2) how imperfections in asepsis are in some measure counterbalanced by operative skill.

Over forty years have passed, and this patient is for her age enjoying good health. The fragility of her blood was examined a few years ago and was found to be still increased. Her only son developed haemolytic icterus in early childhood, and obstructive jaundice at about the age of 14. Two operations were performed by James Sherren, the first on the gall-bladder, which was full of pigment calculi and mud, and the second for removal of the spleen. The fragility was raised before the operation, and has remained so since—namely, 0.5—the last estimation having been made in 1927. Recovery was complete. This patient served throughout the great war.

The study of this disease illustrates the work of two master minds of the last century—Virchow in 1847, who concluded that bile pigment was formed outside the liver, and Spencer Wells, who in 1887 was the first to effect a cure of the disease by splenectomy.

PATHOLOGY

It is convenient to begin with the reports of the post-mortem examinations of Bass and Labourne. For these I am indebted to Professor Turnbull.

Necropsy Report on Patient Bass

Spleen, enlarged and firm, weighing 16¾ oz., with a swollen, moist, dark red pulp; minute distinct trabeculae and Malpighian bodies; few shallow, ill-defined subcapsular areas of induration and brown pigmentation.

Liver, enlarged (4 lb. 10 oz.), dark brown, with distinct lobular pattern, pale brown centres, and dark brown peripheries; gall-bladder and common bile duct normal.

Kidneys, enlarged (14½ oz.), with oedema, parenchymatous degeneration, and mottled greenish-brown jaundice.

Marrow, very rich and cellular, mottled with dark red in femur, ribs, sternum, and tibia (except for patches of fat in lower third). Jaundice of lymphatic glands, of ascitic fluid, of leptomeninges, of dura, and of ventricular fluid, but not of brain substance.

Necropsy Report on Patient Labourne

Spleen, greatly enlarged (2½ lb.), with fibrous peritoneal adhesions; cut surface showed a rich dark red pulp, with large irregular paler red areas; trabeculae and Malpighian bodies distinct; not enlarged; infarct anterior surface.

Liver, enlarged (5½ lb.), cut surface oedematous, and showing a slight rusty tinge. Liver gives marked free-iron reaction.

Gall-bladder contained about fifty faceted friable pigment calculi. Common bile duct showed no dilatation or stricture, and contained twelve small pigment calculi.

Kidneys gave marked reaction for free iron with Prussian blue test (Fig. 1 on Plate).

Marrow. Right femur, right tibia and humerus, and lumbar spine and sternum were occupied throughout with rich red marrow. Beneath the parietal pleura in the costo-vertebral angles and on the left side of the sixth to tenth thoracic vertebrae were four nodules of ectopic marrow (Fig. 2 on Plate). They were in close contact with bone, and showed a ragged surface where dissected from it. The cut surface of a nodule was red and homogeneous (Fig. 3 on Plate).

Microscopical Findings

I will now pass to the microscopical appearances in Labourne's case; for the demonstration and account of these I am indebted to Dr. W. D. Newcomb.

Spleen.—There is an irregular thickening of the capsule and slight fibrosis of the trabeculae. The Malpighian bodies are small, usually consisting only of a collection of lymphocytes around the eccentric artery. Many show hyaline degeneration, which is also present in the walls of many arteries and veins. The most noticeable change is in the pulp, which is engorged with red blood corpuscles. In the normal spleen pulp red blood cells and nucleated cells are about equal in numbers, whereas here red cells are in considerable excess. The venous sinuses are small and collapsed, containing a little albuminous fluid and a few red cells. Their lining endothelium is greatly swollen. There is no fibrosis or proliferation of reticulum cells in the pulp. A very few phagocytes containing red blood cells are present near some of the Malpighian bodies. Much iron-free pigment (haemofuscin) and a little iron-containing (haemosiderin) is present. In four out of seven blocks of spleen examined, fibrous nodules containing haematoxyphile strands are present. They are nearly all near blood vessels, and some involve the elastic tissue of the arterial wall. The dark staining filaments contain iron salts, as is shown by the Prussian blue test (Fig. 5 on Plate). They are the so-called Gandy-Gamna[40 41] nodules described by Gibson,[42] and have been found in many cases of acholuric jaundice as well as in other conditions.[43]

Liver.—The liver closely resembles that seen in pernicious anaemia. Much brown pigment, mostly haemosiderin, is present in the liver cells. Fatty degeneration of the cells at the centres of the lobules is also present. Fig. 6 on Plate (potassium ferrocyanide and basic fuchsine) shows the liver cells to be peppered with haemosiderin, and especially in the region towards the portal canal. Kupffer cells are also seen to contain red cells and iron-containing pigment.

Kidney shows well-marked haemosiderosis. The pigment is present mainly in the convoluted tubules and ascending limb of Henle's tubules.

Lymph glands are oedematous and their small vessels engorged. The germ centres are small and the lymph sinuses large. Most of the field is taken up by a lymph sinus containing numerous lymphocytes. The endothelium lining the sinuses is swollen, and many cells are free in the sinus. The reticulum cells are also active, and help in the formation of numerous macrophages, which fill both cortex and medulla of the glands. Some of these macrophages contain red blood corpuscles, and a few contain brown pigment, a little of which is haemosiderin.

Heart shows fatty degeneration, with a "tabby-cat" distribution and slight brown atrophy.

THE MARROW

Let us pass now to the minute anatomy of the marrow, in the first instance that of the femur and ectopic nodules belonging to Labourne, whose case represents the terminal stage of the disease, and with these the marrow of the child P. Tope, whose spleen was removed, that of W. G. which represents a milder form, and that of Bass the severe form, of the disease. These marrows have certain features in common. To the naked eye they are rich dark red marrows, with an absence of fat; under the microscope they are haemoblastic more than leucoblastic, and normoblasts are more numerous than megaloblasts; in a well-balanced case like W. G. they are twice as numerous.

Similarly, mitotic figures show a varying prominence in these marrows. In W. G. marrow they were prevalent, while in Bass and the child P. Tope scarce (see figure on opposite page). They were a prominent feature in the ectopic marrow of Labourne. This ectopic marrow (Fig. 7 on Plate) represents in striking fashion a hyperplasia—an endeavour of the blood-forming organ to meet the increasing drain of haemolysis. It is notably erythroblastic and active; mitotic figures are numerous in both myeloblasts and erythroblasts; many endothelial cells and some megakaryocytes are present. Free iron was found in the capsule of the nodule.

Formation of extramedullary marrow has been reported in the literature.[44] Thus Dorsey Brannon[45] reports the case of an infant with splenomegaly and anaemia in which

the hila of the kidneys were filled with red nodules containing the elements of hyperplastic marrow. Rich[46] has mentioned the occurrence of kidney-sized masses of bone marrow tissue in the thorax of a man who died from haemolytic jaundice.

Reverting to the case of Labourne, side by side with this evidence of a struggle to form new blood we have the evidence of a severe and fatal blood destruction. In the spleen there is evidence of active haemoglobin disintegration, but the amount of iron is not excessive. The haemoglobin is broken up there into bilirubin and iron-containing pigment, but these products pass away in the blood stream, the former in solution and the latter probably within endothelial cells. The pigment is found in large quantities in the liver and kidneys. Recall the section of liver which showed the polygonal cells to be packed with these pigment granules (Fig. 6 on Plate). The kidneys also showed well-marked haemosiderin, much pigment being present in the convoluted and Henle's tubules. The section of the bone marrow of Labourne (Fig. 8 on Plate) shows a more advanced stage, approximately to the marrow found in pernicious anaemia

It follows, therefore, that the naked-eye and microscopical manifestations of active marrow are evidences of endeavour but not of successful performance. A small amount of hyperplastic marrow will give the appearances that are to be seen in the femur, vertebrae, and other bones of Labourne, but these appearances are no measure of the marrow's output.

In acholuric jaundice the increased destruction of red cells is met, and for a time successfully, by increased red cell formation, as evidenced by the presence of reticulocytes and microcytes, with often a low red blood count and with even apparent health and an active normoblastic marrow. As time goes on the haemolysis holds greater sway. The capacity for blood formation declines and the blood picture approximates more to that of pernicious anaemia, in which impaired blood formation is a feature, side by side with blood destruction.[47 48] There remains, however, the essential difference that the marrow in pernicious anaemia is megaloblastic during the relapses and normoblastic during the remissions, whereas in haemolytic icterus it remains normoblastic throughout, though the number of megaloblasts is increased.

Put in another way, the dominant lesion in acholuric jaundice is haemolysis, which in the early stages is met by the overaction of healthy marrow. When the stage of exhaustion appears the marrow becomes more normoblastic, and eventually shows a tendency towards the megaloblastic; whereas in pernicious anaemia the marrow is in an exhausted state from the onset of the disease. In both alike the presence of an active hyperplastic marrow is not evidence that blood formation is winning; it represents striving, but is not a measure of successful achievement; there is a cellular hyperplasia without functional efficiency.

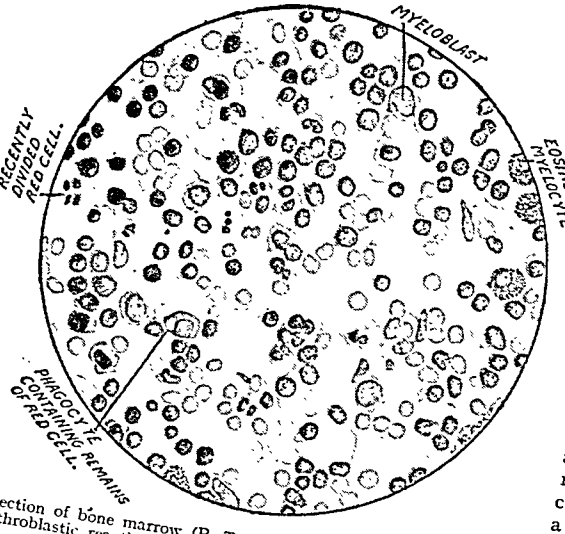
As a contrast to the foregoing it is worth making brief reference to sprue anaemia. Here failure of blood formation is the main feature; here there is no increased van den Bergh reaction, no reticulocytosis, and the marrow is aplastic.[49] It is possible that the generalized atrophy of the intestinal mucous membrane in sprue prevents the absorption of the necessary anti-anaemic factor, and a blood picture resembling pernicious anaemia results.

ACQUIRED HAEMOLYTIC ICTERUS

The more closely haemolytic icterus is studied the more does doubt grow as to whether in the strict sense an acquired form exists. Manifestations early in life can be so slight as to pass unnoticed or be forgotten. Take the case of Labourne. It was only at the end of her life that her attacks of anaemia were found to be associated with increased fragility. It was only after repeated questionings that the jaundice of her early life came back to her memory, and but for that fact she might justly have been thought to have acquired the disease in adult life.

The slightness or absence of one or more of the manifestations makes it easy for the condition to pass unnoticed. It is only when observation becomes stimulated, and then extended to the patient, or the patient's family, or both, that discovery ensues. For instance, a moderately enlarged spleen may be found in a patient of active life. Investigation may disclose a red cell count of, say, 4½ millions, a fragility within the normal, a positive direct van den Bergh with no jaundice. If there is no disturbance of the patient's health, and no discovery of any members of the family affected with more typical forms of the condition, the cause of that splenomegaly remains a mystery. All the while, the marrow has been overtaxed, involved in over-production of red cells to maintain equilibrium. But suppose the marrow fatigues as the result of untoward conditions like hardship or illness (for example, a septic process), or the haemolytic process itself becomes accentuated and jaundice appears, there is the further possibility that the fragility may increase, and this, with an inherited overactive reticulo-endothelial system, may turn the scale, causing the symptoms of haemolytic icterus to appear. It is known that fragility can vary and change in the same patient and in different conditions—for instance, in pernicious anaemia it diminishes, while in blackwater fever, as Creed has shown,[50] it may increase. In the sense that latent defects may be accentuated so as to become clinically manifest, haemolytic icterus can be acquired, but the defects themselves are inborn.

Paschkis,[51] discussing the question, describes the case of a patient who, while being treated for abdominal pain and diarrhoea, was found to have a palpable spleen and an icteric tinge. Investigation showed that there were raised fragility (namely, 0.58 to 0.3), indirect van den Bergh 3 units, and marked urobilinuria. This might have been regarded as an acquired case. It was not, but was a congenital haemolytic icterus then for the first



Section of bone marrow (P. Tope) taken by biopsy; showing erythroblastic reaction with few mitotic figures.

time made manifest. A brother, in excellent health, was found to have an enlarged spleen, a raised fragility, 0.52 to 0.3, and moderate urobilinuria.

I would like to thank Dr. Robert Hutchison, Dr. Otto Leyton, Dr. Theodore Thompson, Dr. Adolphe Abrahams, Dr. Campbell, and Dr. C. S. Atkin for letting me use their cases. One of Dr. Leyton's cases was particularly valuable. I am indebted, also, to Dr. Creed of King's College Hospital for his valuable method of estimating fragility of the blood. I have referred in the text to the reports of Professor Turnbull and Dr. W. D. Newcomb. I gratefully acknowledge the help and criticism of Dr. Mathilde Hunter and Dr. Donald Hunter in the gathering of numerous observations set forth in the text. I have also received valuable aid from Dr. Daniel Davies, and I think it will be admitted that the illustrations by Messrs. Shiells and Ford and Mr. S. A. Sewell are excellent.

A Lecture
ON
SOME SURGICAL ASPECTS OF FAULTY NUTRITION*

BY
ROBERT McCARRISON, C.I.E., M.D., D.Sc., LL.D., F.R.C.P.
COLONEL, INDIAN MEDICAL SERVICE; HONORARY PHYSICIAN TO THE KING; DIRECTOR, NUTRITIONAL RESEARCH, INDIAN RESEARCH FUND ASSOCIATION

The laboratories of the Indian Research Fund Association, devoted to the study of diseases associated with faulty nutrition, are located at Coonoor in the Blue Mountains (Nilgiris) of Southern India, 6,000 feet above sea-level. Their location is fortunate, for the temperature is equable, never very hot or very cold: the mean winter temperature rarely falls below 50° F., the mean summer temperature rarely reaches 80°. A good deal of rain falls in these hills, Coonoor coming within the range of both the south-western and the north-eastern monsoon: the former brings with it only occasional heavy showers, while the latter may involve us in heavy rainfall during November, December, and January. But it is rare that a day passes without some hours of bright sunshine and clear skies. Conditions are such that no elaborate buildings are required for the animals. Indeed, I have been content with corrugated-iron sheds, roofed with the red tiles of the country, and having floors tiled, sloped, and adequately drained. I am fortunate also in having a large staff of animal attendants, who are now highly skilled in their work. In these favourable circumstances it is possible to ensure ideal conditions of hygiene and exposure of the animals to sunshine practically every day the whole year round. A simple but adequate means of sterilizing the animal cages is adopted, and the hose-pipe and creosol solution are used freely on the tiled floors. The walls are whitewashed frequently. The test of cleanliness is a simple but severe one. In an animal room of some 30 by 15 feet there may be as many as 500 rats. Should the visitor be made aware of their presence by his sense of smell then there is something wrong with the sanitation. I may add that he rarely is.

* The first of two lectures on experimental research at the Pasteur Institute, Coonoor, S. India, delivered before the Royal College of Surgeons of England.

FREEDOM OF WELL-FED ANIMALS FROM DISEASE

In these conditions there live some 1,000 stock albino rats—the source from which the large numbers of young animals required for my work are obtained. For this work I use on the average 1,100 animals a year. The pairs are kept in roomy, netted-wire cages, screened and straw-filled, in which they find the peace and comfort necessary for fruitful breeding. As a rule, five or six litters are taken from each pair, and the older animals are thinned out at the age of 2 years—a life span said to correspond approximately to the first 40 to 50 years of life in man. The average number in each litter is eight, but litters of twelve are frequent, and those of fifteen are not uncommon. The mothers invariably rear the whole of their young.

This stock is fed on a diet similar to that eaten by certain peoples of Northern India, among whom some of the finest physical specimens of mankind are to be found. The diet consists of whole-wheat flour, unleavened bread (*chapattis*) lightly smeared with fresh butter, sprouted Bengal *gram* (legume), fresh raw carrots and cabbage *ad libitum*, unboiled whole milk, a small ration of raw meat with bones once a week, and abundance of water, both for drinking and for washing purposes.

The point of these somewhat lengthy, but necessary, details is this: during the past two and a quarter years there has been no case of illness in this "universe" of albino rats, no deaths from natural causes in the adult stock, and, but for a few accidental deaths, no infantile mortality. During this period I have myself performed complete post-mortem examinations on 1,189

of these rats, ranging in age from the newborn to 2 years. In none have I encountered any macroscopical evidence of disease, with the exception of an occasional cyst in the liver, containing tapeworm larvae. How the animals became infected with tapeworm I do not know, unless it be from the straw bedding which they nibble. Both clinically and at post-mortem examination this stock has been shown to be remarkably free from disease. It may be that some of them have cryptic disease of one kind or another, but, if so, I have failed to find either clinical or macroscopical evidence of it. Disease and death have been excluded, almost completely, by minute attention to three environmental conditions: cleanliness, comfort, and food.

HIGH INCIDENCE OF DISEASE IN ILL-FED ANIMALS

I wish now to turn to my experimentation rooms. Here are the same corrugated-iron huts, the same cages, the same scrupulous cleanliness, if anything more scrupulous than in my stock animal houses; for here there are attendants, armed with forceps and crumb-tray, who pass from one cage to another removing faeces which may occasionally adhere to the half-inch meshes of the screens on which the animals live. There is no coprophagy; it is not allowed. Nor do we meet with the phenomenon of "refection." Here the animals are exposed in the same way to the sun's rays. But they live in separate cages, as do the controls for each experiment—isolated from their fellows; they are thus less contented than their more fortunate kith and kin in the stock animal rooms, and they are more exposed to the effects of chill, since they cannot be given straw bedding, though each evening they are given bedding of clean cotton-waste. The main regard in which they differ from the stock animals is in their food, which is always faulty in some way or another. Further, as my business is to learn, as far as I can, how the foods eaten by the people of India are related to disease, synthetic diets are used comparatively rarely, and then only for special purposes. The materials entering into the various faulty dietaries are usually those in use by the people of India; sometimes actual Indian dietaries are used.

During the last two and a quarter years I have examined 2,243 of these improperly fed rats at post-mortem examination—that is to say, during the same period in which I failed to find disease in the universe of stock rats. The following are the morbid states I have encountered:

Lung diseases: pneumonia, broncho-pneumonia, bronchiectasis, pyothorax, pleurisy, haemothorax.
Diseases of the nose and accessory sinuses: sinusitis.
Diseases of the ear: otitis media or pus in the middle ear.
Diseases of the upper respiratory passages: adenoid growths.
Diseases of the eye: conjunctivitis, corneal ulceration, keratomalacia, panophthalmitis.
Gastro-intestinal diseases: dilated stomach, gastric ulcer, epithelial new growths in the stomach, cancer of the stomach (in two cases only), duodenitis, enteritis, gastro-intestinal dystrophy, stasis.
Diseases of the urinary tract: pyonephrosis, hydronephrosis, pyelitis, renal calculus, ureteral calculus, dilated ureters, vesical calculus, cystitis, incrusted cystitis.
Diseases of the reproductive system: inflammation of the uterus, ovaritis, death of the foetus *in utero*, premature birth, uterine haemorrhage, "hydrops testis."
Diseases of the skin: loss of hair, dermatitis, abscesses, gangrene of the tail, gangrene of the feet, subcutaneous oedema.
Diseases of the blood: anaemia, a "pernicious" type of anaemia, *Bartonella muris* anaemia.
Diseases of lymph and other glands: cysts in the submaxillary glands and accessory glands in the base of the tongue, abscesses in the same, and occasionally also in the inguinal glands, enlarged mesenteric, bronchial, and other lymph glands.
Diseases of the endocrine system: lymphadenoid goitre, enlarged adrenal glands, atrophy of the thymus, and, very occasionally, haemorrhage into the pancreas.
Diseases of the nervous system: polyneuritis.
Diseases of the heart: cardiac atrophy, occasionally cardiac hypertrophy, myocarditis, pericarditis, and hydropericardium.
Oedema.

Not infrequently animals are found to be suffering from more than one of these diseases.

I say nothing of diseases of the bones and teeth, since the diets were not specially designed for their production, and the practice of exposing the animals to sunlight—a practice followed because the average Indian is daily so exposed—probably compensated for any lack of vitamin D in the diets. But mention might be made of crooked spines and distorted vertebrae, and of imperfect teeth, which are encountered not infrequently. The list I have given includes only those morbid states which I have myself seen (there may have been, and no doubt were, others which I failed to see); it is a list prepared from the post-mortem records of the 2,243 imperfectly fed animals.

Here, then, is an experiment on a large scale extending over a period of two and a quarter years. On the one side there is, as controls, a community of hygienically housed rats, fed on a well-balanced diet composed of natural foodstuffs—whole-wheat, pulses, raw milk, butter, fresh vegetables, and fresh meat with fat and bones occasionally, so combined as to provide in proper amount and proportion all elements and complexes necessary for normal nutrition. On the other, there is a community of rats, also hygienically housed, but fed on ill-balanced diets composed mainly of cereal grains or cereal products and vegetable fats with little or no milk, butter, and fresh vegetables. The contrast between these two communities is remarkable; and I claim for this experiment that it proves conclusively that one-sided diets which are disproportionately rich in cereals and poor in animal fats, milk, and *fresh* vegetables are capable of inducing in albino rats a large proportion of the diseases included in our calendar of human ailments. I may add that of all the faulty diets I have used that composed of white bread, margarine, tea, sugar, jam, preserved meat, and scanty overcooked vegetables—a diet in common use by many people in this country—proved to be one of the worst, and most likely to be associated in rats with many of the morbid states I have mentioned, especially diseases of the lungs and of the gastro-intestinal tract.

Rats are not the only animals I use; guinea-pigs, rabbits, pigeons, and monkeys are also employed. In them I have found many of the above-mentioned diseases, and some others besides. Of the latter I may mention the following: prescorbutic states, scurvy, and duodenal ulcer in guinea-pigs, hyperplastic goitre in rabbits, epithelioma contagiosum, polyneuritis, and true beri-beri in pigeons, and ulcerative colitis in monkeys. Two conditions I have not, so far, encountered: gall-stones, observed by Fujimaki (1926), de Langen (1929), and others; and cataract, observed by Eckstein and Szily (1924).

In every species—pigeons, rats, guinea-pigs, rabbits, and monkeys—I have found the same thing: properly fed animals remain remarkably free from disease, improperly fed animals are remarkably subject to it. It is reasonable, therefore, to assume that the human species is no exception to this rule, and that many of the ailments to which man is erroneously supposed to be heir are the outcome of his improper feeding. Some may hold that it is not possible directly to translate to human experience the results of an experiment such as that just described. This may be true, if we seek to do so too rigidly and fail to take sufficient count of other environmental factors to which human beings may be exposed. But, in general, the results of an experiment of this kind do, in my opinion, apply to man, and point the way to a solution of many etiological problems connected with his physical infirmities.

DEFICIENCY IN VITAMIN A

In the above list of diseases there are many of interest to the surgeon. Sinusitis, adenoid growths, otitis media, gastro-duodenal ulcer, gynaecological ailments, certain types of goitre, and urinary calculus are some of them. At first sight it would appear that morbid states so dissimilar as adenoids and stone in the bladder had nothing in common, yet etiologically they are not so far apart. All these surgical conditions were found to have this in common: they occurred in animals whose ill-balanced diets contained little or no vitamin A bearing food materials, such as raw milk, butter, cod-liver oil, carrots, and fresh green vegetables. In my hands these food materials, when suitably combined, have protected my animals from these diseases, and I do not doubt that in the hands of the surgeon they will go far to protect his human patients from them and facilitate their cure and non-recurrence after operation. I lay stress on the food materials themselves rather than on any particular ingredient of them, or any particular quality possessed by them, believing, as I do, that in Nature's laboratory all elements and complexes needed for normal nutrition are combined in a way which we cannot wholly achieve, and that the health-giving properties of food are largely dependent on this combination. For my own part I have been able to devise no synthetic diet which can equal in these properties a mixture of natural food materials such as that on which I feed my stock rats and on which some of the finest physical specimens of mankind are reared. Nevertheless, a principal fault of the diets I have used, and one which is in considerable part responsible for the surgical diseases I have mentioned, is insufficiency of the substance or quality which we speak of nowadays as vitamin A. The effects on the organs and tissues of the body of the insufficient use of vitamin A bearing foods have thus a particular interest for the surgeon.

[Here followed a lantern slide demonstration in which the lecturer showed the typical keratinization of epithelia, the concourse of lymph cells, the secondary inflammatory changes, the ulceration of, and epithelial new growths in, the stomach, and the lymphadenoid goitre occurring in rats fed on diets containing an insufficiency of vitamin A bearing ingredients.]

The sites in which these changes have so far been found in experimental animals are the nares, larynx, trachea, bronchi, submaxillary glands, parotid gland, and the accessory salivary glands of the tongue and pharynx; the pancreatic duct, bladder, ureter, and pelvis of the kidney; the uterus and oviduct; the epididymis, prostate, and seminal vesicles; the conjunctiva, Meibomian gland ducts, cornea, lacrymal gland, Harderian gland, and the extra-orbital (lacrymal) gland; the thymus (Wolbeck and Howe, 1925). To this list I must myself add the thyroid gland. "The distinctive or peculiar gross changes are those due to mechanical factors sequential to the formation and retention of desquamated, keratinized epithelial cells" (Wolbeck and Howe, 1925). Thus cysts, bronchiectasis, hydronephrosis, dilatation of the bladder and ureters may be produced by blockage of ducts or other passages.

These changes occur more readily, and within a shorter time, in young than in older animals—a thing to be expected in the growing animal. They are focal in distribution, and may be confined to narrow or to wide areas, to a few tissues or to many. They vary in their location in different species of animals and in different individuals of the same species. I have, for instance, found the adenoid-like growths in the upper respiratory tract in rats to all appearances normal except for subnormal growth. They are best seen and more widespread in animals fed on synthetic diets devoid of vitamin A; but since man's food is rarely or never wholly lacking in this factor it is of importance to realize that they occur also in animals fed on human dietaries which are by no means devoid of it, though containing it in insufficient quantity. It seems probable that these changes are helped in their occurrence by the existence of other food faults in the diet, such, for instance, as deficiency of suitable protein and mineral elements, and by the condition of semi-starvation into which the animals fall. It seems probable also that other environmental conditions, such as climate, altitude, humidity, may favour or hinder their occurrence. Thus it is universally agreed that the changes in the eye and its neighbourhood are, in rats, the most frequent; but they are not so in the climate of Coonoor; indeed, the eye is often not affected when other tissues are. I mention these matters to illustrate the interplay between nutrition and other environmental conditions (climatic and bacterial) in giving rise to the final morbid state. The worn tyre may travel far along the smooth-surfaced road before encountering a flint; its course along the flinty byway is less secure. So it is with the epithelial treads of the body surfaces when deteriorated by faulty nutrition.

The varying occurrence and location of the changes due to vitamin A deficiency are among the most interesting things about them. Thus in monkeys fed on a diet said to be complete in other regards, but lacking a sufficiency of vitamin A, eye changes, sinusitis, and mastoiditis, so common in rats, are, as Tilden and Miller (1930) have lately shown, conspicuous by their rarity. Twelve years ago (1919) I demonstrated that the colon was of all organs in monkeys the most sensitive to faulty nutrition; and the recent work of Tilden and Miller, while confirming this observation, re-emphasizes the importance of vitamin A deficiency in causing the ulcerative colitis which is so conspicuous a feature in these animals. The monkey's colon is also very sensitive to deficiency of other vitamins (McCarrison, 1919), particularly of vitamin C, "which causes a condition varying from local congestion and thickening of the mucous membrane to one indistinguishable from ulcerating and sloughing dysentery" (Mackie and Chitre, 1928).

In some of these respects man resembles the rat more than the monkey. Thus he is very susceptible to the eye changes resulting from insufficiency of vitamin A bearing foodstuffs in his diet, if one may judge by the prevalence of keratomalacia in the Madras Presidency, and by its amenability to treatment by cod-liver oil (Wright). But I suspect that he resembles the monkey in the sensitiveness of his colon to food deficiency; the number of cases of ulcerative colitis of "unknown" cause (Menon, 1930) occurring in India is sufficient to justify this suspicion. But however the changes vary, either as to extent or location, they are always to be found in animals of all species so far examined—rats, guinea-pigs, pigeons, fowls, and monkeys—and in man himself. Reference has already been made to their occurrence in the eye, and its neighbouring tissues, in Madrassis, and to its proven association with the specific deficiency. But there are few post-mortem studies of pure vitamin A deficiency in man. Fortunately there is one: I take it from a paper by Wolbeck and Howe (1925):

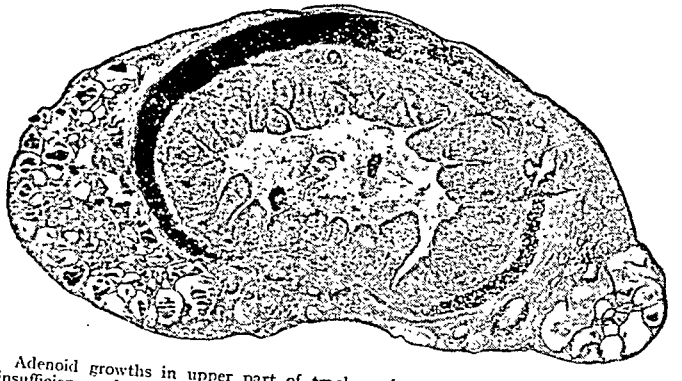
> "*Vitamin A Deficiency in the Human.*—There has been but one pathological description of a fatal human case (Wilson and du Bois). This post-mortem, done in the pathological service of one of us at the Children's Hospital, is adequately recorded. We have recently re-studied the tissues and can add nothing of importance. Keratinization of the epithelium of the renal pelvis and large size of Hassall's corpuscles in the thymus were overlooked. The keratinization of the pancreatic ducts is more striking than any seen by us in the pancreas of rats. In respect to the keratinizing changes in the lungs, uterus, submaxillary gland ducts, and thymus, the picture was identical with that in our experimental rats.

The order of changes in the human case was somewhat different, in that the salivary glands showed only slight changes. The peculiar swollen epithelial cells with nuclear inclusion bodies in the ducts of the parotid and submaxillary glands are unlike any changes seen in rats. The lacrymal gland showed only slight changes and no keratinization. The eyes were not removed for study.

"The importance of this human case is that it did show the epithelial changes which we have produced in rats, and, therefore, contributes irrefutable evidence for an important part of our thesis to the effect that vitamin A deficiency affects epithelial tissues in a specific manner."

The testimony of these experienced observers is of the highest value, and leaves no room for doubt that the tissue changes occurring in the lower animals, consequent on the *insufficient* supply of vitamin A bearing foodstuffs in the diet, occur also in man. I again emphasize the word "insufficient," since, in my own experience, and in that of Tilden and Miller (1930), in monkeys the diets associated with them are not necessarily devoid of vitamin A, though always they are poor in this factor.

These changes are independent of infection, though infection is often superimposed upon them. Indeed, it is because of them that infection becomes possible, since they occur for the most part in "outside" coverings of the body; the respiratory passages, the urinary tract, the reproductive tract, the conjunctiva, the nasal passages, the ear, and the ducts of organs. They are breaches in the walls of the body's defences, through which the invading microbe may enter. In this sense vitamin A is "anti-infective"; but the "anti-infective" quality is shared with other vitamins—C, B, and D—though exhibited by them in other ways.



Adenoid growths in upper part of trachea of rat fed on a diet containing an insufficiency of vitamin A bearing ingredients.

Two points of interest to the surgeon remain to be mentioned: (1) If rats, fed on a diet deficient in vitamin A, be artificially infected with a bacterium, such as the Breslau bacillus (paratyphoid), they usually die from the resultant infection. But some may live, and in them the infection persists in the lymph glands "for a very long time after the general infection has been overcome" (Lassen, 1930). It seems to me probable that chronic enlargement of lymph glands in childhood, due usually to infection of one kind or another, may often be due to such persistence of infection as a result of a vitamin A deficient diet. Further, it seems probable that the focal breakdown of the tissue defences induced by this deficiency may be concerned in the causation of those "septic foci" about which so much is heard nowadays. (2) I have spoken above of breaches in the walls of defence against bacterial invasion consequent on the use of vitamin A deficient diets, and I have mentioned that other vitamins may also exercise an anti-infective action, though exhibiting it in a different way. This way may not need the breaching of the walls, but their scaling. I take the following from an unpublished manuscript which Dr. Lloyd Arnold of the Department of Pathology and Bacteriology, Chicago, has recently sent me:

"McCarrison has repeatedly called attention to the early appearance of digestive disturbances in vitamin deficiency studies. The pathological examination of the dead animals following avitaminosis experiments shows evidence of tissue changes due to infections of various kinds. We have found that one of the first demonstrable changes in avitaminosis is an alteration in the distribution of the bacterial life within the lumen of the intestinal tract. The bacteria ingested by the mouth are not destroyed in the usual manner, but remain viable for many hours within the contents of the whole length of the small intestine. The mixed bacterial flora of the large intestine ascend into the upper levels of the small intestine. There is a gradual and progressive loss of the power of the body surface to control the microbic life existing in contact with it. These findings have been constant, and hold for vitamin A, B, and D deficiencies. By the time the adult animals show a loss in body weight, or the young animals show a stationary weight-curve, there is evidence of bacterial invasion of the mucosa of certain surfaces. These latter observations have been made by numerous investigators. We attribute the early inflammatory changes in the lining membranes of the eye, mouth, throat, alimentary tract, etc., to the loss of power of these body surface coverings to regulate the bacterial flora in contact with their cells. This precedes evidence of invasion of the membranes by bacteria."

This statement, so amply demonstrated by Dr. Lloyd Arnold's investigations, calls to mind the contentions of Sir Arbuthnot Lane and Dr. Nathan Mutch in regard to infection of the upper reaches of the intestine consequent on chronic gastro-intestinal stasis: a condition which, as my own researches (1921) have shown, may be due to the consumption of faulty food from the "first bottle" onwards through life.

The function of vitamin A, so far as it is known at present, is thus to maintain the functional integrity of the cells covering body surfaces, thereby preventing invasion of the organism by microbic agents.

Here, however, I must re-emphasize the position, which I reached more than ten years ago and which all my subsequent work has but strengthened, that, whatever the specific function of any vitamin may be, vitamins are but links in the chain of essential substances requisite for the maintenance and harmonious regulation of the chemical processes in the tissues, and their action must be considered in connexion with metabolism as a whole—that is, in relation to balance of food ingredients in general, to organs of digestion and assimilation, and to endocrine regulation of metabolism. Their deficiency, like that of the other elements and complexes necessary for normal nutrition, leads to depreciation of cellular function; depreciation of cellular function is the foundation upon which disease is built (McCarrison, 1921).

Surgical Diseases which may be Associated with Faulty Nutrition

I find I have left myself little time to discuss specific diseases of surgical interest which may be associated with faulty nutrition. Mention may, however, be made of a few, illustrative of the several departments of surgery, but excluding the ophthalmic surgeon, to whose department some reference has already been made.

Adenoids

In the lantern slide demonstration I showed examples of adenoid growths in the trachea. (See *Fig.*) In rats these growths were the result of faulty feeding. It is no far cry from the trachea to the nasopharynx, where changes similar to those in the trachea of rats are so

commonly found in children. And perhaps I might have found adenoids there also had my serial sections extended up to that situation. In work such as this it is constantly happening that one cannot do everything one wants to do, or that in looking for one thing one overlooks another. So whether or not rats do get "adenoids" as the surgeon understands the term, I do not know, but they certainly get "adenoid-like growths" in a region not far removed from the nasopharynx; and they get them because of faulty nutrition. And if in the trachea of rats, why not in the nasopharynx of children? The more so since Williamson and Pearse, and more recently Wollard (1931), have shown that the pharyngeal entoderm is an anatomical entity which embraces the lymphatic tissue of the nasopharynx and trachea. Evidence provided by the racial distribution of adenoids is not lacking to show that their occurrence may be related to faulty food. Thus Van der Bogert (1927) reports that Labrador Eskimos and those of Baffin Island who have been in contact with Western civilization, and whose food has changed accordingly, develop adenoids, whilst Polar Eskimos, whose diet has remained unchanged for centuries, do not. My own experience in rats would lead me to expect such a sequence of events.

Otitis Media

In rats one of the most common consequences of faulty food deficient in vitamin A is pus in the middle ear; its incidence may reach 60 or even 70 per cent. It is a condition of great frequency among school children in England and Wales, and, although its occurrence, as a sequel of certain diseases of childhood, is well known, the probable nutritional factor in its causation does not appear to me to have received the consideration it deserves. According to Hastings (1925) a high proportion of all cases occur before the fifth year, and many before the first birthday. In 1923 no fewer than 46,000 children had ear trouble; while 90 per cent. of deafness in adults is due to preventable causes in childhood. Ponfick reported that of 100 necropsies in children under 4, who died from various diseases, 91 showed evidence of middle-ear disease, and in only ten of these was the trouble recognized during life. The causes giving rise to middle-ear disease interact with one another: they are squalid poverty—with its accompaniment of malnutrition—neglected catarrh, tonsils and adenoids, mouth-breathing, and the after-effects of measles, scarlet fever, and diphtheria. My rats do not suffer from the three last; but my experience in these animals leads me to believe that the insufficient supply of vitamin A bearing foods may be responsible for middle-ear disease in children to an extent much greater than is generally believed.

Gastro-Duodenal Ulcer

Twelve years ago (1919) I recorded the occurrence of this condition in guinea-pigs fed on a scorbutic diet of crushed oats and autoclaved milk. Recently I have repeated this experiment with the same result; and in this later experience I have found duodenal ulceration at all stages of the process up to perforation (in one case), the resulting abscess being localized. Magee, Anderson, and McCallum (1929) have observed similar conditions in calves fed on food deficient in certain essentials. Gastric and duodenal ulcer are extremely common in Southern India, especially in South Travancore. The suggestion was made to me by Lieut.-Colonel E. W. C. Bradfield, I.M.S., late superintendent of the General Hospital, Madras, and by Dr. T. Somervell of the South Travancore Medical Mission, that the dietaries of the poorer classes, among whom these conditions were most common, might be concerned in their causation; an experiment was accordingly undertaken to put this view to the test.

Albino rats were used; and the experiment was continued for 675 days. Two diets were employed: one, resembling that eaten by the poorer class Madrassi, and containing rice, red pepper (chillies), tamarind, a little fish, and *conjee* (rice water); the other, resembling that of the poorer class Travancorian, and consisting largely of tapioca root, with rice, a little fish, red pepper, and rice water. Both these diets were very deficient, not only in vitamins of the A, B, and C classes, but in other regards also. The diets were prepared and cooked in the same way as by the people using them. It so happened that about the time this experiment matured I had occasion to examine at post-mortem some hundreds of well-fed stock rats who had lived through the same period of 675 days. In none of these was gastric or duodenal ulcer found. Among the rats fed on the Madrassi diet the incidence of gastric ulcer was 11.1 per cent., while the duodenum showed no signs of ulceration; among those fed on the Travancore diet, 27.7 per cent. had gastric ulcer, and in 11.1 per cent. of these the ulcers occurred both in the proximal (squamous) and in the distal (mucous) portion of the organ. No duodenal ulceration was found in animals fed on either diet, although in 11.1 per cent. of those fed on the Travancore diet a marked duodenitis was present. The limitation of the ulceration to the stomach in rats was the more remarkable because the Travancorian diet is especially associated in man with duodenal ulcer. A further point of difference between the two groups was that while in animals fed on the Madrassi diet the ulcers were limited to the squamous portion of the organ, in those fed on the Travancorian diet the ulcers occurred for the most part in the mucous portion.

Here, then, is unequivocal proof that two diets in use by certain people in India are capable of causing peptic ulcer in albino rats. The high incidence of this condition among the human users of these diets may therefore be definitely attributed to this cause. As to the mechanism of ulcer production—that is another matter; the one that concerns me, as an investigator in the service of the Indian people, is that two of the diets used by them do cause peptic ulcer, while a third, on which my stock rats are fed, does not. For them the moral is unmistakable.

The excellent results reported by Harris (1928) in the treatment of gastric and duodenal ulcer by vitamin-rich food are in conformity with the findings in this experiment.

Gynaecological Ailments

The health of the womb and its appendages is dependent in various specific ways on the quality of the food. It is one of the sites in which faulty nutrition implants its seal, as has been shown, not only in the lower animals, but in the human being. The ovary, also, and the oviducts, may be affected in a similar way; while changes brought about in the bony framework of the pelvis may, as is well known (Stoney, 1930), be a fruitful cause of stillbirth and maternal mortality in childbirth. Fertility, the course of pregnancy, labour, resistance to infection following labour, and lactation may all be affected adversely by defects in quality of the food. It is said that "nothing so predisposes to maternal death at confinement as an unhealthy womb" (Pearse and Williamson, 1931), and while imperfectly terminated pregnancies, aborted pregnancies, and other conditions may, and often are, the causes of this unhealth, faulty nutrition may also be concerned in it. Often I have seen deficiently fed rats that die in pregnancy or at term from causes dependent on their faulty nutrition, and often also rats that come to term only to die with five or six foetuses in their wombs. Some of the anaemias of pregnancy so common in India are dietetic in origin—as the recent work of Dr. Lucy Wills has so conclusively shown. I make no claim that in human beings faulty nutrition is invariably a factor in the production of the tragedy of maternal mortality in childbirth, however frequently it may be so in rats. But here, as in other departments of medicine, experience in rats has pointed

surely to means for the relief of suffering in mankind; and it might be well were we to accept this guidance more readily in regard to our women, and urge insistently that the mothers of our race be fed with knowledge and understanding.

Lymphadenoid Goitre and Graves's Disease

A lecture might, by itself, be devoted to this subject, so much is the health of the thyroid gland and its departures from health associated with perfect nutrition on the one hand, and with faulty nutrition on the other. Lymphadenoid goitre, originally described in man by Williamson and Pearse (1925), is "the hypertrophic reaction of a physiologically inefficient organ with which there occurs a preponderance of lymphocytic aggregates, fibrosis, and a peculiar atrophy of the parenchyma." I have produced it under experimental conditions in rats (McCarrison, 1927). In these animals the physiological inefficiency of the gland can be induced by faulty nutrition, but the exciting cause of the goitre is some positive factor which has so far escaped me. One cannot be sure when this type of goitre is going to occur; all that one can be certain of is that it surely will occur, in its own good time, provided the food is of a certain character. It is unrelated in its origin to iodine deficiency. I understand that it is now possible to diagnose this condition clinically in the human subject, and that thyroidectomy has been performed for its relief in not a few cases within recent years in London. Mention of its association with the use of foods deficient in vitamin A recalls the observation of Rabinowitch (1929) that a combination of relatively minute quantities of organic iodine, with a concentrated preparation of fat-soluble vitamins, causes as marked a lowering of the metabolic rate in Graves's disease as larger doses of iodine when not combined with these vitamins. Fraser and Cameron (1929) have made a similar observation, using small amounts of sodium iodide instead of organic iodine. More recently Abelin (1930) has demonstrated the great value of vitamin treatment in Graves's disease.

"The hyperthyroid condition," he writes in his recent book, "is one of the abnormal raising of the metabolic rate, together with a lowering of anabolic processes. This disorder of lowered activity of cells can be successfully combated through nutrition. Among other things, for this purpose, the co-operation of vitamins is necessary. The organ destruction in thyrotoxicosis is caused by a vitamin-poverty in the body. The need for vitamin supply is, therefore, increased in hyperthyroidism. Through plentiful use of vitamin-rich substances—cod-liver oil, egg-yolk, yeast, tomatoes, spinach, etc.—the great destruction of sugars has been reduced or almost completely overcome successfully in animal experiments."

Again, it has lately been shown, in my own laboratory, how important is the balance between fat-soluble vitamins and iodine in the diet. The administration of iodine to rats fed on diets deficient in these vitamins may actually cause goitre (McCarrison, 1930). We have found, also, that the maintenance of an adequate iodine content in the thyroid gland is largely influenced by the content of vitamin C in the food (Sankaran, 1931). Few organs of the body, indeed none with the exception of the suprarenals and thymus, are more profoundly affected by faulty nutrition than the thyroid gland, and few are more sensitive to this influence.

My second lecture will deal with the causation of urinary calculus.

THE TREATMENT OF DYSMENORRHOEA*

BY

B. VENN DUNN, M.D., F.R.C.S.ED.

Recent investigations have facilitated the treatment of dysmenorrhoea on a more rational basis than has been possible in the past. The old classification of dysmenorrhoea into spasmodic and congestive varieties may be discarded for several reasons. In the first place the terms are not relative; "spasmodic" denotes a disorder of function, whereas "congestive" implies a morbid anatomy. Secondly, the two forms cannot be easily differentiated; cases frequently occur each with a different morbid anatomy, all with similar symptoms—those of spasmodic dysmenorrhoea. Thirdly, there is a danger of cases being labelled "spasmodic" without sufficient examination having been made. The importance of a complete investigation of every case of dysmenorrhoea cannot be too greatly stressed.

CLASSIFICATION

The following classification has been found of practical value in the investigation of cases:

1. Psychological.
2. Endocrine.
3. Mechanical.
4. Gross pathological.

The treatment of the patient will vary according to the category to which the case belongs.

THE PSYCHOLOGICAL TYPE

This applies to those patients, often in their teens, but sometimes much older, who have had an unhealthy psychological upbringing. They may, from their earliest years, have had their simplest physiological acts associated with feelings of shame and repugnance. Such an association is bound to make a child magnify any slight discomfort experienced at a time when she is undergoing rapid mental development and in a region she has been told is so important as to be unmentionable. Perhaps, also, too much may have been made of any slight disability the child may have felt in the early months of puberty. The overanxious parent insists on the child lying up when it is more than ever necessary that the circulation in the pelvic area should be encouraged. Gradually a habit of pain becomes formed, the nerve paths for pain become especially sensitive from much use, and, unless a new hygiene is quickly enforced, dysmenorrhoea may continue for the rest of the sexual life.

The treatment of this type of case varies with the age of the patient. The great hope is to catch her young, and before the habit of pain is too well formed. Then we must be ready to spend a good deal of time, first with the patient's parents (either or both) and then with the patient herself. The matter must be talked out. These are the cases which do well under the regime recommended by the Medical Women's Federation, whose leaflet, "Advice regarding menstruation," consists of an exhortation to "business as usual" during the menstrual period. It insists on the necessity of the daily warm bath throughout; it advocates an adequate amount of exercise, while it deprecates "long expeditions and cycle rides or matches or competitions in which there is a strong incentive to exhaust the reserves of strength." The use of a system of physical exercises such as that published a few years ago by Dr. Harold Dearden, under the title of "Exercise and the will," is extremely valuable for these girls. The older patients with this type of dysmenorrhoea are a trouble to their medical advisers as well as a nuisance to themselves. The only people who profit by them are the vendors of patent medicines and the retailers of gin.

* Abstract of a paper read before the Torquay Medical Society on March 19th.

A woman, aged 40, recently presented herself. She had always suffered from violent pain at the periods. There was no apparent abnormality in the pelvis. She had commenced life with a father who idolized her, and a mother who thought she was a nuisance, because the child interfered with her hunting. The sequence of an expensive education, marriage into the Army, childbirth (the child did not survive), colonizing in Africa, and eventually divorce, had failed to subdue the periodic pain. Month by month she retired to bed and subsisted on gin and hot water. After many conversations and much encouragement she is at last beginning to pull herself together and live a more normal life.

ENDOCRINE FACTORS

When we come to discuss the endocrine causes of dysmenorrhoea, the possibilities are numerous, and it is only by keeping strictly to the facts that it is possible to correlate certain definite clinical types with glandular dysfunction. The modern theories of menstruation have recently been well ventilated by Cannon,[1] James Young,[2] Teacher,[3] and others, and it is necessary here to make only a brief survey. The alpha hormone of the anterior pituitary gland stimulates the production of oestrin by the ovary, which in its turn causes congestion of the uterus. This congestion is probably the forerunner of that type of menstruation which occurs without ovulation; it also assists in the more normal type which follows ovulation. The beta hormone of the anterior pituitary stimulates the formation in the ovary of lutein tissue, which governs the preparation in the uterus for nidation and gestation of the fertilized ovum. If fertilization fails to occur the scaffolding is cast off. It is the rhythmic variation in the supply of these hormones which results in menstruation.

Overaction of the anterior pituitary, overproduction of the alpha hormone, and overproduction of oestrin by the ovary may be responsible for that type of dysmenorrhoea which occurs in early developed young women who started to menstruate early and copiously, and who have well-marked secondary sex characters. This class of patient benefits mostly by active elimination during the few days immediately preceding the period. In addition to the exercises and baths recommended in the last section, the administration of magnesium sulphate first thing in the morning for three days prior to the expected period is often productive of very favourable results.

The reverse type to this is the under-developed late-menstruating girl whose flow is scanty and whose interval is prolonged. She has a flat chest and narrow hips, She is good at games and something of a tomboy. There is, we may reasonably suppose, inadequacy of the alpha hormone and shortage of oestrin. We should expect benefit to accrue from the administration of anterior pituitary extract or from oestrin. Three years ago I gave sistomensin in a series of twelve cases of dysmenorrhoea. I was disappointed with the results. Only three out of the twelve showed any definite signs of improvement. I think that may have been because the cases were not definitely selected. Dr. James Young, in a personal communication a few weeks ago, said:

> "With regard to dysmenorrhoea I have been employing sistomensin in the form of two tablets daily for the ten days preceding the onset of the period, and in addition one ampoule hypodermically twice weekly the week before the period. We now have a large number of successful cases so treated."

Interesting in this connexion is the work of Collip and Campbell[4] of Montreal. They have separated the alcoholic extracts of human placenta into three fractions, each having distinctive physiological properties. The second fraction represents 85 per cent. alcohol-soluble material present in the original extract but from which oestrin had been extracted with ether. They call the substance "emmenine," and with it they produced oestrus in immature rats. The action resembled that of the alpha hormone of the anterior pituitary. Applied to the treatment of dysmenorrhoea, twenty-six out of thirty-six cases are said to have been relieved. There has as yet been no opportunity of employing this substance, but the rationale of the treatment is good and its outlook distinctly hopeful in this type of case.

A third endocrine cause of dysmenorrhoea may rest in overaction of the beta hormone with increased lutein action in the ovary. This probably accounts for those cases of dysmenorrhoea described by Beckwith Whitehouse,[5] which he suggested were due to difficulty in disintegration of the surface layers of the endometrium. He believes that the transient exacerbations of pain which are so characteristic are due to the passage of abnormally large flakes of endometrium, and that what is usually called membranous dysmenorrhoea is really just an extreme form of the process which causes pain in the more ordinary cases. The treatment of this type, as in all cases of hyperfunction of the endocrine system, must depend either on drugs or on surgical intervention, and will be dealt with along with mechanically caused cases.

MECHANICAL CONSIDERATIONS

In this group I place cases in which the neuro-muscular mechanism of the uterus is at fault. Now the neuro-muscular mechanism of the uterus displays an interesting property, which has been designated "polarity"—a simple indication that there is a co-ordination of fundal contraction and cervical dilatation. The normal rhythmical contractions are increased in intensity during menstruation; if, then, the cervix fails to follow the lead and dilate sufficiently, the uterus will be thrown into spasm. This is not the only instance in the body where young developing tissue suffers from antagonism in the co-ordination of the neuro-muscular function. An analogy is congenital hypertrophic stenosis, in which there is no actual stenosis of the pyloric canal, and yet the intense spasm of the pylorus refuses to allow the stomach contents to reach the duodenum. In many cases of dysmenorrhoea the uterus is abnormally small, and it has been found that the proportion of muscle to fibrous tissue is low. If, associated with this neuro-muscular deficiency, there is to the outflow from the canal a partial obstruction, due to extreme anteflexion, to contraction of the external os, or to abnormal contents such as blood clot or large shreds of decidua, it is not surprising that the uterus is thrown into painful spasm in its attempt to fulfil its physiological functions.

The difficulty of any cut-and-dried classification is that there is bound to be a certain amount of overlapping, and in this class there are many cases which will benefit from endocrine treatment. In particular, where the faulty mechanism can be associated with other symptoms of thyroid deficiency, I have found that the administration of thyroid in conjunction with other measures has brought about relief. In cases in which the cervix is conical in shape and the os unduly small, dilatation either alone or combined with a plastic operation is the method of choice. To be efficacious dilatation must be sufficient. The cervix should be dilated up to number 14. Further, the patient must be warned that the operation may have to be repeated in three months' time. When operation is refused or is inadvisable, or sometimes as a concomitant to operative treatment, atropine is of considerable value. Commencing two days before the expected onset of the period, 1/200 to 1/100 of a grain should be given three times a day. Symptoms of idiosyncrasy to belladonna must be watched for. The pharmacology of atropine is interesting. Applied to nerve-muscle preparations of the uterus, it increases muscle tone, decreases the amplitude of the contraction, but increases the rate.[6]

Atropine acts on the uterus in the same way that it acts on the intestine—namely, it arrests only certain abnormal violent forms of contraction without interrupting the path of nervous impulses from the spinal cord to the uterus.[7] It therefore aids normal uterine polarity by making the contraction of the fundus more smooth, and at the same time relaxing the spasm of the sphincter muscle at the internal os. In severe cases it is often advisable to combine the antispasmodic with an analgesic and a sedative in the following cachet: luminal 1/2 grain, pyramidon 5 grains, ext. hyoscyamus 1 grain.

In cases where these measures prove unavailing to arrest the complaint there are several others at our disposal. Subtotal hysterectomy must be mentioned only to be condemned as an admission of failure. The recent French work on resection of the presacral nerve is interesting. Binet,[8] in a report on thirty-two cases of pelvic pain, claims that relief is usually secured. He removes the whole of the tissue, including the sympathetic fibres lying between the common iliac arteries. He says it is "a simple operation, easy, and, above all, efficacious." In Germany, Blos[9] has treated dysmenorrhoea by the injection of alcohol. He believes that dysmenorrhoea is due to increased sensitivity of the ganglia governing the uterus. At each side of the cervix is injected 5 c.cm. of 70 per cent. alcohol, containing 5 per cent. novocain. He says that the treatment has given excellent results for ten years, with no harmful effects even on childbearing.

Gross Pathological Conditions

Lastly, there are those cases of dysmenorrhoea which are due to some gross pathological condition. The lesion may be anything from a simple cervical erosion to generalized pelvic cellulitis or new growth. The age of the patient will give no indication whether the pain is due to some functional or endocrine derangement or to organic change. There is only one way in which a correct diagnosis can be made—by a thorough examination of the patient. If the patient is a young woman, often even if she is older, it is necessary to examine her under an anaesthetic. The lithotomy position, and a visual examination of the vaginal vault with speculum and terminal mirror, followed by a careful palpation of the uterus and adnexae, are the minimum necessities. The following case is of interest:

A young woman, aged 15, recently presented herself. She was remarkably developed for her age. The secondary sex characters were those of a well-developed woman. She complained of right iliac pain accompanying her periods; indeed, so definitely was the pain localized that her appendix had already been removed. She first menstruated at 11 years of age, her periods occurring every twenty-one days. The pain began the day before the period; it was spasmodic in character, lasted for two days, and then gradually subsided. On examination under an anaesthetic, the left ovary was found to be replaced by a cyst the size of a cricket ball, while the right ovary was enlarged and prolapsed into the pouch of Douglas. At the operation, the cyst was removed, and the right ovary (which was very congested and more than twice its normal size) was stitched into a pocket in the peritoneum. There has been no return of the disability. I quote this case to illustrate the absurdity of attempting to treat dysmenorrhoea from a symptomatic point of view. The patient had already been treated with an oestrin preparation, though it was quite obvious that she was sexually overmature, and that endocrine treatment could do nothing but harm.

MINOR SURGERY OF INFANCY*

BY

DAVID LEVI, M.S., F.R.C.S.

ASSISTANT SURGEON TO THE INFANTS HOSPITAL, VINCENT SQUARE, LONDON; SURGICAL REGISTRAR AT THE ORTHOPAEDIC HOSPITAL

As we treat children until the age of 5 years in this hospital the following remarks are only applicable up to that time of life. There are many minor surgical conditions with which one is faced during the period of infancy. I have chosen a few of these conditions, and will describe a simple method of dealing with each.

Herniae

Hernia is very common in infancy. Large numbers of children are born with inguinal and umbilical herniae. The treatment of umbilical herniae has, in the past, usually been carried out by physicians. These learned gentlemen took great pride in strapping halfpennies, suitably covered with lint, over the protuberant umbilici

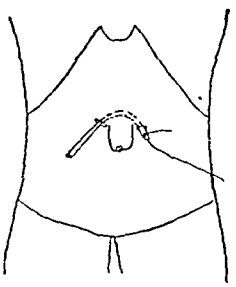

FIG. 1.

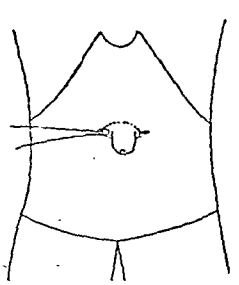

FIG. 2.

FIG. 1.—Aneurysm needle being passed subcutaneously round the neck of the hernia.
FIG. 2.—The ligature in place before it has been tied.

of the stream of infants constantly passing before them in the out-patients' department. Given patience, persistence, and perseverence, this method eventually leads to the disappearance of most umbilical herniae. I have recently ligated the neck of the sac of these umbilical herniae subcutaneously, with the result that the hernia is cured in five minutes instead of the more usual five months. The procedure is simple in the extreme. A local or general anaesthetic is administered and a small stab is made through the skin at the base of the hernia. A blunt aneurysm needle is passed through the stab wound, and, subcutaneously, round the neck of the sac. It is brought out at a diametrically opposite point on the skin through another stab incision. The needle is threaded with a piece of No. 2 catgut and is withdrawn. The needle is inserted through the original stab incision and worked round the base of the sac in the opposite direction, brought out at the second incision, and threaded with the remaining end of the catgut. When the needle is withdrawn a catgut loop surrounds the base of the hernial sac, which is then grasped and squeezed to make certain that it is empty. The ligature is tied. The stab wounds are so small that it is not necessary to stitch them, and they are sealed off with a dressing of Whitehead's varnish. I am indebted to Mr. Boyd for suggesting this method of dealing with these herniae, and I have successfully treated a number of infants by the technique described above.

Inguinal herniae in infants are treated by operative means. The operation for inguinal hernia in an infant, provided that the testicles have descended, is no more than a subcutaneous ligation of the neck of the sac of

* A lecture delivered to post-graduates at the Infants Hospital, Vincent Square, London.

the hernia. The operation is undertaken as soon as the hernia is diagnosed ; the earlier the better. It is performed in the out-patients' department, and the infants are sent home afterwards. Before these infants are operated on, conditions tending to produce increased intra-abdominal tension are remedied. A phimosis or a pinhole meatus is rectified and allowed to heal before the herniotomy is attempted. A temperature, diarrhoea, or rash upon the skin contraindicates operation. The child is neither purged nor starved, but is given an anaesthetic two hours after its last feed. A small incision is made through the skin over the external abdominal ring of the affected side. The coverings of the cord are incised, the sac isolated, and the vas deferens separated from it. This latter procedure requires care, and the vas must not be touched with the forceps. It is often closely adherent to the posterior wall of the sac. When the sac has been isolated it is opened and a probe passed down it into the abdomen. The sac is then twisted, its neck ligated, and the redundant portion removed. The stump drops back from view. The skin incision is closed by means of two silkworm-gut sutures and the wound sealed with gauze and Whitehead's varnish. Only one side is operated on at a time if the child is to be treated as an out-patient.

HYDROCELES

Infants are subject to many types of hydrocele. But in so far as the injection treatment of this abnormality is concerned there are three types: the open hydrocele—that is, one which communicates with the abdomen and which therefore gets larger by night but tends to disappear when recumbency is assumed ; the closed hydrocele—that is, one which does not communicate with the abdomen ; and, lastly, the hydrocele associated with a hernia. The closed hydrocele is the only type suitable for injection treatment. The open hydrocele is not injected on account of the possibility of some of the injection fluid escaping into the abdominal cavity and producing adhesions there. The hydrocele associated with a hernia is dealt with when the herniotomy is performed. Hydroceles in infancy have very thin walls, and the vas deferens is very closely applied to the outside of the hydrocele. If an irritant is injected into the interior of a hydrocele with the object of producing a mild aseptic inflammation, it is not unreasonable to suppose that the inflammation might spread to the closely adjacent vas deferens and produce stenosis or stricture of it. It has therefore been my practice never to inject both hydroceles in bilateral examples of this condition. The procedure is simple. The apparatus consists of a 10 c.cm. syringe with a hypodermic needle, a sterile 1 c.cm. syringe, a sterile 5 per cent. solution of sodium morrhuate, and of swabs and iodine. The 1 c.cm. syringe is filled with sodium morrhuate and the needle attached to the 10 c.cm. syringe. The scrotum is painted with iodine and the needle plunged into the upper and front part of the hydrocele. The contained fluid is aspirated. The 10 c.cm. syringe is detached from the needle and the loaded 1 c.cm. syringe substituted. The sodium morrhuate is injected and the needle withdrawn. No anaesthetic is required, and the operation takes only a couple of minutes. The hydrocele disappears without discomfort or any other noxious effects.

MINOR DISORDERS OF THE FEET

When an infant commences to walk perhaps the most frequent fault found by its mother is that it turns in its toes. This is in itself not a bad sign. When an infant stands it does so on a broad base, with its feet widely separated. The arches of the foot are undeveloped and the toes are pressed firmly downwards on the ground. As the child discovers its balance it brings its feet nearer together, and eventually walks, placing one foot in front of the other. Its weight, which originally was transferred to the ground along the inside of the foot, now passes mainly through the outer side. The child who thus starts walking by stumping along soon develops a spring in its gait and rises on its toes as it takes a step. From the moment the toes are used in this way the internal longitudinal arch of the foot commences to develop.

The minor disorders of the feet in infants are a failure or delay either in the development of the longitudinal arch, the apposition of the feet, or in the presence of a hypermobile foot. When the development of the longitudinal arch is delayed the child walks flat-footed. In its unconscious attempt to throw its weight on the outer side of its feet, it turns in its toes. This in-toeing is a sign that the child is compensating for the tardiness of the development of the arches of its foot, and therefore this should be encouraged. A wedge of one-sixth of an inch should be inserted between the heel and the upper on the inner side of the shoes. The shoe itself should measure at least two sizes larger than the foot, should have a flexible sole, and must have a heel. Wedges and stiffening should not extend into the sole, for the object of treatment is to get the child to rise on its toes in walking and thus develop its longitudinal arch. A stiff sole not only prevents this but tends to throw the child's weight on to the inner border of its foot, thus defeating the objects of the treatment. Most patients react to these simple measures. In severe cases, a valgus insole may be required, together with re-educational exercises. The exercises must not take the form of a ritual to be performed for ten minutes before the child says its prayers each night, but must be directed towards altering a habit. The mental atmosphere created by a skilled masseuse is as important as the physical manifestations of her energies.

Delay in bringing the feet into apposition will result in the development of knock-knee. In these children there is usually an underlying rickety condition which must receive attention. If the knock-knee is mild in degree—that is, if the internal malleoli are one inch or less apart when the internal condyles of the femur are touching, and the legs are extended, then a one-sixth-inch wedge on the inner side of the heel should be prescribed. For more severe degrees of this condition splints suitably applied will usually remedy the fault.

Many infants have hypermobile feet, and this is a potential source of weakness. If an infant's foot can be dorsiflexed so that the dorsum of the foot touches the anterior aspect of its leg, then there will be delay in the development of the normal stance. These infants should have their feet splinted in inversion. A small malleable splint made of one of the light metals and covered is the measure we adopt here. The child should be watched during the period when it is learning to walk, so that supports may be ordered if required.

In older children a mild degree of shortening of the tendo Achillis will often produce a flat-footed gait. A normal foot can be dorsiflexed in the mid-line with the knee straight, so that a plumb-line dropped from the ball of the big toe will pass half an inch or more proximal to the plantar surface of the heel. To carry out this test the foot must be held absolutely median, and allowed neither to go into inversion nor into eversion. If the foot can only be flexed to the right angle there is a mild degree of shortening of the tendo Achillis, and in order to flex the foot further the child everts its fore-foot. This condition of pes valgus may be treated by raising the heel of the shoe half an inch, a measure which takes the strain off the tendon. The tendo Achillis should be passively stretched by the masseuse, and actively by the performance of suitable exercises. It is hardly ever necessary to tenotomize the tendo Achillis for this contracture in infancy. A masseuse can usually stretch the tendon sufficiently to overcome all symptoms.

AN ANAESTHETIC SCREEN, NEEDLE, AND THIMBLE AS "SURGICAL AIDS"

BY

SIR W. I. DE C. WHEELER,

DUBLIN

The anaesthetic screen (Fig. 1) was designed in the first instance for goitre operations. Often when removing the thyroid gland the upper pole is found at a high level, and the orthodox anaesthetic screen comes in the way of the surgeon's wrist and forearm. The screen is useful also in general work when no other anaesthetic screen is available, and in emergency operations (such as tracheotomy) undertaken in a private house. It is adjustable, and fits on to the head. The patient can neither see nor hear, which is an advantage when local anaesthesia is employed.

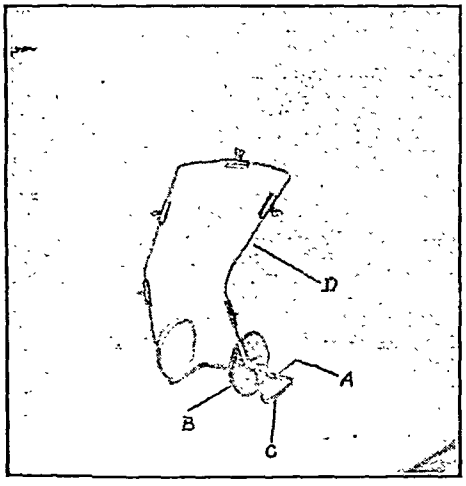

FIG. 1.—A, plate for sandbag; B, circular pads to grasp head about the ears; C, sliding frame; D, wire screen.

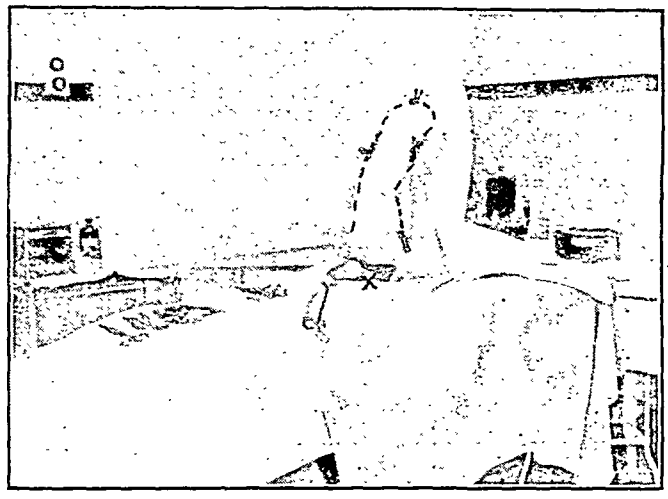

FIG. 2.—Screen in position. X = goitre. The dotted line indicates the wire covered with gauze. A towel is held up for photographic purposes.

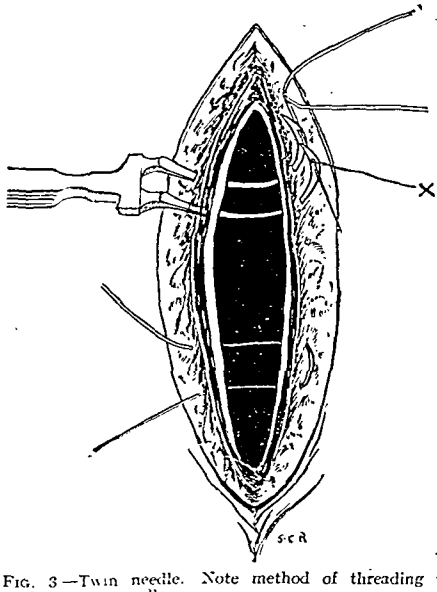

FIG. 3.—Twin needle. Note method of threading with straight sewing needle.

A towel is first wrapped round the head; the padded pieces (B) are placed in position over the towel and adjusted so that the head is grasped firmly. A sliding slot arrangement in connexion with the steel support (C) permits adjustment. A flat piece of metal (A) projects behind, and a sandbag rests on this to secure immobility. The frame (D) acts on a swivel, and can be moved backwards or forwards.

When the screen is in position the patient's head is raised, and two superimposed sterilized sheets are placed under the neck. The superficial sheet is carried round the ear-pieces and the patient's head. The second sheet is brought round the neck in shawl-like fashion and secured to the sheets covering the patient. A gauze "wipe" of double thickness is thrown over the screen and fastened by "paper clips" (Fig. 2).

The screen is very light and portable. It is made by Messrs. Weiss and Co., Oxford Street, London.

Twin Needle

The needle illustrated is of the Doyen variety. The handle carries twin needles. The standard pattern is so designed that a Halsted suture can be quickly introduced through the deeper layers of the abdominal wall in cases where difficulty is experienced in fat subjects or when laxity cannot be obtained. The eyes are sufficiently large to allow the passage of a straight needle for threading purposes (×, *Fig. 3*).

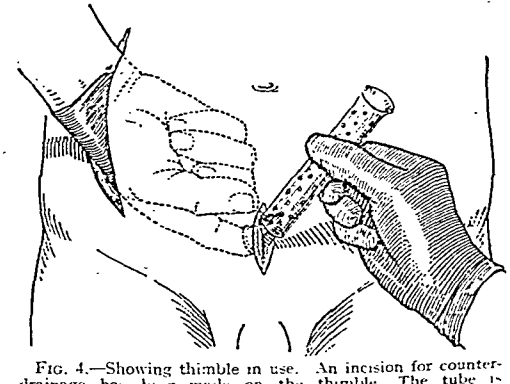

FIG. 4.—Showing thimble in use. An incision for counter-drainage has been made on the thimble. The tube is placed in position and guided to the bottom of the pelvis. (Wheeler's *Operative Surgery*.)

When the catgut is in position the loop between the two eyes should be pulled out several inches before withdrawing the needle. Otherwise withdrawal is difficult, and the catgut may become frayed. Fig. 3 shows one *suture in* position and the needle being threaded for the introduction of a second.

The twin needles are made in several sizes, and with varying spaces between the two. They are supplied by Messrs. Down Bros., London.

Thimble Guide

A thimble on the first finger acts as a guide on which a quick opening may be made for counterdrainage in cases of septic peritonitis (Fig. 4). The model now recommended is made by Weiss. It should fit the finger tightly. When the hand is passed from the main incision within the abdomen towards the suprapubic region the thimble is kept closely applied to the deep aspect of the abdominal wall, so that there is no possibility of a loop of small intestine being pushed forward and injured by the knife. A small incision is rapidly made on the finger guarded by the thimble ; a tube is slipped over the top of the thimble and guided to the bottom of the pelvis by the hand. The illustration depicts a glass tube ; a rubber variety is now more commonly employed. The thimble is of use in many situations (such as the axilla after breast amputation) where counterdrainage is needed.

PERFORATED TYPHOID ULCER

NOTES ON THREE SUCCESSFUL CASES

BY

J. B. G. MUIR, M.B., B.S., F.R.C.S.,

AND

S. C. CHIA, M.B., B.S.

THE KAILAN MINING ADMINISTRATION, TANGSHAN, NORTH CHINA

Perforation of typhoid ulcer occurs as a complication in about 3 per cent. of all cases of the disease, and, according to various authorities, accounts for approximately 30 per cent. of the total mortality. There is but one form of treatment—namely, operation as soon as possible. This is attended by a very high death rate. Harte and Ashhurst,[1] in their classical paper on this subject, based on a large series of cases, quote it as 74 per cent., with decided increases depending upon the twelve-hour periods elapsing between the occurrence and surgical intervention. The rate is distinctly lower in children, being given as 50 per cent. by Jobson and Gitting,[2] and as 36 per cent. by Elsberg.[3]

CAUSES OF HIGH MORTALITY

The factors responsible for this high mortality may be summarized as follows:

1. The catastrophe occurs generally during the second to third week of the disease, when the patient's general condition is at its worst, with severe toxaemia and a weak and dilated heart as contraindications to the necessary shock attending surgical intervention.

2. Occasionally it is very difficult to make a diagnosis of actual perforation, particularly in cases where great abdominal discomfort, pain, and distension have been dominating symptoms from the onset of the disease. (In such cases, however, a leucocytosis will always indicate the onset of peritonitis, and in any event it is probably better to submit even a weak and debilitated patient to the risk of laparotomy than to overlook a perforation until it is too late.)

3. The perforation may be complicated and temporarily masked by the simultaneous occurrence of intestinal haemorrhage from the separation of sloughs.

4. As a general rule, in cases of perforated typhoid ulcer, infection of the general peritoneal cavity by the extravasated intestinal contents is present from the first, with the formation of a watery exudate, and with little attempt at localization, or the formation of adhesions. (This was a feature of Cases I and II, described below.)

5. Difficulty is frequently experienced in suturing the perforation owing to the inflamed and friable condition of the bowel caused by adjacent ulceration. This has led some surgeons to treat the condition by passing an enterostomy tube through the perforation, fixing it *in situ* by a catgut stitch, and contenting themselves by draining the affected loop of bowel. Two successful cases treated in this way have recently been published by Branch.[4]

6. Occasionally perforations may be multiple, two, or even three, being present, and the necessary handling of the intestine during the operation may cause the perforation of adjacent ulcers.

7. Leakage frequently occurs, after apparently successful suture, resulting in the formation of a faecal fistula. These possibilities (Nos. 5, 6, and 7) have caused Roux-Berger,[5] Cadenat,[6] and others to treat the perforated loop of bowel by exteriorization, in addition to suture or enterostomy, but this method does not appear to have lowered the mortality.

8. Pulmonary complications, notably pneumonia, are common sequels of the operation.

THE HIGH DEATH RATE IN CHINA

In China the mortality tends to be still higher, as, in addition to the above considerations, there is the fact that the majority of patients wait until their conditions are literally hopeless before submitting to operation. An interesting point in the local occurrence of the disease has been observed by Loucks,[7] who considers that in some years typhoid infections show a much greater virulence than in others, and that there is then a much higher incidence of perforation. In view of these facts, the first and second cases here described are encouraging in that twenty and forty hours elapsed respectively between perforation and operation, which was successful, and the third case is interesting as illustrating how localization of a typhoid perforation in a hernial sac may simulate a strangulated inguinal hernia.

CASE I (J. B. G. M.)

Perforation of typhoid ulcer, with operation twenty hours after onset: recovery.

L. W., aged 11, daughter of a Chinese merchant, was suffering from a severe attack of typhoid fever (Widal ++). On September 15th, during the third week of the disease, she was suddenly seized with acute pain in the lower abdomen, with vomiting, and became very collapsed. Her medical attendant, Dr. T. J. Hua, saw her half an hour later, when abdominal distension and rigidity were becoming apparent, and diagnosed perforation of a typhoid ulcer, a diagnosis which was subsequently confirmed by two colleagues. Operation was advised, and after considerable discussion consent of the family was obtained ; I was eighty-five miles away when telegraphed for. Unfortunately, owing to infrequent trains, I was unable to arrive before 6.30 the following morning. During this time the patient was kept in the Fowler position, continuous "drip" rectal saline containing 5 per cent. glucose was administered, and 5 minims of tincture of opium was given by the mouth four-hourly. I performed laparotomy, under open ether anaesthesia, at 7 a.m. on September 16th, twenty hours after the perforation had occurred. A large quantity of seropurulent fluid escaped from the abdomen when the peritoneum was opened, but there was surprisingly little congestion or lymphatic exudation on the intestinal coils. A small circular perforation in the base of an ulcer was found, situated on the free border of the ileum, about 8 inches from the caecum, and was closed by invaginating purse-string sutures of chromic catgut. The extravasated fluid was thoroughly mopped up, and the abdomen was closed with a large pelvic drain *in situ*, the whole proceeding occupying only eight minutes. The child suffered from severe shock, and her condition was very grave for about twenty-four hours, when she began to rally, and made

a good recovery. Her convalescence, though protracted, was very satisfactory, despite a small faecal fistula which persisted at the site of the pelvic drainage tube for about a month before closing spontaneously.

CASE II (S. C. C.)

Perforation of typhoid ulcers complicating pregnancy, with operation forty hours after onset: recovery.

L. H. A., aged 28, wife of a Chinese military officer, was admitted to hospital on November 18th, 1930, with the following history. She had been ill for twelve days, suffering from fever, headache, and abdominal discomfort. Following the ingestion of a herbal remedy recommended by a native "medicine man" she was seized with acute abdominal pain on the evening of November 16th. She vomited several times at the onset of the attack, and became very collapsed. The native practitioner treated her with morphine injections, but as her condition was rapidly becoming worse her relatives brought her to hospital at 6 p.m. on November 18th, forty hours after the onset of the acute pain, and, presumably, of the occurrence of perforation. The case was complicated by the fact that the patient was five months pregnant, but as it was obvious that peritonitis was present and that the patient was *in extremis*, I performed immediate laparotomy. On opening the peritoneum a quantity of gas escaped, with a lot of thin seropurulent fluid. The pregnant uterus filled the entire pelvis, and the inflamed and congested intestine, with considerable lymphatic exudation on the surface, appeared to occupy the entire abdomen. Two perforations were found on the free border of a coil of the ileum, about 12 inches from the caecum. They were about 2 inches apart, and were each closed with some difficulty, owing to the extreme friability of the bowel, by purse-string catgut sutures. Thorough irrigation of the entire peritoneal cavity was then carried out, using several pints of warm normal saline, and the abdomen was closed, three large tubes being left *in situ*, draining both flanks and the mid-line. The patient's condition was exceedingly grave for two days following operation, severe abdominal distension being present, but turpentine enemas caused the bowels to act on the second day, with considerable relief of symptoms. Matters were further complicated by the occurrence of a miscarriage on the third day following operation, a five-month foetus being expelled. The patient's condition however, did not seem to be greatly impaired by this mishap. On the eighth day following operation a severe attack of broncho-pneumonia developed, and for several days it was thought that this would prove a fatal complication. After several weeks' illness, however, the patient slowly recovered, and was discharged in good health from hospital eleven weeks after admission.

Consideration of these two histories makes it clear that it is never too late to operate in a case of perforated typhoid ulcer, as even the apparently hopeless patients (vide Case II) may possess amazing recuperative powers. An interesting and common feature to both cases was the thin, watery character of the peritoneal exudate, with flakes of yellowish-white lymph—not nearly so offensive as the exudate in many types of appendicular peritonitis. Unfortunately in Case I no bacteriological examination was made, but in Case II smear and culture showed staphylococci and Gram-negative bacilli.

Harte and Ashhurst,[1] in considering the bacteriology, have pointed out that the prognosis is graver if the streptococcus is the predominating organism, as, in cases in which the typhoid bacillus alone is the infecting cause, the peritonitis is of a relatively low-grade type, with a watery exudation and few adhesions. It is probable, therefore, that the successful results in these two cases were largely influenced by this factor.

CASE III (J. B. G. M.)

A Chinese casual labourer, aged 32, suffered since boyhood from a right inguinal hernia, which had latterly increased considerably in size, but, as he somewhat graphically put it, he could push his bowels back into his stomach when he lay down. On October 2nd, 1930, he was admitted to the Tongshan Base Hospital as a case of strangulated inguinal hernia. The history was that for the preceding fortnight he had been feeling unwell, suffering from headache, some diarrhoea, fever, and swelling of his stomach. Several days before admission he had experienced a good deal of pain in his hernial swelling, and found that it could not be reduced. He used considerable force in attempting reduction on the day of admission, and the pain became exceedingly severe. The inguinal swelling was very tense, with the skin over it very red, and the patient's condition simulated intestinal obstruction due to strangulation of the inguinal hernia. Immediate operation was advised and agreed to. On incising the sac much purulent fluid escaped, and a coil of ileum, about 18 inches in length, was seen to be incarcerated. It was very swollen and congested, but obstructed rather than strangulated. A small round perforation was present on the free border of the coil, through which the extravasation of intestinal contents had occurred, and several ulcers could be palpated along the free border of the bowel. The perforation was closed by an invaginated purse-string suture, the intestinal loop carefully washed with warm saline solution, and the loop of bowel returned to just within the abdominal cavity. A large drainage tube was inserted through the neck of the sac down to the sutured perforation, and the patient returned to bed. A subsequent blood examination gave a strongly positive Widal reaction, and the later course of the case was that of typical typhoid fever. A radical cure was performed for the hernia two months later.

In this case the hernia was undoubtedly rendered irreducible by the inflammatory swelling and infiltration of the Peyer's patches in the herniated bowel, as a consequence of typhoid. It was indeed a lucky coincidence that the perforation occurred in the hernial sac rather than in the general peritoneal cavity, although it is quite probable that perforation was induced by the patient's own attempts at reduction of the inflamed bowel.

TUBERCULOUS PERITONITIS SIMULATING COELIAC DISEASE

BY

E. C. WARNER, M.D., M.R.C.P.

PHYSICIAN TO THE CHILDREN'S DEPARTMENT, THE MILLER GENERAL HOSPITAL; PHYSICIAN WITH CHARGE OF OUT-PATIENTS, THE DREADNOUGHT HOSPITAL, GREENWICH

In view of the interest aroused in coeliac disease by the excellent review of Leonard Parsons,[1] and by the theory put forward by Ryle[2] that the essential cause is an obstruction of the lacteals by previous inflammation, it seems opportune to record a case recently under my care in the Miller General Hospital, which closely mimicked coeliac disease, and in which extensive tuberculous peritonitis was found at necropsy.

CASE HISTORY

Mary O. was first referred to me by Dr. Rogerson of Bexley Heath, on account of diarrhoea, abdominal enlargement, and wasting. In this family the seven other children were healthy. At birth she was a full-term baby weighing 6 lb., and she was breast-fed. She remained well till two months before I first saw her, when, at the age of 2 years and 4 months, she began to get periodic attacks of diarrhoea with occasional pale stools, associated with loss of weight, feverish turns, whining, abdominal enlargement, and occasionally prolapse of the rectum. At no time was there any

abdominal pain or vomiting. On examination she was evidently small for her age. Her weight at the age of 2½ years was 17½ lb., and her height 30 inches (average normal 33 inches). She was very wasted, the limbs being much more so than the abdomen and face. There was but little subcutaneous fat anywhere; there was marked wasting of the gluteal region, so that the prominence of the buttocks had almost disappeared and the skin hung in folds. There was definite loss of tone in the muscles, producing a dorsal kyphosis. In contrast to this wasting the abdomen was enlarged (girth at umbilicus 18 inches). There were no signs of free fluid, but gaseous distension was so marked that coils of gut could occasionally be seen through the abdominal wall. Palpation did not give the characteristic doughy feel of tuberculous peritonitis, and careful examination did not reveal any enlarged or palpable abdominal glands. Rectal examination was also negative. The sclerotics were of rather light blue colour, with the particularly brilliant reflection from them so often associated with hepatic disorders. The bony skeleton showed some evidence of rickets, as the radial epiphyses were enlarged, the tibiae rather bowed, the head bossed, and there was beading of the ribs. She was also evidently anaemic.

There were anything up to five stools a day, the average being two to three. They were large, bulky, very offensive and pale, with evident excess of fat and some excess of mucus. This was confirmed by microscopical examination, which showed a large excess of split fat to be present. The stools were alkaline (*p*H 8.0). Cultivations showed the presence of *B. coli* and *Streptococcus faecalis* only. *X*-ray examination of the abdomen failed to reveal any opacities suggestive of tuberculous peritonitis. A blood count showed haemoglobin 50 per cent.; red cells, 4,700,000 per c.mm.; colour index 0.5; white cells, 10,800 per c.mm. During the whole of her time in hospital she ran an irregular pyrexia; some days the temperature was normal, while at other times the rectal temperature would rise to 104°. For periods of two to three days, with the larger rises of temperature, she was fretful, the abdominal distension became much more marked, and the stools more offensive, copious, and still more fatty. In between these bouts the condition would settle down to the quiescent phase. She also exhibited the mental characteristics of cases of coeliac disease. During her brighter periods she looked precocious in proportion to her size, and took an intelligent interest in what was being said about her, although saying very little herself. Her appetite was capricious.

She was given a considerably reduced fat diet in accordance with the usual plan in these cases; the protein was increased, and irradiated ergosterol and ultra-violet light were administered. To control the diarrhoea, silver nitrate and, later, kaolin were given. Under this regime the abdomen became smaller, the stools became much less offensive and firmer, and the fat largely disappeared. In spite of this her general condition did not improve. She slowly lost weight, became very anaemic, and continued to get periods of pyrexia. Later, streaks of blood and some pus appeared in the stools, in which starch granules and excess of meat fibres were present. Treatment with pancreatic ferments and bile salts combined with a blood transfusion were unavailing. Towards the end she became drowsy, and marked oedema of her face and legs occurred. When she died at the age of 2 years and 10 months her weight had fallen to 12 lb. 12 oz.

POST-MORTEM FINDINGS

Dr. W. Smith, pathologist to the Miller General Hospital, made the following observations. There was much wasting of the arms and gluteal regions of an emaciated child. Recent adhesions surrounded the whole of the right lung, in which small areas of consolidation were present in all lobes, more marked in the upper lobe; the left lung appeared normal. There were no obviously enlarged glands in the mediastinum; the heart muscle was good, with slight right-sided dilatation; the liver showed some degree of venous engorgement. The intestines were matted together and adherent to a large mass of mesenteric glands involving the whole of the mesentery; caseation was present in many. Section of the glands revealed the typical appearances of tuberculous disease, with areas of caseation and giant cell systems. Similar changes, and also large areas of lymphocytic infiltration, were found on histological examination of the lungs.

COMMENTARY

This case showed all the classical symptoms and signs of coeliac disease. The patient was a girl (Still states that coeliac disease is nearly twice as common in girls as in boys), who developed the disorder at the age of 2 years and 4 months (Still gives the limit of age of onset in his series as 8 to 38 months). There was marked hypotonia and wasting, especially of the glutei—described as typical of coeliac disease by Reginald Miller. The stools were large, bulky, pale, mucoid, and offensive, and consisted largely of split fat in the form of soaps and fatty acids. The abdomen was much distended with gas. The mental state was typical of the coeliac child, and there was a tendency to rickety changes in the bones, a point stressed by Leonard Parsons. A variation in the patient's condition every few days is often found in coeliac disease, as are also the secondary anaemia and the rather low white cell count; and some oedema of the face and extremities is not unusual. An irregular pyrexia is often present in the diarrhoeic form of coeliac disease (R. Miller). The picture seemed complete, as there was no radiological evidence of diseased abdominal glands, yet at necropsy an extensive tuberculous peritonitis was found, without any calcification in the glands. The only points that were in favour of a diagnosis of tuberculous peritonitis in this case were the height of the pyrexia and the rather rapidly fatal termination of the disease.

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

PERFORATION OF GASTRIC ULCER THREE AND A HALF YEARS AFTER GASTRO-ENTEROSTOMY FOR PERFORATING DUODENAL ULCER

This case seems to me to be of sufficient interest to put on record as an unusual sequel of gastro-enterostomy.

The patient, a male, first came under my care on July 28th, 1927, at which date he was 44 years of age. He had a small perforation of the anterior wall of the duodenum, and gave a six months' history of pain after meals. I sutured the perforation, and performed posterior gastro-enterostomy. Recovery was uneventful.

In reply to a follow-up inquiry in September, 1930, he wrote to the effect that he had been under his doctor recently with gastritis, but that the condition had cleared up.

On January 28th, 1931, he was again admitted to hospital with symptoms of perforation. Laparotomy showed the duodenum apparently normal, the gastro-enterostomy in perfect order, and an indurated ulcer of the lesser curvature of the stomach, proximal to the stoma, which had perforated. I repaired the perforation, removed the appendix, and drained the pelvis. Recovery was again rapid.

X-ray examination of the stomach about three weeks after the second operation showed that food passed very rapidly through the gastro-enterostomy opening.

The patient was a fairly healthy-looking man of spare build. Most of his teeth had been extracted. He was said to have a partiality for alcohol. He told me that he was

free from stomach trouble for nearly three years after the first operation.

The patient was readmitted to hospital in May, 1931, suffering from a subphrenic abscess, to which he succumbed.

In the B.M.A. investigation into the after-history of gastro-enterostomy there were 995 cases in which the operation had been done for duodenal ulcer. In only three of these was there a history of subsequent gastric ulcer, and in none of these did perforation occur.

KERATODERMIA BLENNORRHAGICA

The following note may be of interest. In spite of the fact that a gonococcal infection has not been discovered, I believe this to be a case of keratodermia blennorrhagica, which is somewhat rare in women.

Mrs. N. T., aged 30, the wife of a dairyman, was admitted to the Gloucestershire Royal Infirmary on January 23rd, 1930. The history was that for three months she had pain and swelling of the feet, followed by a similar condition in the knees, which had lasted for three weeks. There was a rash, which was most marked on the feet and legs. She had two children, but had experienced no difficulty at her confinements. On admission she appeared very ill, being pale, cachectic, and emaciated. The tongue was dry and dirty, the lower teeth were very septic, and the right tonsil was enlarged and appeared also to be infected. Both knees were swollen and painful. Around the toes of both feet and on the soles were large heaped-up masses of hard irregular horny skin. On the legs the whole area from the knees downwards was covered with (*a*) small pink papules, the largest 1/4 inch in diameter, gradually changing to (*b*) orange-brown papules, and (*c*) papules with scaly horny tops, which as they enlarged became limpet-like and of a grey colour. Some of these were nearly three-quarters of an inch in length; on removal they

did not leave a raw surface. The three types of lesion became less numerous on the thighs, and only a very few hard scaly papules with sharp tops occurred on the abdomen, chest, arms, and palms of hands. The temperature was never above 100.8° F., but the pulse kept in the vicinity of 100 until convalescence was well established. No abnormal physical signs or symptoms were detected in other organs. The Wassermann reaction of the blood was negative. The urine was sterile. A swab from the cervix did not show gonococci, but there were some streptococci and staphylococci. The faeces showed marked increase of the faecal streptococci. From the throat a non-haemolytic streptococcus of the *viridans* type was isolated. From the pus in a few skin lesions the *Staphylococcus aureus* was grown. A history of gonococcal infection could not be obtained.

The early treatment consisted in feeding the patient and giving mercury, iodide, and arsenic, but there was no improvement. A gonococcal vaccine and boric acid starch poultices were then tried, the arsenic being continued. She very rapidly improved, and left hospital on May 3rd with no rash, with increased weight, and good colour. She was, however, unable to walk. To-day she can do this, but she has very flat feet, which are tender; otherwise her health is good.

My thanks are due to Dr. Davey of the Gloucestershire Infirmary for his help in the bacteriological investigation of this case.

D. E. FINLAY, M.B., B.S.,
Gloucester. Physician, Gloucestershire Infirmary and Eye Institution.

Reports of Societies

SENSORY MESSAGES

The Croonian Lecture before the Royal Society was given, on June 4th, by Professor E. D. ADRIAN, F.R.S., who took as his subject the messages in sensory nerve fibres and their interpretation. He said that by amplifying the electric changes which took place in the individual nerve fibres it was possible to record the messages which passed from the sense organs to the central nervous system and from the motor nerve cells to the muscles. It was found that a series of brief potential changes travelled along each nerve fibre; the changes were of fixed intensity and duration, but their frequency varied with the intensity of the excitation. Each potential change represented a nerve impulse of the type made familiar by the classical methods of electrophysiology. Reasons were given for the belief that all nervous communication was carried out by such impulse messages, and that the impulses, like the electric changes which accompanied them, were unaffected by variations in the intensity of the stimulus. The general similarity of motor and sensory messages made it probable that the sensory nerve endings and the synaptic regions of the central nervous system worked on a common plan depending on the fundamental properties of excitable cells. The sensory messages which had been most thoroughly investigated

were those produced by the muscle spindles. Those from the skin receptors, though less easy to analyse, were of greater interest to the physiology of sensation. At present the most definite results had been obtained from the frog. The frog's skin contained receptors which responded to light contact with a brief discharge of impulses travelling in nerve fibres which conducted rapidly. A vibrating stimulus gave a series of impulses with the same frequency as that of the stimulus, but discharges of high frequency and long duration from these receptors did not give rise to pain. Firm pressure at certain points gave a continued discharge of rapid impulses with a declining frequency. The receptors probably differed from those responding to light touch, though both were in the superficial layers of the skin. Stimuli which would be likely to cause continued pain gave rise to impulses of small action potential travelling in fibres, which conducted very slowly (about 1 metre a second). In the mammal, as in the frog, light touch produced a brief discharge of impulses of large potential conducted rapidly, and firm pressure gave a continued discharge. Impulses of smaller potential conducted at slower rates were produced by movement of the skin, and persistent discharges often arose from exposed tissues. At present it appeared that some of these impulses were caused by stimuli which would not necessarily be painful. A comparison of these results with those of Gassa and Erlanger and of Piéton showed that the nerve fibres responsible for pain were not all of the same type, though they were all of smaller diameter than the tactile fibres. The lecturer suggested that the rate of reaction and amount of conveyance in the sensory pathways were important factors in determining the intensity of sensation, since this must depend on a summation of the effects of discontinuous impulses.

MENTAL DISORDER AND PERNICIOUS ANAEMIA

At the quarterly meeting of the Royal Medico-Psychological Association, held on May 21st at B.M.A. House, Tavistock Square, London, under the presidency of Dr. T. SANTY GOOD, Dr. NORMAN R. PHILLIPS read a paper on mental disorders associated with pernicious anaemia.

Dr. Phillips said that Continental observers especially had shown that mental disorder was frequently met with in association with pernicious anaemia. In the milder mental disturbance there might be no more than a modification of character, chiefly shown in irritability and unstable moods. When the mental state was more pronounced, it was usually of the paranoid type, with delusions of persecution and suspicion, directed chiefly against those who were looking after them. Cabot found delirium in 44 per cent. of his cases of pernicious anaemia. At night the patient had terrifying hallucinations, with great agitation and restlessness; his reaction to these was to become grandiose, abusive, aggressive. The mental syndrome resembled that of toxic psychoses, and so it stood that the testamentary capacity of the questioned. The period of the illness change might be evident varied. led as a terminal condition, but it could occur at any stage in known to supervene while the the mental symptoms mia, it was easy to might be labelled anaemia not underlying several cases quoted series figures improvement following liver

Professor G. M. ROBERTSON said that during his career he had seen many cases of chronic mental disorder developing in the course of pernicious anaemia, but recently he saw a case of that disease in which mental symptoms of acute degree developed early. There had been the usual symptoms of general weakness and gastric trouble, with a suspicion that cancer of the stomach might be present. Then the patient began to get rather feeble-minded, with suspicions, and quarrelled with the daughter who looked after him. After he had been in a nursing home several days he developed an acute delirious attack following anxiety. He was certain he would be injured, was noisy and delirious, and so had to be removed. After his transfer to a nursing home for mental cases Professor Robertson thought it might be a case of general paralysis, and later he thought it might be early senility. Then it was found that the patient had pernicious anaemia, obscured by the mental symptoms. The delirious condition passed off quickly after proper nursing and treatment, but he was still disorientated; he did not know where he was, or realize the lapse of time. A marked symptom in him was amnesia; there was considerable want of the power of attention. Later, suspicion gave place to a mild elation, and he became dominating and dictatorial. When it was found that he had pernicious anaemia he was at once put upon liver treatment, and soon began to improve, both mentally and physically, and in six weeks he had left the nursing home quite recovered.

Dr. M. J. NOLAN referred to a similar case which he had seen; the mental symptoms in that case also were acute, and of the kind Professor Robertson mentioned. In a few months' time the liver treatment restored the patient to her duties.

Dr. W. F. MENZIES referred to a new refractometer designed by Dr. Malloy of Cheddleton Mental Hospital, which enabled a differential count to be arrived at from a smear in a very short time. Only four cases of pernicious anaemia associated with mental symptoms had been seen at Cheddleton in the last few years. Two of the patients died. In one of them the anaemia would never have been detected but for the routine examination being very thorough in every new admission, a course which he strongly advocated. The few cases he had seen had not enabled him to correlate definitely the mental with the physical states.

Sir HUBERT BOND referred to the liability of the mental symptoms putting the observer off the underlying physical state. This, incidentally, brought out the supreme importance of making a thorough clinical examination of the patient when admitted to the institution. It would be a matter of heart-searching if it were known how many patients did not have a proper blood examination. There should be a complete examination of patients at least once a year.

Dr. DOUGLAS MCRAE thought that in one of the cases related there was some mental improvement before the liver treatment was begun, and therefore more might have been claimed for the liver course than was its due. Patients showed periodic attacks of pernicious anaemia, which they recovered from, and the disease used to be cured by iron before the liver treatment was discovered.

Dr. J. R. LORD said Dr. Ford Robertson had found that pernicious anaemia was due to some elaborated septic process. With regard to the mental symptoms, he thought it likely that the anaemia depressed the liver function, which might cause the mental effects. On the other hand, the septic matter absorbed into the system might poison the brain and the liver too. Many realized that a vigorously functioning liver was an important factor in preserving a cheerful mentality. In ordinary life it was a common observation that liver sluggishness

was associated with irritability and bad temper. It might not be an unwise habit to take a morning "liver cocktail." Mental cases should not be considered as chronic until the expiration of at least three years, particularly those due to toxaemias and in elderly people whose colons were a perfect laboratory for the cultivation of all kinds of pathogenic organisms dangerous to the nervous system.

Dr. A. G. SHERA said the somatic side of mental disease now seemed full of hope, when compared with the outlook fifteen years ago. He considered, as a result of his experience, that mental symptoms in association with pernicious anaemia must be of rare occurrence. Eve's halometer showed up the megalocytosis of pernicious anaemia, and was valuable in borderline cases, which were a cause of much anxiety. But he would not like to separate out an unknown case with that instrument alone unless it gave a definite reading; it, however, allowed one to do the preliminary sorting, and that only occupied a few moments. In cases of pernicious anaemia he always pressed for a blood transfusion, as it shortened convalescence, and it should have an equally good effect on the mental symptoms in these cases. He had heard it argued that hydrochloric acid was essential to the amelioration of subacute combined degeneration. Streptococcus in the faeces was a characteristic of pernicious anaemia; he did not know whether it was a special strain, or whether it was a question of numerical increase in the streptococci present. If Dr. Phillips had provided another way of tackling mental disease he deserved every congratulation.

Dr. HAMILTON MARR mentioned the similarity of the mental and physical symptoms of these cases to those of myxoedema when untreated. The fresh liver treatment reminded him of the original treatment for myxoedema. If the liver principle could be given in a more assimilable form it would be an advantage.

The PRESIDENT thought it would be beneficial to try and ascertain why a patient with pernicious anaemia should have mental confusion and delusions of persecution. Certainly many patients with pernicious anaemia were lethargic.

THE VOLUNTARY MENTAL PATIENT

At a meeting of the London Association of the Medical Women's Federation, held on May 19th, with the president, Dr. LETITIA FAIRFIELD, in the chair, Dr. MARY BARKAS read a paper on the voluntary mental patient.

Dr. Barkas said that the main thing in the new Act with regard to voluntary patients was that provision for their treatment was not compulsory on the local authority. Even a statutory duty was often neglected by local authorities, so that there was not likely to be any great hurry to take up a permissive activity. Unless someone pushed the local authorities they would do nothing, and it was extremely important for all practitioners to look out for cases requiring such treatment and to see that the local authority made provision for them. Further, the Act now gave the local authority power to spend money on out-patient departments, preventive measures, research, and after-care. Again, it was the duty of practitioners to see that the money was spent. A good deal of the hopelessness often felt about mental patients was due to the fact that they were not treated until the most favourable period for treatment had passed. Those who had worked in institutions where voluntary boarders had been taken for some time had a more optimistic outlook. If the surgeon never saw a cancer case until three years after hope of successful treatment was over, and moreover had to live with those patients until they died, he would not feel he was getting the best chance. The general practitioner should be as ashamed of letting a mental case go beyond the curable stage as of letting a case of cancer become inoperable. How far the proportion of voluntary patients increased in public hospitals depended largely on the general practitioner, who needed a great deal more insight into the personality of mental patients. He was in a unique position for learning all about them, and for catching them in an early stage. Far too many practitioners told their patients to pull themselves together when they needed to be put to bed. "Make an effort, Mrs. Dombey," was the tragedy of many mental patients. All that voluntary patients had to do was to write to the medical superintendent and ask for admission; they could leave on giving three days' notice in writing, thus allowing time for communication with relatives and for making arrangements. The medical superintendent had to see that the patient understood these conditions; often a doctor would send up as "voluntary" a patient who was incapable of appreciating the situation. If the voluntary patient lost volition and remained without it for a month, he must be put on some other footing. In recent years the attitude of the Board of Control had altered very considerably; the Commissioners now wanted a patient to be on a voluntary basis if possible—provided only that he could understand his position. It was surprising to what extent really insane people would come as voluntary patients.

Discussing some types of voluntary patient, Dr. Barkas said that nearly every type of mental illness could be found among them—even acute mania and paranoia. Far more patients with delusions of persecution could be cured if they were taken in time; their delusions developed very slowly, and they did not generally reach a mental hospital for ten or twelve years after their first complaint. They came up for advice about headache or rheumatism, or some other ailment apparently irrelevant to their mental state, and the general practitioner should look out for them by inquiring of patients whether they thought there was any adverse influence affecting their health. The melancholic—the patient who got depressed and felt he was no good—was very suitable as a voluntary patient. Far too often these patients were treated vaguely by the general practitioner and urged to make an effort—until at last they committed suicide—whereas the first thing taught them in a mental hospital was to go to bed at once and stop making an effort as soon as this black cloud of dullness, absence of feeling, and insomnia came down on them. The difficulty was to select those melancholics who were best treated as voluntary patients. Some of them found it very difficult to make up their minds, and a decision to enter a mental hospital and stay there was beyond them. They constantly gave notice and withdrew it, and the ensuing worry prevented them from getting the needed rest. They were depressed, retarded, and full of guilt, and could usually be certified. When the decision was taken out of their hands they settled down and got better. It would have been an advantage, in Dr. Barkas's opinion, if the Act had provided that a voluntary patient, having once signed a request to enter a mental hospital, could be detained for a few months. Another type of possible voluntary patient was the neurotic. Many of these would be seen in the new out-patient departments, and in-patient provision for them was greatly needed. Whereas those in the psychotic group needed all the resources of the mental hospital, at any rate in reserve, the neurotics often needed no more than removal from home and an occasional talk, or a rest in the open air with massage, feeding-up, and, above all, a little understanding affection. Many people resented the idea that these patients should come under the Board of Control, but the smaller homes might be

very unsatisfactory if under no supervision. The neurotic was particularly liable to become the victim of the quack. If general hospitals made suitable provision for voluntary mental patients, neurotic patients would get the advantage of thorough physical investigation. The general hospitals were, however, short of beds, and their help would not go far. An out-patient department was essential for the neurotic and voluntary class of patient.

In reply to questions, Dr. Barkas said that the treatment of early paranoia in institutions depended on the employment of a sufficient staff. Many early cases of schizophrenia and other mental illness were much better treated outside a mental hospital, and some further provision was required for them. They needed both psychological and physical treatment—exercises and massage, for instance—and they tended, when once they got into hospital, to relapse into "just sitting." They might do well with out-patient treatment in their own homes. Some kind of social worker was essential; at least 50 per cent. of the treatment of the patient was treatment of the family.

In the ensuing discussion the PRESIDENT pointed out that the clause relating to temporary patients had been so whittled down in its course through Parliament that it was very difficult to interpret. It was extremely rare for any patient, not hopelessly insane, to remain without volition for a month. Mild and transient psychoses were far more common than was recognized. Lay people still tended to think of mental illness as a thing apart, and took any attempt to deal with it as an insult. Coroners were ready enough to attach blame to the medical profession for any slight error in physical treatment, but never mentioned the gross maltreatment of melancholia; they did not realize how easy it was to recognize early symptoms. One early manifestation sometimes encountered was extreme resistance to treatment of any kind: "I am unworthy of medical attention." The paranoiac, above all other people, could be moved by self-interest, and could be induced to enter a mental hospital if persuaded that it was to his advantage to do so. The public mind must be disabused of the idea that the early mental patient and the voluntary patient were necessarily curable. The voluntary provision was going to be of the utmost benefit and comfort to the chronic and relapsed patient. An out-patient department without in-patient beds was a useless thing. The out-patient department attached to the big general hospital and teaching school would, in her view, prove a delusion. Nor could the work depend on voluntary social service; it was astonishing that the Board of Control had not issued a warning against instituting any treatment without trained social workers.

Dr. MILDRED CREAK emphasized the number of cases of mild melancholia treated devotedly by the practitioner, up to the day of the suicide, as neurasthenia. The practitioner's attempts at distraction were comparable to taking a patient with a broken thigh folk-dancing. She questioned whether the anxiety of the legislator to safeguard personal liberty was really in the interest of the patient.

Dr. BARKAS, in reply, did not agree that an out-patient department without beds was useless. It might be valuable if it had attached to it some kind of occupational centre or hostel and a convalescent home. An apparently genuine neurotic might suddenly slip over into an acutely psychotic phase; it was therefore difficult to draw a hard-and-fast line between those who needed mental hospital treatment and those who could be safely treated outside. A good convalescent villa in a mental hospital was probably the best place to treat them. Every melancholic should be regarded as a potential suicide, and yet at the same time a certain amount of risk must be taken.

Reviews

THE MEDICAL ANNUAL, 1931

The Medical Annual[1] needs no introduction, and the present volume comes up to the high standard set by its predecessors. In the space at our disposal it is only possible to notice a few of the many items which together make up this conspectus of progress. Colonel L. W. Harrison, writing on the diagnosis of syphilis, mentions the important resolutions taken at the eighth International Congress of Dermatologists and Syphilologists in Copenhagen last year. The first was that at least two different sero-diagnostic methods should be used, one of which should be the Wassermann, and the other a reliable precipitation reaction. The second was that pathologists should agree on a uniform plan of reporting the results. It is well known that the sensitivity of the Wassermann reaction can be varied within wide limits by altering the nature of the antigen; too great an increase in sensitivity, however, leads to the occurrence of false positives. The advantage of the more recently elaborated precipitation reactions is that with most of them a considerably higher grade of sensitivity is attainable without the appearance of false positives. In the diagnosis of syphilis, therefore, in conjunction with the well-tried Wassermann reaction, one of the precipitation tests such as the Meinicke clearing or the Müller coagulation test should be employed. These tests are of particular value in following cases of treated syphilis, and in preventing the practitioner from discontinuing treatment as soon as the Wassermann becomes negative. Mr. J. P. Lockhart-Mummery draws attention to Cuthbert Dukes's findings on the mode of spread in carcinoma of the rectum. Starting in the mucous membrane, the growth spreads by direct extension on the surface and by infiltration of the rectal wall; it is not till the perirectal tissues have been penetrated that dissemination by the lymphatics occurs. Before the tumour has been excised and examined microscopically it is impossible to tell whether the perirectal tissues are invaded; in practice it is found that this invasion has occurred in three-quarters of all cases considered operable, and that in one-third of all operable cases there are actual metastases in the lymphatic glands. Treadgold's opinions on the method of estimating cardiac efficiency are referred to by Dr. A. G. Gibson. The physiological bradycardias, with a pulse even as low as 48 per minute, are generally evidence of good cardio-vascular stability; officers selected for the Royal Air Force rarely have a pulse rate above 72. It is considered important to ascertain the minimum blood pressure (diastolic); men with low minimum pressures show a greater tendency to fainting than others. A small pulse pressure, so long as the systolic pressure is not too high, is regarded favourably. In the treatment of rickets Dr. Reginald Miller remarks that there are now so many reliable methods at the disposal of the physician that it is a matter of difficulty in any one case to select the most suitable. One of the difficulties lies in the lack of standardization of such products as irradiated ergosterol, vigantol, and radiostol. For hospitals and welfare centres the most economical and efficient, provided a sample of proved antirachitic value is chosen, is still cod-liver oil. The interesting, but ill-named, subject of renal rickets is discussed by Sir William Wheeler, who illustrates his article by photographs and skiagrams of two cases under his care. The same author, dealing with the treatment

[1] *The Medical Annual*. Edited by F. Carey Coombs, M.D., F.R.C.P., and A. Rendle Short, M.D., B.S., B.Sc., F.R.C.S. Forty-ninth year. Bristol: J. Wright and Sons, Ltd.; London: Simpkin Marshall, Ltd. 1931. (Pp. xcix + 603; 143 figures, 70 plates. 20s. net.)

of burns, issues a warning against the application of tannic acid to the fingers at the tips; the resulting coagulum, he says, forms a very tight tourniquet, and the finger-tips may slough off. Professor Beckwith Whitehouse records the results of the experimental trial made by Professor Crew at Edinburgh of the Zondek-Aschheim test for pregnancy. The value of this test is still *sub judice*, but it appears that during the first few weeks of pregnancy it yields a correct answer in 95 to 98 per cent. of cases. False positives may be due to death of the ovum, incomplete abortion, hydatidiform mole, and chorion-epithelioma. A positive reaction persists for a few days after parturition and complete abortion, and may therefore have a medico-legal application. Mr. Stanford Cade contributes a critical article on the radium treatment of cancer. Public opinion as regards radium, he says, has passed from a state of exaggerated enthusiasm to that of cautious pessimism. Neither of these attitudes is justifiable. Radium holds a unique position in the treatment of malignant disease if the impossible is not expected. Early cancers in accessible situations give good results in a large number of cases, but radium *per se* remains a local remedy and is no weapon for the treatment of dissemination. Teletherapy, or treatment by the so-called "bomb" containing several grams of radium, has not yet achieved the results anticipated on theoretical grounds from massive irradiation. In the treatment of many tumours, such as those of the uterus, rectum, bladder, and buccal cavity, the most satisfactory method is the uniform irradiation of the cancer-bearing area by means of screened radium, so that gamma rays only are used, prolonged over periods of seven to ten days for intestinal, and two to three weeks for surface, treatment.

RADIOLOGY FOR STUDENTS

The elementary textbook of radiology by Dr. PETER KERLEY published in the Recent Advances Series, deals mainly with the correlation of radiological investigations with pathological findings. The title *Recent Advances in Radiology*[2] is just a little misleading, inasmuch as the author in ten chapters describes the radiological appearances, both normal and abnormal, of the various systems of the human body. Apparatus is omitted, and wisely so, for this can be better studied in the numerous catalogues of instrument makers. It is perhaps to be regretted that technique is also banned, for the many recent advances in technique are of interest to radiologists, though not to the general practitioner of medicine. The various chapters include injuries and diseases of bones and joints, the heart, the lungs, the alimentary canal, the biliary tract, the genito-urinary tract, and the uterus. The information given is accurate and well arranged; it is of necessity condensed, but at the end of each chapter a useful bibliography is added. The radiographs which illustrate the text are numerous and of uniformly good quality.

Recent advances in *x*-ray therapy are described in Chapter XI, the author stating that only the most important advances, and the trend of current opinion regarding them, are given. This chapter is not up to the standard of the rest of the book. It is scrappy and inaccurate, and the many dogmatic statements made are misleading, as no qualifying explanation is given. Thus in writing of *x*-ray dosage we find the following:

"Dosage in the earlier days was measured by means of pastilles which changed colour on exposure to *x* rays. The exposed pastille is compared with a standard in a calorimeter, and the dose delivered thus measured. There are three types of pastille in general use—the Sabouraud, the Holzknecht, and the Kienböck. The first two are remarkably accurate, but there are many fallacies in the last, owing to the numerous factors required for the development of the change in colour."

It was just because of the inaccuracy of the pastille method of estimating *x*-ray dosage that radiologists sought for, and obtained from the physicists, a more reliable method. Furthermore, the Kienböck method of estimating dosage is a photographic one, and does not involve the use of a pastille. Again, it is wrong to state that "there are many types of accurate dosimeters in which the dose is measured by a spectrometer or in terms of the ionization which takes place in an ionization chamber exposed to irradiation." A spectrometer is not used to measure the dose, but to determine the wave-length of the radiations. The definition of the international standard *r* is also wrong, and is obviously confused with the Solomon R. It is somewhat perplexing to the student to read on one page that—"the radiologist should not aim at cure by destruction of growth; he should rather aim at restricting the progress of growth, and at the same time raising the patient's resistance"—for on the next page he finds the statement that "550 to 700 *r* is lethal for most malignant cells. With well-chosen fields it is possible to deliver a lethal dose to a growth without causing more than a temporary erythema." The student will quite naturally ask how he is to reconcile these two statements.

In future editions the chapter on *x*-ray treatment should either be thoroughly revised or omitted, and we would suggest that the subject of recent advances in *x*-ray treatment, along with radium treatment, might form a separate volume in the Recent Advances Series. Apart from the chapter on *x*-ray treatment the book is good, and should prove an excellent elementary textbook on radio-diagnosis for students.

PRIMARY SYPHILIS IN THE FEMALE

Dr. ANWYL DAVIES's book, *Primary Syphilis in the Female*,[3] represents his London M.D. thesis, for which he was awarded the gold medal. How many medical practitioners have ever seen a primary chancre on the cervix uteri? Yet the author tells us that this is the commonest site on the female genitalia for a primary lesion—and who can contradict him? Dr. Davies has seized a golden opportunity to study an aspect of syphilis which is little known and which has been much neglected. Many observers have inquired why so little primary, as compared with secondary, syphilis is seen in the female, and here the question is answered; an interesting list of the various sites of primary genital chancres is given on page 10, and another on page 1 gives the occupations of the patients. Chancres in the various situations are considered separately and carefully classified and described; vaginal and extragenital chancres are shown to be much less common than is generally supposed. Differential diagnosis is discussed, and a description given of the various lesions which may simulate primary syphilis. Stress is very properly laid on the necessity for the use of the dark-ground microscope in every suspicious case; this, and this alone, will clinch the diagnosis in the earliest cases.

The coloured plates are beautifully reproduced, and convey a really faithful impression of the appearances of the lesions; some of the uncoloured photographs appear to have been over-developed. There is a good deal of repetition in the text, which might well be reduced by nearly a half. Much of the English is loose, such as

[2] *Recent Advances in Radiology*. By Peter Kerley, M.B., B.Ch., D.M.R.E. London: J. and A. Churchill. 1931. (Pp. viii + 324; 120 figures. 12s. 6d.)

[3] *Primary Syphilis in the Female*. By Thomas Anwyl Davies, M.D. Oxford Medical Publications. London: Milford, Oxford University Press. 1931. (Pp. viii + 111; 24 figures, 11 plates. 12s. 6d. net.)

" the cervix causes no pain " (p. 47) ; " this . . . converts a gonococcal colony into a pinkish-red colour " (p. 85) ; and there are a number of minor errors, such as labia for labium, infra for intra, inoculation for incubation, while on page 30, 27 chancres on the labia minora should read 47. The author is in error with regard to strepto-pneumococci ; they were described many years ago, certainly as far back as 1918. The statement on page 71 that tertiary syphilis of the cervix gives a negative Wassermann reaction in 65 per cent. of cases will be doubted by most syphilologists.

Dr. Davies's little book is the product of a wide experience, unremitting labour, and very careful observation ; it fills a gap in the literature of syphilis, and will be a revelation to many. There is a very complete bibliography.

A SYNOPSIS OF MEDICAL HISTORY

The study of the history of medicine is still somewhat of a luxury, for it needs some general education, leisure, and a desire to know how things came to be as they are. Hitherto the Dominions have been more concerned with the present and the future than with the past. Dr. BERNARD DAWSON'S little synopsis,[4] as the author modestly calls it, is a welcome sign of a change. It is the outcome of a series of lectures delivered to a class of junior medical students in the University of Adelaide, who were so interested that it is stated " all the students attended all the time." Their appetites being thus whetted it would have been well if Dr. Dawson had appended to his history a short list of books in which more detailed accounts of the different periods could be read, books not too abstruse, difficult to read, or expensive, but such as a student might buy for himself or obtain from the university library.

The author, who is a gynaecologist to the Adelaide Hospital, has succeeded in presenting a very complete history of medicine in the short space of 156 pages, beginning with Palaeolithic man and ending with Pasteur and Lister. The story is necessarily brief, but it is well told, and has been made interesting. For the most part it is accurate, and where all is good it may be somewhat ungracious to pick holes, though the holes are so minute that they can easily be darned in any future edition. For instance, on page 55, *rubor*, not *rigor*, is one of the four cardinal signs of inflammation ; on page 90 it is surely wrong to say that Saliceto, living in the thirteenth century, " recognized the venereal origin of syphilis " ; at page 99 St. Bartholomew's Hospital had not the rich founder there attributed to it. Rahere begged the ground on which it stands, and helped to build the original structure with his own hands. It is inaccurate to speak of different *volumes* of the *De Fabrica* of Vesalius, as is done on page 106, because it leads the beginner to think that the great work was issued in separate parts, whilst anyone who has consulted it knows, to his cost, the weight and solidity of the book. The fraternity of surgeons in London never received a charter, as is stated at page 117. The grant of 1492, which is there alluded to, was a grant of arms issued from the Heralds College, while " the writing of Compositions " of the following year was merely a friendly agreement between the Surgeons and the Barbers, which paved the way for their union in 1540.

The book is introduced with a welcome by Dr. H. Woollard, the Elder Professor of Anatomy and Histology in the University of Adelaide. It is illustrated with 31 figures, many of which are taken from the works of Dr. Charles Singer, and there is a satisfactory index.

[4] *The History of Medicine: A Short Synopsis.* By Bernard Dawson, M.D.Lond., F.R.C.S. London: H. K. Lewis and Co., Ltd., 1931. (Pp. xiv + 160 ; 31 figures. 7s. 6d. net.)

BILIARY FUNCTION

In their monograph on the Biliary Functions of the Liver[5] Drs. CHIRAY and THIÉBAUT undertake to consider the whole question of biliary function, and also the tests of hepatic function which may be of clinical application. It is an exasperating book, which might have been very useful if really complete, and it must be admitted that those who are interested in the subject will find Lepehne's monograph a safer guide. The book is ill-balanced, quite undue prominence being given to French work, and important foreign work being often ignored. For example, on page 9, when discussing the question of the origin of urobilin, the authors " are inclined to think " that the intestine is not the sole origin of urobilin, but they omit altogether any reference to the important work of Elman and McMaster (1925–26) in America. With regard to the bile acids, they conclude that " it is now permissible to consider the bile acids as products of oxidation of cholesterol by the liver," but few people will agree that the work of Grigaut in France, or of any other worker, is far enough advanced to justify this conclusion. On page 7, after recitation of the arguments, clinical and experimental, in favour of bile pigments being in large part formed outside of the liver and only excreted by the hepatic cells, Chiray and Thiébaut state as their view that " if the possibility of an extrahepatic formation of bile pigment seems actually demonstrated, its importance in normal conditions seems minimal compared with hepatic pigment formation." This question is still a difficult one, and the evidence provided in recent years is all in favour of the importance of extrahepatic pigment formation, while none has been offered in support of the view held by Chiray and Thiébaut. On the subject of cholesterol metabolism the authors are obviously much influenced by the past work of Grigaut. They point out one fact, too often forgotten by clinicians, that feeding a patient on four eggs a day for a whole week has practically no influence whatever on the cholesterol content of the blood or bile. The authors give a poor view of the functions of the gall-bladder and the modifications undergone by the bile in that organ. There is no reference whatever to the work of Peyton Rous, F. C. Mann, or others in this connexion. They do state that the bile is concentrated " three or four times " in the gall-bladder, but this estimation is now known (Rous) to be much too low, a concentration of ten times being nearer the mark. The remainder of the work calls for little comment, and it is unfortunate that a lack of completeness and balance should have spoiled a useful book.

NOTES ON BOOKS

Some two years ago Professor J. A. GUNN published a small volume[6] into which he had, with great care and discrimination, condensed the essential facts of pharmacology, with the purpose of giving students a short introduction to this subject. The work has evidently met a wide demand, for a second edition has already been required. The shortness of the interval between the two editions has rendered it unnecessary for the author to make many changes. The work has evidently been found of value by a large body of medical students, and thoroughly deserves its popularity, for it provides an excellent introduction to a difficult subject.

The scope and purpose of Dr. OXFORD'S book on the *Concise Anatomy of the Foot*[7] is sufficiently indicated in

[5] *Les Fonctions Hépato-Biliaires.* Par M. Chiray et F. Thiébaut. Paris: Masson et Cie. 1930. (Pp. 170. 24 fr.)

[6] *An Introduction to Pharmacology and Therapeutics.* By J. A. Gunn, M.D., D.Sc.Ed. Second edition. Oxford Medical Publications ; London: Milford, Oxford University Press. 1931. (Pp. viii + 223. 5s. net.)

[7] *A Concise Anatomy of the Foot.* By Arnold Whitaker Oxford, M.D. Cambridge: W. Heffer and Sons, Ltd. 1930. (Pp. 65 ; illustrated. 3s. 6d. net.)

the preface, in which he states that it has been compiled from larger anatomical works for the use of students of the school of chiropody attached to the London Foot Hospital. No doubt it will be found useful by those for whom it is intended. For members of the medical profession it presents in a handy and concise form a statement of what is known about the anatomy of the foot collected from various sources which will be convenient for reference and save the reader the trouble of looking up various sources.

The growing appreciation of the importance of a pure milk supply amply justifies the publication by Mr. A. G. HOUSE of his monograph on the *Bacteriological Control of Milk*,[8] in which a lucid exposition is given of the general and special technique of milk bacteriology. The care and maintenance of glassware and the preparation and standardization of media are fully dealt with. There is an informative note on milk sampling, which precedes a detailed account of the actual tests. The methods of recording results receive proper attention. The book is enhanced by its clear and adequate illustrations, and by the inclusion of an appendix on the furnishing of milk-testing laboratories. We commend it as a reliable guide to the practice of milk bacteriology.

The second edition has been published of the British Red Cross Society's *Cookery and Catering Manual*,[9] edited by Mr. C. H. SENN. The purpose of the manual is to assist members of the Voluntary Aid Detachments who undertake commissariat and kitchen duties, as well as those who act as cooks in hospitals and canteens. Special sections are devoted to invalid and camp cooking, hospital rationing, and the dietetic values of foods.

The ninth edition of Dr. J. COMBY'S Medical Consultations for the Diseases of Children[10] contains details for the treatment of over four hundred maladies. Since the book was first published in 1909 the number of treatments thus described has multiplied fourfold, together with an increase in the popularity and usefulness of the book. Dr. Comby's plan is to give first, in detail, the exact treatment of a disorder, and this is followed by a brief summary of the etiological, diagnostic, and prognostic factors of the disease. The list of subjects is remarkably complete, including many tropical disorders, and the advice given is for the most part thoroughly practical.

Aids to Dispensing,[11] by Staff Sergeant G. ASHTON, is a practical guide which has been adopted at the R.A.M.C. School of Dispensing, Crookham, for the use of students. In compiling it the author has had the help and encouragement of many officers of the Corps. It is divided into four sections, devoted respectively to materia medica, official preparations of the *British Pharmacopoeia*, practical dispensing and pharmacy, and poisons.

[8] *Bacteriological Control of Milk*. By A. G. House. With a foreword by Professor R. Stenhouse Williams, M.B., D.Sc., D.P.H., etc. London: Cambridge University Press. 1931. (Pp. 59; 29 figures. 3s. 6d.)

[9] *British Red Cross Society: Cookery and Catering Manual*. No. 5. Edited by Ch. Herman Senn, O.B.E., F.R.H.S. Second edition. London: Cassell and Co., Ltd. 1930. (Pp. viii + 232. 2s. net.)

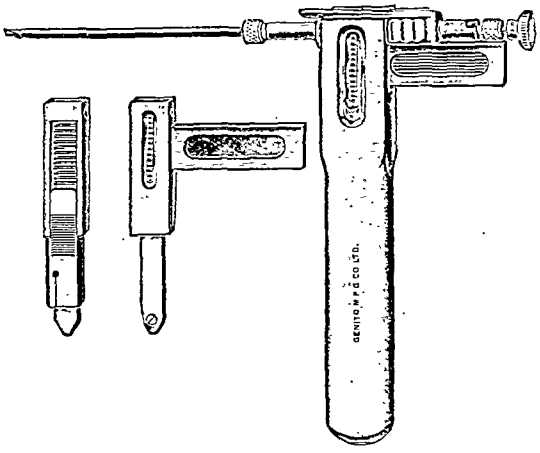
PREPARATIONS AND APPLIANCES

RADON SEED PISTOL

Dr. ROY WARD (Medical Director, Radium Institute, London) writes:

The accompanying illustration shows a radon seed pistol, which has been designed for the Radium Institute by the Genito-Urinary Manufacturing Company, Devonshire Street, W.1.

The handle is made of a hollow aluminium casting, the lower portion of which contains a strong circular spiral spring. The upper third is rectangular in cross section, and forms a chamber which holds the magazine. A slot is cut through the wall on one side, exposing the seeds to view. A sliding lid closes the chamber and keeps the magazine in position. The posterior portion of the lid, which acts as a guide for the stylet, is fitted with a detachable nut to prevent the complete withdrawal of the stylet when the instrument is in use. In alignment with this portion of the lid, and fixed to the handle, is a fitting designed to hold the hollow needles, which are graduated in centimetres. These are clamped to the handle by means of a detachable nut, and may vary in length from 5 to 25 cm. The magazines consist of rectangular metal containers of such dimensions as to fit exactly into the corresponding chamber of the pistol handle. The interior is hollowed out to hold twelve seeds. The upper end is closed, except for a transverse hole, through which the stylet passes. There are two kinds of magazine—one for "permanent"



and one for "removable" seeds. In the magazine for "removable" seeds, the narrow side has a fine slot just wide enough to allow the threads to pass over the thread carrier. This is a thin flat piece of metal attached to the magazine, with a notch at its extreme end, round which the threads are gathered and held in position by a spring cap. A plunger fitted into the seed chamber completes the mechanism. When the magazine is loaded the plunger projects by a distance equal to twelve times the diameter of the twelve seeds, and compresses the spring in the pistol handle by that amount. As one seed after another is pushed out of the magazine, the plunger, forced up by the spring, lifts the seeds into position until all are expelled by the successive to-and-fro action of the stylet.

The instrument has been designed not only for the rapid introduction of radon seeds, but to facilitate their handling and to provide an introducer which may be used for their insertion into any region of the body. For instance, short needles are employed when implanting seeds into the skin, a curved needle for the nasopharynx, and a long needle for the rectum. The handling of these minute radon tubes has always presented difficulties, especially in the case of those fitted with threads. The magazines are loaded in the physics laboratory, thus facilitating their manipulation and reducing exposure risk to a minimum.

ANTIPNEUMOCOCCIC SERUM

Antipneumococcic serum (Felton), Types I and II, refined and concentrated, is now issued by Messrs. Parke, Davis and Company. This product is the result of prolonged researches. Felton devised the method for standardizing the activity of this serum, and also for removing the extraneous proteins. The dosage advised is from 40,000 to 100,000 units in the first twenty-four hours. Early treatment is essential, and Type I infections respond more quickly than do Type II. A dose of 10,000 to 20,000 units is recommended on the second day. Serum reactions can be controlled by giving desensitizing doses and by adrenaline. This serum is attracting general interest at present, because very favourable results have already been reported in the treatment of Type I lobar pneumonia.

THE LÜBECK CATASTROPHE

A GENERAL REVIEW

In the early part of last year there occurred at Lübeck in Germany one of those happily infrequent disasters which have from time to time accompanied the use of prophylactic vaccination. The vaccine used on this occasion was prepared from the B.C.G. strain of tubercle bacillus, which, as is well known, has, as the result of subculture for several years on a glycerin-bile-potato medium, become almost entirely avirulent to man and animals. During a period of two months, stretching from February 24th to April 25th, 1930, this vaccine was administered to 249 newly born infants. Of these many developed acute tuberculosis during the next few weeks and died; others developed subacute lesions, while a considerable proportion remained perfectly well. The total death roll up to January 29th of this year was seventy-five. Inquiry into this catastrophe was rapidly set on foot, and papers have been published, particularly by Professor Ludwig Lange[1 2] of the Reich Health Office, and Professor Bruno Lange[3 4] of the Robert Koch Institute in Berlin, dealing with the results of the investigation. Pending the issue of an official report containing all the findings, it is perhaps worth while summarizing the knowledge which has so far been gained of this most regrettable incident.

PREPARATION AND DISTRIBUTION OF THE VACCINE

On July 27th, 1929, a strain of B.C.G. was sent from the Pasteur Institute in Paris to Dr. Altstaedt of Lübeck, who handed it to Professor Deycke of the General Hospital. Some time after its arrival the culture was inoculated into animals, and apparently proved to be avirulent. According to Calmette[5] the same strain was also sent to Mexico and to Riga, and the following subculture was used for the preparation at the Pasteur Institute of a vaccine which was administered to 3,016 infants without any detrimental result. There is therefore very little doubt that the culture originally sent from Paris was avirulent.

It has been the practice of Calmette and Guérin to keep their B.C.G. strain in the laboratory on a glycerin-bile-potato medium, and for the preparation of vaccine to grow it in Sauton's liquid medium. Deycke, however, after using the potato medium for a short time, subcultured his strain on egg medium, with or without the addition of haematin, and used these solid cultures for the subsequent preparation of his vaccine.

Before the receipt of the B.C.G. strain, Deycke was in possession of a number of cultures of tubercle bacilli, but owing to an accidental rise in the temperature of the incubator in which they were kept these were all killed.

For a time, therefore, the B.C.G. strain was the only culture of tubercle bacilli in the laboratory. In September, 1929, however, a strain, reputed to be of human type, was obtained from Kiel. This strain was isolated in 1927 from a child with hip-joint disease at the Charité Hospital, Berlin, and was handed over in 1928 to the Robert Koch Institute, where it was given the label H29; in April, 1929, a subculture was forwarded to the Hygienic Institute at Kiel. In Deycke's laboratory the B.C.G. strain was kept in an incubator in a small room and was subcultured on a solid medium; the Kiel strain was kept in an incubator in a large room, and was subcultured only on a fluid medium. The actual preparation of the vaccine was entrusted to a woman assistant, who had been with Deycke for seventeen years.

On December 9th, 1929, a preliminary inoculation was made of one child, which had been removed at birth from a mother suffering from open tuberculosis. A second child was vaccinated on December 30th, 1929. The first child developed cervical lymphadenitis, which was attributed to congenital infection, and inoculation of an excised gland into a guinea-pig gave rise to general tuberculosis. The second child remained well, but developed a positive tuberculin reaction. One further preliminary inoculation was made on February 10th; this child subsequently developed mild symptoms of tuberculosis. The main series of vaccinations was commenced on February 24th, 1930, and between this date and April 25th 249 infants, about 50 per cent. of those born in Lübeck during this time, were inoculated, the usual three doses being given in the first ten days of life. Though suspicions were early aroused by the clinical condition of the vaccinated infants, nothing definite occurred till April 17th, when a child, vaccinated thirty-three days previously, died; unfortunately, permission for a necropsy was forbidden. On April 20th a second child died, and was found post mortem to have generalized tuberculosis; since the lesions were most marked in the lungs, it was concluded that the child had been infected by the respiratory tract from its mother, who was suffering from tuberculosis, though not of the open type. It was not till the third and fourth children died, on April 25th and 26th respectively, that the pathogenic nature of the vaccine was fully realized, and further distribution was stopped. At this juncture Professor Deycke, in order to avoid any possible error, destroyed all the remaining vaccine in the laboratory, together with the existing subcultures of the B.C.G. strain. This unfortunate step, which was clearly open to more than one interpretation, added greatly to the difficulties of the subsequent investigation.

TIME DISTRIBUTION OF THE DEATHS

According to Professor Bruno Lange,[4] on October 18th, 1930, the figures were as follows. Of 252 inoculated children 67 had died from tuberculosis; 5 children had died from other causes, but in 2 of them tuberculosis was found; 21 children still living were severely ill, and 87 slightly ill; 72 children were apparently well. According to Professor Calmette,[6] in an article published on January 24th, 1931, the death roll had mounted to 75. One of the remarkable features of the deaths was their peculiar time distribution in relation to the issue of the vaccine. They may be divided into the following periods (see table).

Morbidity and Mortality According to Position on October 18th, 1930

Period	No. of Vaccinated Infants	Died from Other Causes	Remained Well	Slightly Ill	Severely Ill	No. Dying	Percentage Dying
9/12/29 to 10/2/30	3	0	1	2	0	0	0
24/2/30 to 27/3/30	129	1	10	40	17	61	47
28/3/30 to 7/4/30	32	2	20	9	1	0	0
8/4/30 to 10/4/30	21	0	6	10	1	4	19
11/4/30 to 25/4/30	67	2	35	26	2	2	3
Total ...	252	5	72	87	21	67	27

It will be noted that the highest mortality followed the vaccine distributed in the last week of February and the first four weeks of March; subsequently came a period of ten days in which the vaccine was comparatively innocuous; then there was a short period of three days during which it again proved pathogenic; and finally, a period lasting for a fortnight characterized by a marked fall in its virulence. In the cases that proved fatal the time elapsing between administration of the vaccine and

death varied considerably ; figures for the complete series of cases have not been published, but the average period seems to have been about twelve weeks, with a minimum of thirty-three days. As regards sex, the male infants suffered more severely than the female ; thus, of 139 boys vaccinated 38, or 27 per cent., died ; of 110 girls vaccinated only 17, or 15 per cent., died.

CLINICAL AND POST-MORTEM FINDINGS

According to Dr. M. Klotz,[7] director of the Children's Hospital at Lübeck, the early symptoms observed were failure to thrive in spite of breast-feeding, mild febrile attacks, vesicular eruptions, and swelling of the cervical glands. Later, in the more severe cases, the cervical glands enlarged to the size of hen's eggs, and caused interference with respiration and swallowing ; and there developed an extreme degree of anaemia, high intermittent fever, prolonged vomiting, profuse diarrhoea, and very severe meteorism, generally localized to one or two parts of the abdomen, and found at necropsy to result from innumerable strictures of the gut with consequent strangulation through adhesions and enlarged glands. Tubercle bacilli were found without difficulty in the vomit, sputum, and stools.

Post mortem the picture was uniformly that of the type of tuberculosis commonly found after alimentary infection. Besides involvement of the intestine, with numerous ulcers and strictures, and enlargement of the mesenteric glands, the lungs were infiltrated, often one or more lobes being affected, and the infiltrated areas looking like Perlsucht nodules. The glandular enlargement was enormous. Purulent discharge sometimes flowed from the nose, and ulcerating skin rashes were occasionally found. Pleural and peritoneal exudates were not uncommon. But, strangely enough, no meningitis or cerebral tuberculosis was seen. The condition of the bronchial glands is not mentioned.

EXAMINATION OF THE AVAILABLE CULTURES

Considerable difficulty was experienced in obtaining suitable cultures for examination, since the B.C.G. subcultures and the vaccine in Deycke's laboratory had been destroyed ; the following material was ultimately collected, and examined by Professor Bruno Lange.

1. Organs from four infants who had died after vaccination, together with a culture obtained by Deycke from a cervical gland of a sick infant. The organs, when inoculated into guinea-pigs, gave rise to tuberculosis of a type considerably less severe than that normally following the injection of a fully virulent mammalian strain. Three strains recovered from the organs gave rise to a mild, fairly generalized tuberculosis, with a tendency to retrogression in animals injected with small doses. Subcutaneous inoculation of rabbits with organ suspensions led to nothing more than a local lesion. Intravenous inoculation with a pure culture (dose not stated) led in one rabbit killed eight weeks later to moderately extensive lesions in the lungs, and to a few submiliary nodules in the spleen, and in another rabbit killed five months later to several caseous areas in the lungs, up to a bean in size, to numerous miliary caseous tubercles in the liver, and to one large tubercle in the cortex of the right kidney. Culturally the three strains from the organs gave a moist, smeary growth on serum egg medium, typical neither of the human nor of the bovine type, though more closely resembling the former. Lange is unable to come to any definite conclusion as to the type of tubercle bacillus in these cultures. The strain recovered by Deycke behaved similarly to the three organ strains.

2. A culture isolated by Deycke on April 17th, 1930, from a guinea-pig injected on March 6th with a culture of B.C.G. ; this is referred to as the B.C.G. guinea-pig passage strain. According to Deycke four guinea-pigs were inoculated with the B.C.G. strain, and four more with material from a cervical gland of a vaccinated infant. Both sets of animals were injected six weeks later with 0.5 c.cm. of tuberculin, with the result that all of them died. At post-mortem, however, while three of the guinea-pigs inoculated with the glandular material showed generalized tuberculosis, the four guinea-pigs inoculated with B.C.G. showed lesions confined to the great omentum. Examination of the guinea-pig passage strain by Lange proved that it was capable of producing fairly severe progressive tuberculosis in guinea-pigs, while proving avirulent to rabbits. Culturally it resembled the human type.

3. A culture found in the middle of May, 1930, in the laboratory of the Lübeck Hospital, and labelled " B.C.G. 14.3.30." The sister cultures had probably been used about the end of March or beginning of April for the preparation of vaccine. Two subcultures of this strain, which is referred to as B.C.G.143, were also found. On subcutaneous injection of guinea-pigs it gave rise to no more than a local lesion, with some involvement of the regional glands, and even large doses failed to set up progressive generalized tuberculosis. To rabbits injected subcutaneously with 10 mg. and intravenously with 0.01 mg., it was completely avirulent. Culturally, it behaved more or less like a bovine strain, though growing freely on glycerin agar and glycerin broth. Lange concludes that it was probably a B.C.G. strain, though rather more virulent than the B.C.G. strain in the Robert Koch Institute, which was tested for comparison. It is probable, he considers, that not all strains of B.C.G. given out by the Pasteur Institute have been of the same degree of avirulence.

4. The culture received by Deycke from Kiel in September, 1929. This strain, which had come from the Robert Koch Institute in Berlin and was reputed to be of human type, proved to be of attenuated virulence for guinea-pigs, and to be almost avirulent for rabbits. Culturally it was of human type, but Lange considers the pathogenicity experiments to be too ambiguous to enable a definite diagnosis of type to be made.

5. A culture of the same strain as No. 4, but kept in the Robert Koch Institute since 1928. This strain, which was labelled H29, had been isolated in 1927 from a child with hip-joint disease in the children's clinic of the Charité Hospital, Berlin, and had been handed over to the Robert Koch Institute in 1928. In April, 1929, it was sent to Kiel, and in September, 1929, a subculture was forwarded from Kiel to Lübeck. Professor Opitz, who originally isolated it, suspected it of being bovine in type. When tested in 1930, it proved to be of definitely attenuated virulence for guinea-pigs. Rabbit inoculations gave inconstant results ; some rabbits developed tubercles in the lungs, one showed no disease, and one died with numerous tubercles in the lungs, kidneys, and liver. Culturally it resembled the human type, but Lange does not decide whether it was of human or bovine type.

Other material was collected and examined by Professor Ludwig Lange at the Reich Health Office. A full report of his investigations has not yet been published, but according to information given to the press by the Ministry of the Interior in July, 1930,[8] the following material was examined.

1. A strain of B.C.G., which since its arrival at Lübeck from Paris had been kept on a fluid medium. This strain, which was not used for vaccine preparation, proved avirulent to guinea-pigs, behaving, therefore, like a typical B.C.G. strain.

2. Two cultures of B.C.G., one corresponding to a batch of vaccine that gave rise to little disease and no deaths ; and one put up during the second half of April, and never used for vaccine preparation. Both of these cultures proved avirulent to animals.

3. The remains of four batches of vaccine, apparently in the possession of midwives. Two of these batches

corresponded to a high morbidity and mortality. They are still under examination, but according to Neufeld[10] both virulent and avirulent bacilli were recovered.

4. A culture that had been isolated by Deycke from a guinea-pig inoculated on March 6th, 1930, with a presumably pure culture of B.C.G. on a solid medium. This culture, which had been put up in Lübeck on April 17th, was found in the Reich Health Office laboratories to be highly virulent for guinea-pigs and only slightly virulent for rabbits, behaving, therefore, like a human type.

5. A guinea-pig inoculated by Deycke on April 17th with another, presumably pure, culture of the B.C.G. strain, was taken to Berlin, and when killed 109 days after inoculation was found to have extensive tuberculosis.

DISCUSSION

Numerous hypotheses have been put forward by different workers to explain the virulence of the Lübeck vaccine, and it has even been suggested that, in order to increase the immunizing effect of the B.C.G. strain, small doses of virulent tubercle bacilli were intentionally added to the vaccine (Ascoli[9]). The real point at issue is whether another strain of tubercle bacillus became mixed with, or substituted for, the B.C.G. strain in the preparation of the vaccine, or whether the B.C.G. strain actually underwent a spontaneous increase in virulence.

In considering the first possibility it is necessary to remember that in the laboratory at Lübeck, throughout the time at which the vaccine was prepared, there was only one other strain of tubercle bacillus ; that this strain, which was either of attenuated human or attenuated bovine type, was kept in an incubator in a different room ; and that while the strain of B.C.G. used for vaccine preparation was subcultured on a solid medium, this strain was subcultured on a fluid medium. Confusion of the two cultures in these circumstances does not, on *a priori* grounds, seem to be very probable. Professor Bruno Lange, who upholds this hypothesis strongly, appears to be influenced in his judgement chiefly by a strong prejudice against believing in the possibility of a spontaneous reversion to the virulent form of the B.C.G. strain, and partly by the recovery from fatal cases of cultures more or less resembling in virulence the strain of reputed human type received by Deycke from Kiel.

In this connexion it may be remarked that at the outset of the inquiry great hope was entertained of the results of typing the bacilli recovered from the vaccinated cases. The B.C.G. strain was of bovine origin ; the Kiel strain was supposed to be of human type. Clearly, if one or other type was found in the organs of infants who had died after vaccination, it would be reasonable to assume that it was the corresponding type which had been present in the vaccine. Unfortunately, however, this hope was doomed to failure. In the first place it was forgotten that the bacteriological method of typing tubercle bacilli was capable of giving clear-cut results only with strains more or less freshly isolated from the animal body, which had not been accustomed to growth for long periods of time on artificial media. It so happened, however, that both the B.C.G. strain and the Kiel strain were old laboratory cultures, and could not, therefore, be expected, after a single passage through the body, to behave like typical strains. In the second place, it is not by any means certain that the Kiel strain was of the human type. Professor Opitz suspected it of being of bovine type, and Professor Bruno Lange was unable to determine whether it was of human or bovine type. The argument has been put forward that, because this strain was avirulent to rabbits, it must necessarily have been of human type ; but since its virulence for guinea-pigs was attenuated, it is impossible to lay any stress on this point. Many cultures of bovine type, which are becoming attenuated, behave exactly in this manner, losing their virulence for the rabbit before that for the guinea-pig. It is therefore clear that no definite conclusion can be reached whether the strains isolated from the vaccinated infants were identical with the Kiel strain. Professor Bruno Lange regards this as probable, but he is admittedly unable to prove it conclusively. He is supported, however, in his general inference by Professor Neufeld,[10] who believes that the Kiel strain was incorporated in the vaccine.

The other hypothesis, involving the spontaneous reversion of the B.C.G. strain to the virulent state, has been put forward by numerous workers both in Germany and abroad, and is sponsored by no less an authority than Professor E. Friedberger.[11] It is unnecessary to recapitulate here the experimental evidence that has been obtained in various countries in favour of this possibility. Experiments by absolutely independent workers have shown that the virulence of the B.C.G. strain is not fixed, but that under certain cultural conditions, either *in vitro* or *in vivo*, it may be rendered more or less completely virulent to animals.

To assert, as Calmette does, that in all these experiments the culture has become contaminated with another strain of tubercle bacillus is to offer an excuse that becomes increasingly tenuous with each additional piece of evidence brought forward. The fact that when kept on a glycerin-bile-potato medium, and when given to newborn infants, it proves to be avirulent, does not in any way disprove the possibility of its becoming virulent when exposed to other conditions. There is rapidly growing up a mass of careful observations, made on bacteria of different species, which indicate that the cultural appearances, the antigenic structure, and the virulence of an organism may be altered by a number of different environmental factors, and no one who was not completely ignorant of recent work in the field of bacterial variation would dare to maintain that a given culture was of fixed and immutable virulence.

In favour of the second hypothesis it has been pointed out by Friedberger and others that the Lübeck strain of B.C.G. was subcultured, not on glycerin-bile-potato, but on an egg medium ; and these workers have suggested that growth on this medium may have led to an increase in its virulence. So far no experimental evidence has been adduced to support this suggestion, and the few experiments made by Saenz[12] to test it have proved negative. The results obtained by examination of the various cultures at Lübeck can equally well be explained by assuming that the B.C.G. strain had acquired a certain degree of virulence as that it had become mixed with the moderately virulent Kiel strain.

Frankly it is impossible, on the basis of these results, to decide which of the two hypotheses is correct. In the absence of definite evidence it is wise, though unsatisfying, to maintain an open mind as to the real cause of the Lübeck catastrophe. The moral, however, is plain. The preparation of vaccines for large-scale distribution should be undertaken only under the most rigidly controlled conditions in laboratories set aside for this and for no other purpose.

SATURDAY, JUNE 6th, 1931

HAEMOLYTIC JAUNDICE

The interesting features of this remarkable familial and congenital disease have been prominently brought before our readers in the Hume Lectures delivered at Newcastle-upon-Tyne by the President of the Royal College of Physicians. Lord Dawson's special interest in this group of cases is well known to his fellow physicians in this country, and he has already described to a limited audience, at meetings of the Association of Physicians, some portions of his work. In the present lectures he collects the results of his observations on forty cases, and is thus able to emphasize most of the well-known clinical and pathological features presented, and to give us a very complete picture of the disease and its proper method of investigation and treatment. In the preamble to his first lecture (printed in our last issue) he runs over the facts that have been discovered in the past decade concerning bile-pigment metabolism, without a full knowledge of which the study of haemolytic jaundice is impossible. He seems to adopt as most suitable the recent classification of icterus by Rich into " retention " and " regurgitation " jaundice —a grouping largely founded on the results of the van den Bergh test. But in the opinion of many interested in the subject a classification on so narrow a basis is not to be preferred to other and simpler classifications of jaundice.

The two most characteristic and well-known phenomena of the disease are its familial incidence and the undue fragility of the red blood corpuscles to varying concentrations of sodium chloride in solution, when compared with the red cells of normal individuals. This undue fragility of the red corpuscles, first pointed out by Chauffard of Paris in 1907, is a remarkable phenomenon. Lord Dawson is fortunate in being able to reproduce records of his cases by the graphic method elaborated by E. ff. Creed of King's College Hospital. This method, we are glad to see from the bibliography, is " about to be published." It is a technique already well known by word of mouth to a number of clinical pathologists in London, and a full publication by its author has been long awaited. It is bound to find its way at once, as the accepted standard method, into textbooks of clinical pathology. Lord Dawson rightly points out that undue fragility of red corpuscles is not observed in *all* cases of the disease, though it is found in by far the majority. This is a curious and interesting point, perhaps too apt to be lost sight of ; but all it probably means is that haemolysis of red cells by solutions of sodium chloride is an artificial and arbitrary test of some abnormality of the red corpuscles, the exact nature of which is unknown to us. In cases treated by splenectomy the undue fragility to the saline test seldom disappears altogether ; it may be distinctly modified in the right direction in some cases, but is often quite unchanged. That it may persist unaltered for more than forty years, in a patient cured of the disease by splenectomy, is well shown by the famous case operated on by Sir Spencer Wells, to which we refer again later.

The family groups of cases recorded by Lord Dawson are especially interesting, since in their graphic description he is able to bring out the principal points in the symptomatology and complications of the disease. This is an important section of these lectures for the physician who has to advise on the treatment of the recognized disease. He must know well all the possible complications and their incidence, so that he may put the case for splenectomy fairly and squarely before the patient or the parents. These complications are dealt with in the first part of Lord Dawson's second lecture, printed in our opening pages to-day. In his series of forty cases, twelve fatalities have occurred, only one of these being due to the surgical risk of splenectomy. Eight of the patients died from acute haemolytic anaemia, two from cholangitis complicated by anaemia, and two from intercurrent disease. The eight deaths due to what are sometimes called " acute blood crises " are noteworthy in this series because of their frequency. It must be remembered, however, that this haemolytic disease shows marked periodicity in its intensity. It waxes and wanes, and a period of acute haemolysis, with the blood picture associated with a " crisis," with rapidly increasing jaundice and acute and great splenic enlargement, is often followed by a long period in which all these signs are much modified. The spleen shrinks with great rapidity, the jaundice may disappear, and the anaemia diminishes. It has perhaps not been sufficiently realized in the past how important and how dangerous for life these periods of active haemolysis may be. That biliary complications are apt to ensue is of course due to the greatly increased bile-pigment production during the active periods of haemolysis. Two fatal cases of cholangitis and anaemia are referred to, but the occurrence of pigment (bilirubin) gall-stones and even of acute biliary colic is more commonly described in the literature than the lecturer's personal experience might indicate. All of these complications offer the strongest arguments in favour of splenectomy at an early age, and, if possible, at a time when the patient is relatively well, since they never recur after the spleen has been removed.

Haemolytic jaundice, as seen in elderly people who have suffered from the disease since childhood, presents some particular features of interest, which are very well brought out in these lectures by the histories of two sisters aged 53 and 55. One sister died at 53 from acute anaemia, showing that survival to middle age is no bar to a fatal haemolysis. The other, aged 55, has led, and still leads, an active life, with a red blood cell count now below 3 millions and a haemoglobin percentage of 32. This latter case, indeed, shows how the human body may adapt itself by long practice

to what would ordinarily be considered very adverse conditions. On the face of it, however, the risk of splenectomy in early life must nowadays be considered small in comparison with the continued risks these two sisters have run throughout their lives. One very striking historical case is referred to in detail by Lord Dawson—the patient "Fordal," operated upon in 1887, when aged 27, by Spencer Wells, who successfully removed a spleen weighing over eleven pounds. This patient is still alive, and well for her age, forty years after the operation; it is interesting that her red blood corpuscles are still unduly fragile in the test saline solutions. Her only son, moreover, developed the disease, and has been operated on twice—first for removal of pigment gall-stones, and later for splenectomy, with complete cure resulting.

In his second lecture Lord Dawson gives an account of the morbid anatomy and histology of two fatal cases. Finally, in this lecture he considers the old but none the less interesting question whether there is an acquired form of haemolytic icterus in addition to the common congenital variety. Most workers, after weighing all the recent evidence, will agree fully with Lord Dawson that the more carefully the cases are investigated, both individually and from the family standpoint, the more does the probability of a genuine "acquired" form sink into the background. All our readers will agree that the lecturer is to be congratulated on the important observations he has made on this long series of cases, and we must not omit to mention the excellence of the coloured drawings with which his second lecture is illustrated. The clinical features of haemolytic jaundice are now well known and amply documented. Large monographs (for example, Meulengracht's) have been written upon it from every clinical and pathological angle. The main puzzle remains, the first and so far the only clue to which was given by Chauffard in 1907, when he pointed out that the red blood corpuscles in this disease begin to lake in higher concentrations of salt solution than do normal healthy red corpuscles. Why the increased haemolysis, and why its curious periodicity? These two questions remain unanswered.

THE PREVENTION OF SMALL-POX

We print elsewhere (at page 995) a short précis of the memorandum on small-pox prevention which has just been issued by the Ministry of Health. We hope that this summary will stimulate our readers to peruse the memorandum itself, which is, in our opinion, a masterly document, an example of the way in which a State paper dealing with a very difficult and highly controversial subject should be composed.

The literature of the vaccination controversy is interesting, if not particularly agreeable, reading, and questions once so keenly debated respecting the scientific value of Jenner's own work, and the influence of vaccination upon the epidemiology of small-pox in the first half of the nineteenth century, are only of historical interest. Hardly any men of science now doubt that vaccination is, as the memorandum asserts, an efficient if not infallible prophylactic against taking small-pox if exposed to risk, or against dying from small-pox if attacked. But few epidemiologists believe that the vicissitudes of epidemic small-pox in the last 130 years are mere reflections of variations in the communal or individual resort to vaccination. Further, the experience of the last quarter of a century has done something to shake the conviction that a community such as ours, wherein the proportion of the whole population at any given time who have been recently vaccinated is far short of 25 per cent., is likely to be ravaged by epidemics of malignant small-pox. Most of us might indeed hold that much suffering and some deaths would have been avoided if our people had been as docile as the Germans of the generation of the years immediately prior to the war and had submitted to a system of really compulsory vaccination and revaccination; but it would be foolish to shut one's eyes to the fact that only some revolution of public feeling, leading to a dictatorship like that in Italy, could produce an effective compulsory system of vaccination and revaccination.

We have, indeed, to choose between a sham system of compulsion and an appeal to reason. The memorandum sets out the alternatives judicially. Perhaps we might put the case made for an appeal to reason in this way. Every year the public health services and the medical profession as a whole are persuading the general public to adopt certain habits and to abandon other habits by convincing them that such changes are beneficial. Much is no doubt effected by mere authority. All men and women, even the English, however much they may abuse officials and doctors in the mass, are inclined to do what the individual official or the individual doctor recommends without being very curious as to the reasons for his advice. Something, however, must be allowed to reasonable conviction and hardly anything to legal sanctions. We have little doubt that if the legal sanctions were abolished and small-pox prophylaxis were treated from the educational point of view, as child welfare is now treated, the vaccinal state of the community would not be worse than it is, but better. We do not mean that the organization of an educational campaign will be easy; it will be a difficult undertaking. The cause of vaccination has been far more damaged by the rashness of its advocates than by the skill of its enemies. The tone and temper of this memorandum should be contrasted with that of Simon, issued by the predecessor of the Ministry of Health more than sixty years ago. *This* memorandum, and not the dogmatic rhetoric of our predecessors, should be a model for those who have the duty of educating the public.

We have left little space for reference to the purely scientific aspects of the memorandum. One, however, may be noticed. Evidence is submitted that variola minor, after it has gained a foothold in a community,

increases more or less steadily for five to six years and thereafter declines. It is an interesting question to consider whether the decline is due to a critical level of herd immunity having been reached by means of subclinical infections. There is experimental evidence that in virus diseases the process of immunization is different from that obtaining in at least some bacterial infections; it seems probable that in variola minor natural immunization may be very effective, and the future course of events in districts which have been heavily infected will be worthy of consideration. Both from the point of view of the administrator and from that of the pure epidemiologist this memorandum is a valuable document, which reflects great credit upon its author or authors.

THE EASTBOURNE PROGRAMME

Arrangements are now well advanced for the Annual Meeting of the British Medical Association, to be held at Eastbourne towards the close of next month, under the presidency of Dr. W. G. Willoughby. The occasion is noteworthy for two reasons. In the ninety-nine years since its foundation the Association has never before met within sight of Beachy Head; nor has it had as its President a medical officer of health. The first is perhaps a mere accident of geography; but the second marks a stage in the reintegration of medicine which may signify a good deal to the student of professional history in these islands.

Before the Annual Meeting proper opens, with full ceremony, on the afternoon of Tuesday, July 21st, the Representative Body will have sat in session for four days and worked through a long agenda of medico-political and administrative business based on the Annual Report of Council. On the social side there can be no doubt that Eastbourne will live up to its reputation as a centre of health and hospitality, and a warm welcome is assured from the mayor and corporation, from the local profession, and from the townspeople generally. The provisional time-table for the whole meeting is printed in our *Supplement* this week, together with the programmes of the fourteen Scientific Sections, which meet on July 22nd, 23rd, and 24th. A casual glance through the list of set debates and papers gives the impression that the sectional officers have held a just balance between the claims of every-day clinical work and the desire of the specialist for opportunities to cultivate his own arcana. They have also kept in mind, once again, the advantage of concentration upon a limited number of topics, though, taken as a whole, the fourteen programmes cover a very wide field of medical science and practice. It will be seen that every Section has arranged this year for one or more discussions on matters of direct interest to the general practitioner, and that several of the thirty-six discussions—for example, in the Obstetrical Section on breech labour, and in the Pathological Section on milk-borne diseases—are to take the form of comprehensive reviews in which each principal speaker is allotted one subdivision or one aspect of the subject.

Every member who notifies his desire to visit Eastbourne six weeks hence, and is able to obtain rooms at that busy season, can look forward to an agreeable and interesting time. Some of the most successful Annual Meetings of the British Medical Association have been held at South Coast resorts, and, indeed, there is a quality in sea air that lends invigoration to congress proceedings. London has not this advantage, and it must hope by other means to rise to the great occasion next year, when the Association, after a pious pilgrimage to its birthplace, Worcester, celebrates its centenary in the metropolis of the British Empire under the presidency of Lord Dawson.

RECENT RESEARCH ON VITAMINS

The first edition of *The Vitamins*, by Professor H. C. Sherman and Dr. S. L. Smith, appeared in 1921, and a second edition[1] now follows after an interval of ten years. This interval represents half the present age of the subject, and the opportunity may be taken to consider what general trends are revealed by a comparison of the two editions. The present edition has been almost completely rewritten, but it is interesting to note how many of the facts of outstanding physiological importance were already established in 1921. Only one new vitamin has been discovered since that date—namely, vitamin E—and this is distinctly less important than its associates. Most of the principal physiological actions of the other five vitamins were known in 1921, and the two most significant new facts that have been added are the identification of the anti-pellagra vitamin with the water-soluble vitamin B_2 or G, and the fuller knowledge of the anti-infective action of vitamin A. On the other hand, chemical knowledge of the vitamins has been revolutionized during the last decade. Practically nothing was known in 1921 of the chemistry of the vitamins, and they were regarded as being substances as mysterious and elusive as the bacterial toxins. To-day the chemical nature of three of the vitamins is apprehended with some degree of certainty. We know that vitamin A is elaborated by the body from the plant pigment carotene, and that vitamin D can be produced from ergosterol by irradiation with ultra-violet light either *in vitro* or *in vivo*. Finally, vitamin B_1 has been isolated in crystalline form; its probable chemical structure is known, and attempts have been made to synthesize it. The chemical nature of the other three vitamins is less well understood, but great advances have been made in their concentration and isolation, and the discovery of their constitution can be only a matter of time. The centre of interest in vitamin research has therefore shifted from the physiological to the chemical aspect. During the years prior to 1921 a new field of physiology was rapidly explored and the general physiological actions of the vitamins were established, whereas during the last decade the chemistry of the group has been partly worked out. One of the chief results of the chemical work has been to show that there is little or no chemical relationship between the members of this class, which were grouped together by the physiologists.

[1] *The Vitamins.* By H. C. Sherman and S. L. Smith. Second edition. American Chemical Society Monograph Series. New York: The Chemical Catalog Co., Inc. 1931. (6 dollars.)

There was indeed no reason to expect any close relationship, but the extreme diversity of their chemical structure is rather remarkable. This diversity has, of course, been an embarrassment to Professor Sherman and Dr. Smith, for, as they point out, there is little or no relation between the chemistry of the different members of the class that they discuss, and yet the greater portion of their monograph is occupied with this subject. It seems probable that future monographs will be limited to a single vitamin, although this method will be rendered difficult by what may be called the tendency to fission shown by vitamins. Vitamin B has been divided into two clearly distinct factors, and there is already evidence for the existence of three other subdivisions. The bulk of the literature will, however, automatically impose a limit on the scope of monographs on vitamins. In their 1921 edition the authors brought together 1,000 selected references, and it was felt that the subject was even then in danger of being crushed by the weight of its own literature. The 1931 edition ends with a bibliography of 3,000 references. This occupies 180 pages, and, together with the index, constitutes two-fifths of the volume. The day seems not far distant when the production of a monograph will consist in writing a bibliography and adding the text. Meanwhile, Professor Sherman and Dr. Smith are to be congratulated on the skilful manner in which they have dealt with this unwieldy mass of literature, and have produced a clear and authoritative account of all the chief work done on the subject until the middle of last year.

THE WAKING HOUR IN HOSPITAL

The hour at which patients in hospital are aroused in the morning has been brought before the public more than once during recent months. In 1929 Middlesex Hospital announced its introduction of the 7 o'clock breakfast, with the rule that no patient was to be washed or disturbed beforehand unless for urgent medical reasons. In the spring of last year the Central Bureau of Hospital Information published a memorandum, which was the subject of comment in these columns (May 3rd, 1930, p. 832), summarizing the practice in this respect at sixty-three large provincial hospitals. In forty-five of these institutions the work in the wards began earlier than 6 a.m., and in thirteen others precisely at that hour. More recently a report was presented to the London County Council by its Central Public Health Committee on the subject as it related to former Poor Law hospitals which had newly come under the control of the Council. In ten out of the twenty-eight waking took place before 5 a.m., and in the others, between 5 and 6. It was then laid down that, as far as practicable, in London county hospitals the patients should not be aroused, except in special circumstances, before the hour of 6. King Edward's Hospital Fund for London now publishes the report of a committee, of which Mr. Walter G. Spencer was chairman, summarizing the information received from the Fund's visitors as to the hours of waking in the 141 hospitals in and around the metropolis which the Fund assists. In four of these the earliest hour mentioned by the visitors is 4 to 4.45 a.m. ; in sixty-two it is between 5 and 5.45 ; in forty-four it is 6 ; and in fourteen later than 6. The few remaining hospitals are mostly small institutions for children and babies, where there is no fixed hour. At six out of the twelve teaching hospitals 6 a.m. is the regular hour ; at four it is between 5 and 5.45, and at the other two it is up to 6.45. At the nine maternity hospitals the hour is between 5 and 6. The announcement of these early hours—although in London the hour of waking is, on the whole, later than in provincial hospitals—has been the subject of some indignant comment in London newspapers. We fully agree that it is most undesirable by adherence to arbitrary rules to rob the patient of early morning slumber. Even to the healthy person, with the day's work in front of him, the reactions to the morning call, the toilet, and the breakfast are delicate affairs which may affect the pattern of the day ; much more so in the case of the person made unduly sensitive to small things by physical debility and withdrawal from active life. But the matter is not quite so simple and manageable as some critics of hospital administration suppose. Various processes have to be undertaken in the wards, such as the washing of patients, the making of beds, and the serving of food, and the time occupied differs with the case. A sufficient interval must elapse between breakfast and the light mid-morning lunch. Work in the wards must be completed before the visits of the medical officers, which usually begin at 10 o'clock in London, though an hour as early as 9 is mentioned in the provinces. All these matters are open to fresh adjustment, but a larger consideration is the division of work between the night and day nursing staffs. As it is, the staffs overlap in the morning usually for an hour or an hour and a half. It has been said, in defence of early waking, that hospital patients are a class accustomed to early rising, so that any hardship is minimized. But apart from the fact that it is one thing to rise to a day's labour or a day's play, and quite another thing to awake to a day's quiescence or immobility, we doubt very much whether, now that the factory sirens sound at 8 or after, the hour of rising of working-class people is anything like as early as 6, to say nothing of 5. The exigencies of a great institution have, however, to be borne in mind, and certain definite suggestions are put forward in the King's Fund report for consultation with the hospitals. The committee expresses the view that unless there is some exceptional and adequate reason to the contrary, the most suitable hour is 6 o'clock. It is believed that the adoption of 6 as the waking hour could be effected without material increase of staff or expenditure by hospitals which have been accustomed to rising earlier ; even if a small increase of staff is necessary, the committee think it justifiable in view of the gain to the comfort of the patients. A further suggestion is that breakfast should be served as soon as possible after the hour of waking ; that no patient should be washed before having either breakfast or early morning tea ; that work involving disturbance of the patients before breakfast should be limited to whatever is necessary for their comfort, and that any noise in the ward before 6 o'clock should be avoided. There is nothing mandatory about the suggestions, but no doubt they will receive the careful consideration they deserve, both because of their reasonableness and because of the source from which they come.

SEROLOGICAL AND INTRADERMAL TESTS FOR FILARIASIS

Dr. N. Hamilton Fairley has recently described two new tests for filariasis.[1] An intradermal skin test for *Filaria bancrofti* was described by Taliaferro and Hoffman in 1930, and this has now been confirmed and extended to the diagnosis of *Loa loa* and *Onchocerca volvulus*. The antigen for this test was obtained by Dr. Carmichael Low from Dr. Le Sueur in Borneo, and was made from living *Dirofilaria immitis* worms, which were collected from the right heart of dogs immediately after they had been killed. The worms were chopped up and dried in a desiccator, and ground in a mortar to a fine powder, which was finally sent to England. In addition to the intradermal test, Dr. Fairley now describes a new serological one—namely, a complement-fixation reaction, for the filarial group of diseases. A technique similar to that described for bilharzia cercarial antigen (Fairley, 1930) was employed, and those interested in the details should consult the original paper. Both the intradermal and serological reactions are essentially group reactions, the scope of which probably includes all species of the family *Filariidae*; and the clinical and theoretical aspects of the combined reactions, Dr. Fairley believes, will afford an entirely new and valuable mode of approach to the clinical study of filariasis. They will also furnish a means of differential diagnosis between real filarial diseases and the non-tropical conditions which sometimes simulate them. Again, their application to cases of tropical elephantiasis will be of the greatest value in determining whether or not *Filaria bancrofti* was responsible for the onset of the condition. The discovery opens up a new field of investigation in this interesting group of tropical maladies, and readers will look forward to the larger paper which is in course of preparation, and which will amplify the preliminary observations contained in the present note.

BIOLOGICAL STUDIES OF APICAL INFECTION

With the assistance of a grant from the Medical Research Council Mr. Arthur Bulleid has made a systematic study of the bacteriology of "apical infection"[2]—one of the most important and most debated points of dental pathology. The inquiry was divided into four main subdivisions: apical granulomata, chronic apical osteitis other than apical granulomata, acute alveolar abscess, and cystic new growths. The net result was to confirm the generally held opinion that apical granulomata and apical osteitis are foci of possible infection, to incriminate streptococci as the cause of acute abscess, and to suggest that the dental cyst, throughout the whole course of its existence, carries a residue of the original infection which started its growth. This last is an interesting and rather unexpected finding, since the clinical symptoms of a dental cyst give no hint of persistent infection; it is a point that requires further investigation. In all the subdivisions Mr. Bulleid concludes that the chief causative factor is a streptococcus, though in the case of granulomata it may be accompanied by a staphylococcus. The numbers dealt with, and the careful methods of investigation and recording adopted, fully justify the conclusions presented by the author, and it would seem that they will be difficult to controvert. In general, his meaning is clear, but there are one or two obscure passages. What, in particular, was the special interest of the four live teeth showing absorbed apices in the skiagrams, and where was the primary focus that had healed before the absorption of the apices had taken place (p. 17)? It is interesting to note that the efficacy, or even the advisability, of root-filling is seriously brought into question by the author as one result of his investigations. We congratulate the Medical Research Council on a well-placed grant.

BATS

The American National Institute of Health is engaged in publishing a series of bulletins which form the third part of the well-known *Index Catalogue of Medical and Veterinary Zoology*. The first two parts dealt with authors and with subjects; the present part deals with hosts. The first five members of this series have listed the parasites and vectors of disease to man; the sixth, which has just been issued, considers the first of the groups of lower animals—the bats.[1] So far as is at present known, the public health importance of this very specialized group of mammals is distinctly limited. At least one species, in the Far East, is eaten as food; in America, however, another group uses man as its food. Vampire bats are well known in literature, but it is not always realized that such animals actually exist. In Trinidad, for example, they are a well-known pest to both man and domestic animals. Planters are put to a considerable expense in some localities in making sheds and stables "bat-proof," while in some of the islands human beings are not infrequently bitten during the night. The bite is painless, but bleeds profusely, and is generally on the foot, where it has been pushed against the mosquito net. The animals are easily kept away by even a small light in the room, and the actual damage done is slight, though the psychological effect may be considerable. The vampires belong to a single family, the Desmodontidae, which is specially adapted for a blood-sucking habit; the so-called "false-vampires," or Vampiridae, are fruit-eating bats, and cannot feed on blood. It is commonly believed that bats are distributors of bed-bugs, but while a species of Cimex actually does infest bats and bat-haunts, it is quite distinct from the human *Cimex lectularius*. The bats cannot play much part in connexion with the transmission of disease to man, but in view of recent investigations into several rodent diseases, like tularaemia and Rocky Mountain spotted fever, it is not safe to dogmatize. Certain human parasites have been transmitted experimentally to them—such as leishmania, trypanosoma, and *Treponema duttoni*—and a number of ecto-parasites which infest man have been reported as occurring naturally on bats—such as various fleas and ticks. On the other hand, many species of bats devour insects, including mosquitoes, and doubtless they form one of the natural factors which serve to control these pests; and it is possible that

[1] United States Government Printing Office, price [illegible] the Superintendent of Documents, Washington, D.C.

they may serve as useful laboratory animals, as some species can be easily tamed and kept in captivity. The bulletin classifies all the animal parasites which have been recovered from bats, as well as the bats themselves. Like its predecessors, it is a model of compactness, and will be invaluable to all who work in medical zoology.

DUTCH TRIBUTE TO SIR ROBERT JONES

On May 21st a small but sympathetic company, consisting among others of the director, Dr. Murk Jansen, Mr. Alan Todd of London, Mr. Harry Platt of Manchester, and the staff of the hospital, assembled in the hall of the Anna Clinic of Leyden, in front of which hung the British flag. The occasion was the unveiling of a bronze plaque, by R. Lubach of Zeist, of Sir Robert Jones, who was present. After the British National Anthem had been sung by the nurses' choir, Dr. Jansen, speaking in the name of the Dutch Society for the Deformed, paid an eloquent tribute, first in English and then in Dutch, to his old friend, extolling his influence as a teacher, his organizing ability, and his kindness of heart. The plaque, he said, had been placed in a prominent position in the hospital to serve as a stimulus to the members of the staff. Sir Robert Jones, in his reply, expressed his deep appreciation of the honour done him, and described Dr. Jansen as a master surgeon and a champion of peace. The ceremony ended by the choir singing the first verse of Psalm 134.

THE DANCE OF DEATH

Most travellers have seen the Dance of Death as it is represented in frescoes in various churches and public buildings both at home and abroad; more often, perhaps, in Germany and Switzerland than in France and England. Beginning as a morality play in the thirteenth and fourteenth centuries it passed gradually into art, for as a *memento mori* it was too valuable an instrument in the hands of the clergy to be allowed to die out completely. Originally grotesque and horrible, successive artists softened its cruder features until Albrecht Dürer idealized it, and Alfred Rethel, in the middle of the last century, made it a poetical dream. Hitherto Mr. Francis Douce, the antiquary, and Dr. Parkes Weber have been the chief authorities to be consulted by those who needed information, but though their facts are correct they have considered the *Danse Macabre* as a whole, and the subject is immense. Dr. Aldred Scott Warthin, professor of pathology in the University of Michigan, has adopted a different method. In *The Physician of the Dance of Death*[1] he has taken a single figure—the physician—and has traced him through the entire series of representations from the early days to the gross caricatures of Rowlandson and Cruikshank. The result is eminently satisfactory. It shows what manner of man the physician was thought to be at different periods, and gives minute details about his dress and habits. On the whole he does not come out very well: covetous, often a quack, overfed, and not too mindful of his patients, in the Middle Ages, but gradually coming into his own as his education improved, until in the latest representations he is shown as the cultivated scientific man of the present day. The work has evidently been a labour of love for Dr. Warthin. He began it in 1893, when he bought Albrecht Dürer's "Ritter, Tod, and Teufel" in a printshop at Nuremberg, and gradually followed it up until he was able to produce a most satisfactory bibliography of 280 items, printed at the end of the present volume, a bibliography which shows that he has not only consulted most of the books written upon the subject, but actually has a large number of them in his own library. *The Physician of the Dance of Death* began as a series of papers contributed to the *Annals of Medical History* in 1930 and 1931. They are now republished with additions, corrections, and more illustrations. The book, therefore, is of outstanding and permanent value, and it is a pity that only 1,000 numbered copies have been printed.

[1] *The Physician of the Dance of Death.* By Aldred Scott Warthin, Ph.D., M.D., LL.D. New York: P. B. Hoeber, Inc. 1931. (7.50 dollars.)

B.C.G.

We publish this week at page 986 an impartial review of the circumstances of the B.C.G. tragedy at Lübeck, so far as these have been brought to light, together with some discussion of the difficulties in the way of any attempt to elucidate the affair. The time seems opportune for such a presentation, because Professor Calmette is visiting London next week, and on the evening of Tuesday, June 9th, he will read a paper before the Royal Society of Medicine on "B.C.G. immunization of infants."

STEPHEN PAGET LECTURE

The annual general meeting of the Research Defence Society will be held at the house of the Medical Society of London, 11, Chandos Street, Cavendish Square, W.1, on Wednesday, June 10th, at 3.30 p.m., with the president, Lord Lamington, in the chair. An address will be delivered by Dr. H. H. Dale, F.R.S., director of the National Institute for Medical Research, on "The effect of research on curative medicine," being the fifth Stephen Paget Memorial Lecture.

Professor D. P. D. Wilkie of Edinburgh University has accepted an invitation to act as Director of the Surgical Professorial Unit at St. Bartholomew's Hospital during the first fortnight in June. He is taking over the duties of the professor of surgery during that period and also lecturing to the students. It will be remembered that on previous occasions Professor Harvey Cushing, Professor Hugh Cabot, Lord Moynihan, and Professor Grey Turner have accepted similar invitations at St. Bartholomew's.

Professor G. Grey Turner of Newcastle-upon-Tyne is paying a visit to Boston, U.S.A., to receive in person the H. J. Bigelow Medal, and to deliver an address on "Some personal experiences in oesophageal surgery."

At a meeting of the Optical Society on June 11th at 8 p.m., in the Imperial College of Science and Technology, South Kensington, the Thomas Young Oration, entitled, "Young's theory of colour vision," will be delivered by Sir John H. Parsons, F.R.C.S., F.R.S.

SMALL-POX PREVENTION AND THE VACCINATION ACTS

We have received from the Ministry of Health a memorandum on the present position regarding small-pox prevention in England and Wales in its relation to the Vaccination Acts.*

At the beginning of the report it is remarked that the prevalence of small-pox has long been considered as eminently preventable and the disease as one which "in view of its nature, and of the prophylactic means which we possess, should be banished from a civilized community which is reasonably organized for the care of the public health. There has been, and in a sense there still is, ample justification for looking at small-pox in this way." It is taken as "beyond the necessity of proof that individuals exposed to small-pox infection, however intense and whatever its type, will escape attack if at the time of the exposure they have already been recently and successfully vaccinated, and that they will in all probability escape attack, or only suffer from a very modified attack, if they can be successfully vaccinated within forty-eight hours following exposure."

Statistics are provided of mortality from small-pox since 1855 and of the practical immunity from small-pox of attendants in small-pox hospitals who have been vaccinated. It is next pointed out that, of recent years, infant vaccination has been decreasingly used and the prevalence of small-pox has increased, but the type of the latter has changed greatly, being manifested, if not as a relatively trivial disease, "at least as one that hardly ever has a fatal result, leaves very little disfigurement, and has few complications."

Reasons are adduced for terming the variety of small-pox mainly prevalent since 1923 variola minor, and its clinical characters are described. This form is probably identical with the variety described as long ago as 1722 by Wagstaffe. Statistics are then presented showing that at present countries may be classified as (1) those wherein the old virulent form of small-pox still prevails—India and the Far East are examples; (2) those wherein at present the prevailing strain is non-virulent—the West Indies, parts of the United States of America and Canada; (3) those wherein both types coexist—England, Brazil, and some of the Southern States of North America. In the next section, current administrative measures of control are described. These have proved eminently successful in the control of major small-pox.

"In a word, subject to consideration of the details referred to above, we have been able, almost since the beginning of the century, to think of major small-pox as a rare, exotic disease which we effectively hold in check and extinguish when it appears. We can complacently contrast our position in this respect with that of any other country in the world, and there is no reason why we should not continue to do so."

In the next section variola minor is considered, and, although the success of the usual administrative measures in many instances seems to have been rendered probable, it is noted that general control has not been attained. Many reasons exist for this failure, such as the difficulty of unrecognized cases and the reluctance of contacts and others to submit to vaccination in view of the mildness of the disease. It is pointed out that deliberately to treat variola minor as in the same category as chicken-pox would lead to internal and international difficulties. An individual patient with an extensive rash may be an unpleasant object, while international obligations with respect to notification must be respected, and some foreign authorities are sceptical as to the difference between the two forms of variola. The memorandum next considers the measures appropriate to the situation when variola minor occurs within a district. It does not seem that, when the disease first appears, any essential change of the present procedure is needed. When the disease has gained a footing, what action should be taken must be a matter for local decision.

"It can, however, be said that, to judge from the reports received from districts in which variola minor has been for some time epidemic, local authorities need not, and should not, carry on the work on the principle that all the procedures which would be applicable in the case of a major small-pox epidemic must necessarily be applied to the minor."

It is a matter for consideration whether patients suffering from variola minor need always be isolated in a hospital admitting no patients suffering from diseases other than small-pox. Co-operation between the public health staff and medical practitioners is of great importance, and the practice of arranging for consultants with special experience is commended. It may prove advisable only to attempt to secure vaccination of direct contacts, and the current practice of tracing contacts might be simplified.

The next section contains a précis of knowledge respecting post-vaccinal encephalitis. In the following section the advantages and disadvantages which local authorities derive from the Vaccination Acts in regard to control of small-pox are considered. Actually the effect of the Acts is limited to vaccination in infancy, and to the extent to which they are complied with result in the conferring of a high degree of immunity upon a section of the population. Under the most favourable conditions this might amount to 15 per cent. of the population, on the average perhaps 9 per cent. Another advantage is the utility of the public vaccinator, who has been available at all times and whose returns to the Government Lymph Establishment have been of great value, while public vaccinators specially appointed have had the duty of instructing medical students in the technique of vaccination. It is suggested that the value of these advantages has diminished under present conditions, and possible alternatives are considered. The essential point is that if the rigidity of the present system were modified and vaccination thought of not as an end in itself but as a measure "which the individual should be advised and assisted to adopt for himself and for his children at several stages of life with the idea of maintaining himself and them at a reasonably high degree of immunity at all times," it might be found expedient to utilize the many opportunities which present themselves to the public health authorities to educate the public.

"It may be claimed that an authority which desired to promote vaccination through its public health department on some such lines would at least succeed in producing a more satisfactory effect as regards protection of its population by systematic vaccination than it could obtain by the strictest application of the obligatory clauses of the Vaccination Acts."

An appendix to the memorandum contains notes on the vaccination requirements of certain European countries.

* Reports on Public Health and Medical Subjects. No. 62. A Review of Certain Present Aspects of Small-pox Prevention in Relation particularly to the Vaccination Acts, 1867-1907. London: H.M. Stationery Office. R.31. (1s. net.)

The German, Austrian, and Hungarian members of the International Society of Surgery, who were excluded in 1920, have recently been reinstated, Professor de Quervain of Berne and Dr. Shoemaker of The Hague acting as intermediaries between the International Society and the German Society of Surgery. The next congress will be held at Madrid in 1932.

MENTAL HOSPITAL ACCOMMODATION

An important circular on mental hospital accommodation was issued on May 30th to local authorities by the Board of Control. The principal points to which the Board draws attention are as follows:

The Mental Treatment Act came into operation on January 1st, 1931, and as the facilities for mental treatment without certification under the Act become more widely known, there may be an increasing demand for treatment under those provisions, which will necessitate a review by local authorities of the accommodation available. At the same time the shortage of mental hospital accommodation generally has become acute, and will oblige many local authorities to consider what steps should be taken if they are to maintain a reasonable standard of efficiency and progress in this service. Though there is no increase in the incidence of mental disorders, the number of persons under care continues to grow because the total population and the average age of the population are both increasing.

There is now practically no margin of accommodation in the public mental hospitals. On January 1st in the present year, there were only twenty-seven hospitals with ten or more vacant beds on the male side, and nineteen with ten or more vacant beds on the female side. There are practically no unoccupied beds, the use of which authorities can obtain by contract with other authorities. Moreover, the practice of taking beds on contract, though useful in special circumstances, is strongly to be deprecated if it involves sending patients so far from their homes as to make visiting by their relatives prohibitive by the expense of travelling.

The standard of accommodation laid down by the Board is a minimum standard based on long experience, and a departure from it would be injurious. Overcrowding is not only bad for the patient's mental and physical condition, but imposes unnecessary strain and may involve danger for the nursing staff. Local authorities will therefore have to consider increasing the accommodation for mental patients, and there are two main ways in which this can be done—either by redistribution of patients among the various types of institutions now under the control of the local authority, or by the provision of new mental hospitals.

As regards redistribution there are four possible alternatives:

1. The utilization of beds in public assistance institutions for the quiet chronic cases or senile cases, whose condition does not necessitate treatment of the kind that can only be given in the relatively more expensive beds of a mental hospital.
2. The removal from mental hospitals of mental defectives, who can be far more economically provided for in Poor Law premises or in mental deficiency colonies.
3. The granting of leave of absence on trial and boarding out, or discharging suitable patients to the care of relatives or friends.
4. The provision in connexion with an existing mental hospital of an admission unit and convalescent villas where these do not already exist.

In this connexion it is pointed out that every mental hospital, whether full or not, should have this accommodation, which has become imperatively necessary in view of the provisions made for the treatment of voluntary and temporary patients under the Mental Treatment Act.

The second main alternative is the construction of new mental hospitals, and the Board points out that there will be some authorities who will find themselves compelled before long to build such institutions. Local authorities who have no right of ownership in any mental hospital, and who, therefore, have to secure by contract beds for patients for whom they are required to provide accommodation, are particularly concerned with this aspect of the question. As the shortage of accommodation generally becomes more acute, notices terminating existing contracts are being given, and some authorities will have no alternative but to make provision themselves. The circular suggests that the problem could best be approached by means of local regional conferences, when consideration might be given to the possibility of uniting for the purpose of providing a joint mental hospital. It is the Board's intention to stimulate the holding of such local conferences for this purpose; and the circular has been issued to assist the local authorities in envisaging the main considerations which should determine the extent and nature of any additional accommodation that may be necessary.

Where new buildings prove to be essential, the expenditure involved is not likely to be serious, and in most cases would represent only a small fraction in the local rates. The provision of accommodation for the insane is, moreover, a statutory obligation which local authorities are bound to meet, and the purpose of the circular is to assist local authorities in framing plans to meet the existing shortage in a manner which will be, in the long run, conducive to the most efficient and economical administration of the service.

Scotland

Mental Defect in Scotland

A conference was held in Glasgow on May 22nd, under the auspices of the Scottish Association for Mental Welfare. Dr. J. Parlane Kinloch, Chief Medical Officer of the Department of Health for Scotland, who presided and delivered the opening address, said that they had to get back to the old Greek ideal of healthy childhood and youth. They had to recognize that for the living child there must be a rhythmic exercise of the mind alternating with a rhythmic exercise of the body. He thought that such an arrangement during school hours would, in the course of four or five years, produce much greater mental efficiency than six hours of steady educational work daily. A paper dealing with mental deficiency was read by Dr. R. D. Clarkson, medical superintendent of the Royal Scottish National Institution, Larbert, who estimated that if the percentage of mental deficiency in Scotland was similar to that in English areas the total number of mental defectives in Scotland was about 40,000. Mental deficiency therefore constituted one of the greatest of social problems, and they should shrink from no measures, however drastic, to prevent it. He believed that injuries to the brain at birth were responsible for a large number of cases. Not all of these cases could be prevented, but much might be accomplished by emphasizing the necessity for ante-natal care and by raising the standard of education of medical men and midwives. Just as the growing body required small quantities of vitamins, whose nature and function were still obscure, so the mind required what had been called "psycho-vitamins," including family affections, moral principles, and religious belief. Recognition of this fact was essential for the success of any campaign of mental hygiene. In discussing the question whether other cases of mental defect could be explained by the action of innate, intrinsic, or hereditary causes, Dr. Clarkson said he did not think that heredity played a large part; it was impossible to imagine that mental defect was a unit character like the colour of the hair or of the eyes. It had been urged that the feeble-minded should be segregated, but they could not afford to segregate 40,000 persons. They did, however, need more boarding schools for defective children and more industrial colonies for adult defectives than they had at present. Dr. R. M. Marshall, consulting neurologist to the Glasgow Education Committee, who gave an address on the ascertainment of mental defect, considered that in determining idiocy the criterion of inability to

guard against common physical dangers was a valid one. In the ascertainment of imbeciles their failure to manage themselves or their affairs was not a very satisfactory guide, the crucial test of trial for a year being always advisable in special classes. In regard to the feeble-minded the criterion should be a purely scholastic one, and the question of social adaptability should be considered only when it was raised by the conduct of the individual. Indications for notification to the Board of Control of feeble-minded persons at the age of 16 should be based upon the educational and intellectual life of the child. Dr. D. Yellowlees, Glasgow, suggested that one of the functions of the association was to recognize that the human mind was living and moving purposefully. The primary force behind it was that of primitive instincts, and healthy mental development meant that these primitive forces and tendencies were being organized, sublimated, and directed towards aims in a real outside world. One of the objects of the association was to create a public conscience regarding the mental influences offered to children, whose selective powers were in process of development. In this connexion he stressed the importance of quality in the provision of cheap reading matter and of cinematograph films.

Scottish Nursing Conference

In opening the conference in connexion with the Scottish nursing, hospital, and health week, held in Edinburgh from May 24th to 30th, Lord Provost Whitson said that it was designed to provide a refresher course for nurses of all departments, and had a special appeal to all engaged in public health activities. Statistics indicated that the nursing profession was a healthy one; it was the only profession in which emoluments were included during education, and it had the further advantage that the knowledge and experience acquired in the course of training was often useful in domestic life. Unlike other professions there was no unemployment if a nurse was physically fit. Dr. J. Parlane Kinloch of the Department of Health for Scotland, in the course of an address on "The future training and organization of nursing," said it was obvious that four great training schools for nurses would in future be associated with the four regional medical schools at Edinburgh, Glasgow, Dundee, and Aberdeen, and that every hospital and clinic in these centres must be orientated towards this training. It was desirable that after leaving school the prospective nurse should engage for a period of eighteen months in acquiring a knowledge of the principles of biology, pathology, chemistry, anatomy, physiology, and dietetics. She would then be ready to enter on a three years' training in hospital, followed perhaps by specialization. He thought that the new organization of the hospital community, devised under the Local Government Act of 1929, would provide a complete training for an adequate health and nursing service. In a paper on "The problem of training the nurse," Dr. John Guy stated that in some places there was an arrangement between the general and fever hospitals by which a three years' preliminary training in a fever hospital was accepted as equivalent to one year's general training. This meant that before certificates in general nursing and fever nursing could be obtained six years must be spent in hospital; if, in addition, a nurse desired a certificate in children's work, a certificate of the Central Midwives Board, and training in mental welfare, she must spend altogether some eight or nine years in work and study. It appeared, therefore, that the time was more than ripe for a co-ordination of training in the various branches of nursing, and that the matter should be considered by a conference of municipalities, which were the largest employers of nurses. He thought that for an all-round training, two years of general medical and surgical work, one year of fevers, six months of tuberculosis, and six months of mental work, would suffice. Dr. James Young, in an address on "The prevention of maternal mortality and disability," said that every year in these islands over 4,000 women died from child-bearing, a ratio of about 5 per 1,000 births, and it had been computed that for every such death at least ten women suffered from ill-health every year by this cause. These cases represented about 50 or 60 per cent. of the patients treated in the gynaecological departments of general hospitals. The factors that contributed to this maternal disability naturally prejudiced the child, and in this connexion it was noteworthy that while recent advances in public health had led to a rapid reduction in the death rate of infants during the first year of life, the death rate among newly born infants remained practically stationary. In his opinion a great part of this annual mortality and impairment of health could be prevented, a fact which was proved by widely varying death rates in different parts of the country. The nine hundred or more ante-natal centres that had been set up throughout the country had failed to reduce the mortality, mainly because the importance of ante-natal care was not sufficiently realized. The necessary rest at home was often unprocurable, and it was gradually coming to be recognized that a national maternity service which would provide every woman with a midwife or doctor and, if need be, the services of a hospital, was essential. Dr. W. M. M'Alister, medical officer in charge of mental health services under the Corporation of Edinburgh, speaking on "Modern methods of treatment in dental disease," said that the ideal of modern treatment was prevention. With this in mind, intensive study of the antecedents of insanity, whether hereditary or environmental, contact with and treatment of abnormal mental tendencies at the earliest possible stage, and the provision of machinery for achieving these two aims, were the necessities of the present time. The make-up of the individual must be carefully studied, along with influences of home and companions, and of the general physical condition. In ascertainment and treatment the psychologist must join hands with the social worker. Psycho-analysis had illuminated the whole range of mental disorders, but in practice it had serious limitations, the most obvious being the necessary co-operation of the patient. Great care had to be taken in choosing cases for psycho-analysis, because mental crises might be precipitated by an attempt to analyse a patient who was not a suitable subject. Very often something less pretentious than formal psycho-analysis gave just as good curative results. He believed that in the prevention of mental disease it was impossible to over-emphasize the importance of examining the mental as well as the physical state of the child, and for this purpose children's clinics should be established in each of the large centres. These centres should also have an out-patient clinic associated with the general hospital, which should devote a certain number of beds for the observation and treatment of mental cases. Dr. A. S. M. Macgregor, medical officer of health for Glasgow, who delivered an address on "Maternity services," said that the scheme for the provision of home helps had been in operation in Glasgow since 1924, and had met a definitely felt want. The Public Health Committee of Glasgow had employed 17 women in this way up to the end of 1925; since then the demand had been increasing, and in 1930, 204 helps were provided for households in which there were children under 5 years of age. The importance of the service of midwives over be gathered from the fact that in Glasgow year on an there were 24,500 births, of which one

institutions and 4,000 were supervised by outdoor maternity services from institutions. Of the remaining 16,500, 9,600 were managed by midwives alone. Thus of the total births, 40 per cent. were conducted by midwives in the homes of the people and 26 per cent. by medical practitioners. It was now coming to be regarded as desirable that midwives should possess a general nursing qualification. The addition of puerperal pyrexia to the list of notifiable diseases had had the effect of increasing the 516 cases of puerperal fever notified in 1929, to 598 notified in 1930, with the addition of 235 cases of puerperal pyrexia. He looked forward to the time when it might be possible to produce a code of precautions which would make puerperal sepsis as rare as severe ophthalmia neonatorum.

Edinburgh University

At a meeting of the University Court of Edinburgh University, on May 25th, Dr. Sydney Smith, professor of forensic medicine, was appointed dean of the Faculty of Medicine in succession to the late Professor Lorrain Smith. Professor Smith was also appointed the University representative on the General Medical Council. At the same meeting it was intimated that Dr. Walter Smith Kay, who died on April 22nd, had bequeathed to the University a sum of £5,000, of which the annual income was to be applied towards aiding research in mental diseases or psychiatry. Dr. Kay graduated M.B. at Edinburgh in 1877, and was formerly medical superintendent of the asylum at Wadsley, Sheffield.

England and Wales

Voluntary Hospital Progress

King Edward's Hospital Fund, which assists 141 hospitals within an eleven-mile radius of St. Paul's, has adopted the method of setting out on coloured charts, which are issued as leaflets, the financial position of the hospitals, the sources of their revenue, and the extent of their services over a period of recent years. All the curves have an upward character, except the one representing revenue from legacies, which fluctuates from year to year. During the five years 1925–29 both the general expenditure and the general income of the hospitals of the metropolis as a whole rose by about half a million. The income from voluntary gifts is still the largest source of hospital revenue, followed closely by payments on account of services rendered. In 1929 a sum of £1,378,000 was received by way of subscriptions and donations, and £1,214,000 by payments for services, of which the greater part was made by patients, either as voluntary payments or through contributory schemes, and the remainder by payments by the public authorities. Interest on investments now represents about 17 per cent. of total income. Hospital finance is more or less a reflection of the charitable resources of the community, but the figures which illustrate the services that hospitals are performing show consistent increase also. Thus the number of beds in the voluntary hospitals of London has increased in five years by about 2,000; the actual number of in-patients treated by nearly 40,000; and the out-patient attendances by 1,150,000. An increase in the number of pay-beds is also shown. There are now 1,425 such beds distributed among 99 of the hospitals on the list of the Fund, and with the developments promised at the West London and other hospitals, this number is likely to be largely increased in the near future. A few words may be added about the Fund itself. Although it bears the name of King Edward, it dates back to the year of Queen Victoria's diamond jubilee, when it distributed £50,000 to 97 hospitals. In 1930 its ordinary distribution was £266,000, and to 141 hospitals, not counting 57 convalescent homes. The hospitals on its list include the 12 teaching hospitals, between 50 and 60 general hospitals, including cottage hospitals, and between 60 and 70 special hospitals. Apart from special efforts, the ordinary annual grants have risen steadily almost year by year, until in 1928 and 1929 they touched a quarter of a million, a figure which in 1930 they surpassed. In addition, in 1929, the Thank-offering Fund for the King's recovery, amounting to £115,000, was distributed.

Cave-dwellers of Derbyshire

Under the auspices of the Warrington Division of the British Medical Association a lantern lecture on the cave-dwellers of Derbyshire was given in the Warrington Infirmary on May 20th by Mr. A. Leslie Armstrong, F.S.A. He dealt with the occupation of Derbyshire caves by man in the earliest prehistoric periods, and pointed out that the caves had been almost consistently occupied from before the great Ice Age onwards. The Marlborough Cave, near Brassington, though not very rich in relics, was a good example, since an examination had revealed an occupation of early Palaeolithic date, and in succession men of the Stone Age, Bronze Age, Iron Age, and Roman period had lived there. It was known to have been the haunt of highwaymen. The most important cave so far explored in Northern England was the Pin Hole Cave at Creswell Crags, on the borders of Derbyshire and Nottinghamshire. The Creswell Gorge was about a quarter of a mile in length, and contained five large caves, four of which were examined and their contents removed over fifty years ago. Fortunately the Pin Hole Cave was left practically intact; it was the only one in the series which could have contained the complete story of occupation during prehistoric times. Mr. Armstrong said that he started work there seven years ago under a joint committee of the British Association and the Royal Anthropological Association, with important results. It was interesting as the most northerly place where traces of Palaeolithic occupation had been found in England. There were two layers of cave earth, with a total thickness of seventeen feet, all of which had been systematically examined, layer by layer. In the cave there were three zones of occupation by men of the Mousterian Era, representing the earliest known traces of humanity in Derbyshire; two dated from a period of time long before the oncoming of the last great Ice Age. In the upper cave earth a series of occupations was revealed by men of late Palaeolithic times, terminating in a cold, wet period which seemed to synchronize with the final cave period of France and Europe, and was often termed the Reindeer Period. Immense quantities of reindeer remains had been excavated from this particular level. The cave has been rich in remains of animals now extinct in Great Britain, including the cave lion, cave hyena, the mammoth, woolly rhinoceros, bison, horse, and several species of deer.

King's College, London

Work has now begun on the new anatomy department of King's College, which is being constructed in two additional stories on the roof of the existing buildings at a cost of over £60,000. Greatly increased laboratory, research, and museum accommodation will be provided. The anatomy department in future will be in close geographical association with the other biological departments of the College, and for their general use a suite of

rooms for animal experimental work is being included in the new building. These extensions represent the first step in execution of the building programme set out in the centenary appeal of the College. The next will be the conversion of the old anatomy department into an extension of the chemistry department. The extension and thorough modernization of the medical department of the College has been undertaken to meet the needs of the large and growing pre-clinical school, which is associated on the clinical side with four of the London teaching hospitals—King's College, Charing Cross, Westminster, and St. George's.

The Sound Film in Medical Education

Recently a party of about ninety-five members of King's College Medical Society, including Professor D. M. Blair, the dean of the Medical Faculty, were entertained to a sound film of a Caesarean section, by the courtesy of the Western Electric Company, Ltd., at their private cinema in Bush House. Mr. F. B. Ransford, on behalf of the company, made a short speech welcoming the society, and explaining the use that such a film could be put to for instructional purposes, not only for medical students, but for practitioners attending refresher courses. He advocated the use of cinemas constructed in hospitals and medical schools, and also facilities for taking sound films of any peculiar cases or operations, so that the latest hospital technique and instruction could be available for all doctors and surgeons throughout the country. At the conclusion of the film the dean spoke a few words, agreeing with Mr. Ransford, and pointing out the special advantages of this film, in that it could take the student away from the operation theatre and explain the subject more lucidly by means of animated diagrams, while none of the actual operation was missed; moreover, the various complications to the operation could be shown as a part of the same film. He also called attention to the method used in the film by Dr. De Lee, the operating surgeon of the Chicago Lying-in Hospital, who, it should be mentioned, used and recommended a local anaesthetic. Mr. J. D. Moore, the president, then proposed a hearty vote of thanks to the Western Electric Company and the honorary secretary of the Medical Society for the trouble taken in arranging the visit.

Coroners' Inquests

Addressing the jury at an inquest held recently by him at Southwark, Dr. Waldo said that the new permissive power given coroners under the Coroners (Amendment) Act, 1926, in cases of sudden death from causes unknown, of merely requesting the family doctor or any other medical man to make a post-mortem examination, and dispensing with a formal inquest, and then reporting to the local registrar the cause of death as suggested by the doctor, cast grave responsibility upon the coroner. Some experienced coroners, both medical and legal, had expressed the opinion that if a necropsy was necessary, a formal inquest, with the witnesses on oath and the relatives present, was equally necessary in the public interest. He (Dr. Waldo) noticed in the Criminal Statistics for 1929, just published, a considerable divergence and want of uniformity in the use of the new power given coroners under Section 21 of the Coroners Amendment Act. For instance, among whole-time coroners one coroner held 632 inquests during 1929, and, in the same year, as many as 604 non-inquest cases with post-mortem examinations only. Meanwhile other whole-time coroners had made no use whatever of Section 21 of the new Act. It would be both interesting and instructive to know the reasons for the diverse procedure of coroners under Section 21 of the new Act.

Ireland

Vital Statistics for Northern Ireland

During the first quarter of the present year 6,427 births were registered in Northern Ireland, and 5,814 deaths, of which 693 were of infants under 1 year of age. The population being estimated provisionally at 1,246,000, the mortality works out at 18.7 per 1,000, as compared with 18.6 in the Irish Free State, and 16.5 in England and Wales. Of the total deaths 1,229 occurred in public institutions, and 482 were uncertified. There was a diminution in all forms of infectious disease notified, especially scarlet fever, with the exception of acute pneumonia. Influenza was prevalent in all parts of Northern Ireland. The epidemic commenced about the second week in January, reached its peak in the first week of March, and then quickly receded. On the whole the epidemic was mild in character. Measles also has been epidemic in Belfast county borough; otherwise the health of the area is stated by the Chief Medical Officer of the Ministry of Home Affairs to have been fairly satisfactory during the quarter. The urban mortality from the principal epidemic diseases was equivalent to 1 per 1,000 of the population, the death rate from these diseases for the remainder of Northern Ireland being 0.3 per 1,000.

Hospital Services in County Armagh

At the last monthly meeting of the Committee of Management of Armagh County Infirmary a letter was read from the Northern Ministry of Home Affairs which had been addressed to the county council in answer to an inquiry if the Ministry had yet prepared a comprehensive scheme for the hospital service of the county. The occasion of the inquiry was the sanctioning of a loan of £40,000 by the Lurgan Board of Guardians for the improvement of hospital buildings in Lurgan and for the reconstruction of the workhouse hospital. The Ministry stated that the Government had not come to any decision with regard to the general reorganization of the local government services, but that it was satisfied that the continued existence of the workhouse infirmary at Lurgan was necessary, and that the present buildings required considerable alteration to make them suitable for their purpose. In the circumstances there appeared to be no alternative but to authorize the board of guardians to proceed with the reconstruction of the premises. A deputation, including members of the council, was appointed to discuss the matter further with the Ministry.

St. Ultain's Hospital

At the annual meeting of St. Ultain's Hospital, held recently, Miss Ffrench Mullen, secretary to the hospital, intimated that, with the prospect of a substantial cheque from the sweepstake scheme, work had already been begun on a new wing; the addition of four wards would help to reduce the waiting list and provide extra accommodation for nurses. In proposing the adoption of the report, Dr. Ella Webb declared that the importance of children's diseases was not sufficiently recognized in examination papers. Professor T. Gillman Moorhead, President of the Royal College of Physicians, stated that, while the infant mortality rate was falling in Ireland, it was still too high. The death rate in the Irish Free State was formerly 90 in every 1,000, but this had now fallen to 70, a figure that compared very favourably with the returns from the British Isles generally. Dr. Horne said that, although 95 per cent. of the sick babies treated were born in sound health, most of them were in a semi-moribund condition when admitted. The value of St. Ultain's Hospital could be realized by the fact that over a hundred of these babies were cured every year on an average, and given a good start in life.

Correspondence

OSTEOPATHY AT HOME AND ABROAD

SIR,—The Bill for the recognition of osteopathy and for conferring upon its exponents approximately the same legal status as is enjoyed by registered practitioners in medicine, which received its first reading just before the Parliamentary recess, has been withdrawn, owing, we are informed, to differences of opinion among the osteopaths themselves. Perhaps this happy consummation has been brought about through the realization, tardy but welcome, by the British osteopaths that their American colleagues in this country were using them to pull chestnuts out of the fire for the American colleges, which are no longer as prosperous as they used to be.

In the debate upon the motion brought forward by me in the House of Commons on February 9th, 1926, asking for "an inquiry into the whole position of irregular practice in medicine and surgery"—under which heading, of course, osteopathy figured prominently—Mr. Neville Chamberlain, the then Minister of Health, made a vitally important official pronouncement, which has served as a very effective check upon efforts on the part of various unqualified practitioners to secure recognition. Thus a few months after that date efforts by the opticians to obtain "registration" were frustrated by the quotation of that pronouncement. Mr. Neville Chamberlain said that "if the osteopaths wanted to have a register of osteopaths in this country, let them set up their own colleges, give their own diplomas, and then they would be forced to do what they had done in America; their curriculum would gradually have to conform to something very nearly approaching the normal curriculum in this country," and, with pointed reference to a claim that diplomas given by American colleges should be recognized in this country, he said that "to ask this country to accept diplomas from another country, into the value of which we really could not pretend to examine, and over the qualifications for which we have no control, is really not a practical proposition." Notwithstanding this warning, the promoters of the Bill which has just been withdrawn included a clause admitting to the proposed register "the holder of certificates granted in a British Dominion *or foreign country*" (the italics are mine), thus clearly foreshadowing the wholesale recognition of American diplomas, expressly deprecated by Mr. Chamberlain. Happily, as I have said, British osteopaths have recognized at last this impudent effort on the part of the American osteopaths to force their diplomas upon the osteopathic practitioners in this country, for that is what would necessarily have eventuated from the Bill. The British School of Osteopathy remains so inadequately equipped from every point of view to teach any branch of medical science that it does not fulfil the requirements mentioned by Mr. Chamberlain, and the Americans, who so largely dominate, and would continue to dominate, any osteopathic association in this country, would see to it that British students would be required to resort to American colleges before they were granted admission to the British Register of Osteopaths. It is doubtless that well-justified apprehension on the part of British osteopathic practitioners that has brought about the present collapse of the Bill.

In order to oppose the Bill more effectively when it should reach its second reading in the Commons, I communicated with the very efficient Bureau of Legal Medicine and Legislation of the American Medical Association, and I have received new information regarding the present position of osteopaths in the United States which may interest your readers. This information offers, I think, an explanation of the present drive by the American osteopaths in this country.

In the United States, the happy hunting ground of quacks of all kinds, osteopathy is only one of very numerous cults "recognized" in varying degree by the legislatures of the various States. It is difficult for us, but important, to realize that in the United States there is no general authority (in America it would be called "Federal"), such as is vested in our General Medical Council, to distinguish qualified from unqualified practitioners of medicine; consequently in every State conditions of admission to practice are peculiar to that State. It is exceedingly difficult, therefore, to form a general view of the measure of recognition offered in the States to osteopaths, but there are certain recent tendencies which are acting in the direction of making osteopaths particularly anxious to assimilate their practice to that of orthodox medicine; indeed, it might be said that the original and demonstrably absurd formula of its founder, Andrew Still, upon which osteopathy pretended to base any claims it has for distinctive medical practice, is now much less rigidly followed by osteopaths than by their imitators the chiropractors, who are also widely recognized in the United States. Mr. Chamberlain's acute prophecy in 1926, that the curriculum of the osteopaths would more and more conform to the curriculum of general medicine, has become justified by the event; thus, in a very illuminating report sent to me by the secretary of the Michigan State Medical Society's legislative department, as the result of an inspection of the Philadelphia College of Osteopathy carried out in 1930 by the secretary of the Michigan State Medical Society, Dr. Warnshuis, it is stated that "the Philadelphia College has been established about thirty-five years, and is accepted by osteopaths as their best college. . . . All branches of medicine were represented, such as the Cardiac Clinic, Eye, Ear, Nose and Throat, Genito-Urinary, Gastro-Enterology, etc.," and the significant note is added that "in connexion with the out-patient department there was a large pharmacy, the shelves being well filled with all types of drugs." Dr. Warnshuis, while conceding that "the approach to the conditions of the orthodox medical colleges made by the Philadelphia School is thus very considerable," and that "the younger element, at any rate, which is rapidly assuming control, would probably welcome a working agreement with the colleges of medicine, and even an absorption by the Association of Medical Colleges if a chair of mechano-therapeutics can be established at those colleges," notes that the weak point in osteopathic training is the poor teaching personnel, especially in the medical sciences and in clinical medicine—a weakness obvious in all the "approved" osteopathic schools.

Another movement acting with the same effect is the increasing insistence in the United States upon a certain level of teaching in what are called the "basic sciences of medicine"—anatomy, physiology, chemistry, bacteriology, pathology (and in some States hygiene)—a level to which any cult aspiring to any kind of medical practice must conform. The passage of laws requiring this level of preliminary scientific education in many States has resulted in reducing enormously the number of osteopathic and other "cult" candidates, and osteopathic schools which have not raised their standards to this level have largely gone out of practice, so that there are now not thirteen, but only six, "approved" osteopathic schools. Some of these competing cults—chiropractic, naturapathy, sanipractic, naprapathy—have trespassed so far upon the domain of osteopathy as to diminish what one of my correspondents calls "the pulling power of osteopathy as a novelty," and it is, of course, the similar

competition in this country that has made osteopaths here so anxious for registration.

That the osteopathic calling in America has felt the draught is obvious from a "message" from the president of the American Osteopathic Association, conveyed in the journal of that association for August, 1930, in which he says: "If osteopathy is to live, our colleges must have more students," and one of the devices which he recommends for attracting students is the exhibition of a picture called "Dan's Decision," in which it is naïvely stated that the American Osteopathic Association "has invested 8,500 dollars," and which it earnestly entreats its members "to exhibit in every town and city." In other words, while the medical schools of the United States are picking and choosing their students from a much larger number of qualified applicants for admission than the schools can accommodate, the osteopathic schools are touting for new recruits by using the methods of the cheapjack. In this situation of a falling home consumption one may perhaps find the explanation of the recent attempt to capture for American osteopaths the British market, an attempt which, for the moment at any rate, has failed.—I am, etc.,

London, W., May 30th. E. GRAHAM-LITTLE.

OPERATION FOR CATARACT

SIR,—In your issue of May 16th (p. 877) a reference is made to cataract and medical practice, which raises points of practical interest.

It is stated that the sight of the one eye is "very good." This raises the question whether an operation for cataract in one eye, when the vision of the other is sufficiently good to enable the patient to carry on his work, is advisable or justifiable. The important point is: Will the patient be benefited?

As Mr. Bishop Harman has pointed out, the patient will continue to use the unoperated eye as he has done before the operation. The late Professor Schmidt-Rimpler of Halle discussed this question fully on the basis of his own personal experience (*Klinische Monatsblätter für Augenheilkunde*, 1911, Bd. 49, S.692). He states definitely: "I therefore advise no one, who has a healthy eye with normal vision, to permit a cataract to be removed from the other eye unless there are special reasons. . . ." This has always been my own practice, and on the several occasions on which I have deviated from it, at the patient's request and after giving due warning, I have always found that the patient was very uncomfortable, even when the vision of the better eye was considerably impaired, so that it was necessary to use an opaque glass before it, or that, alternatively, he did not make use of the operated eye. In one case the patient insisted on using the unoperated eye, although the operated eye, with its cataract lens, had better vision, and it was necessary to remove the immature cataract from the unoperated eye. Fortunately, the intracapsular method successfully overcomes any difficulty in this respect. The question is of interest in as far as patients, and sometimes doctors, have some difficulty in understanding why unilocular cataract cannot simply be removed with restoration of normal vision.

The second question arises from the sentence "Of course he understands that anyhow he will not be able to drive his car." A patient with cataract in one eye who can drive a car before operation can surely drive it afterwards, using either the operated eye with a lens, or the unoperated eye. My experience is that patients can drive cars and shoot pheasants after operation on one eye.

A third point which arises indirectly is: If a patient has had a successful operation on one eye, is any material advantage gained by operating on the other commensurate with the risks involved, especially in old persons, the expense, etc.? This question, again, will be decided differently according to circumstances, but as a general rule the answer is in the negative.—I am, etc.,

Edinburgh, May 26th. H. M. TRAQUAIR.

FRACTURES OF THE NECK OF THE FEMUR

SIR,—In answer to your correspondent C. S. (May 23rd, p. 913) may I say that the typical deformity in fractures of the neck of the femur is adduction? The angle formed between the neck and shaft is less than normal, excepting in rare cases. The greater the shortening the more the adduction; and in old neglected cases with a real shortening of an inch it is not uncommon to have a practical shortening of three inches or more, due to a combination of flexion and adduction.—I am, etc.,

Liverpool, May 26th. ROBERT JONES.

SIR,—Sir Robert Jones, in his article on fractures of the neck of the femur, states that the correct technique of the plaster-of-Paris spica is too often ignored, though this must be mastered for the splint to be comfortable and efficient. Will some one familiar with the approved method describe it in detail in your columns, and will he indicate the best way to remove the splint when it is no longer required?—I am, etc.,

Ludlow, Salop, May 28th. T. H.

TREATMENT OF BRAIN ABSCESS

SIR,—In his interesting and successful case of otitic cerebellar abscess described in the *Journal* of May 23rd, Mr. Courtenay Yorke emphasizes: (1) the use of the hypodermic syringe in the exploration for brain abscess; and (2) the use of a drain of small size and with the object of drainage alongside and not necessarily through the tube. In the *Proceedings* of the Otological Section of the Royal Society of Medicine I have taken the opportunity on more than one occasion to support this view, in fact so far as to express enthusiasm for it.

Syringe and needle exploration appears to be particularly reliable in the discovery of otitic brain abscess either of the cerebellum or of the tempoto-sphenoidal lobe. If the findings are negative then there is either no brain abscess or it is out of reach, or has not been entered by the needle. Lund has emphasized the value of the method, and if a healthy brain be punctured in a negative case no apparent harm results. This writer also favours the small drain, and refers to the work of Lemaître, who has advocated filiforms for the purpose. It is unnecessary to make a greater opening in the dura mater than will suffice to admit the drain.

Success in the treatment of brain abscess may lie with its early recognition, and a reliable method of exploration and drainage will encourage otologists to take action, particularly if the trauma caused may be reduced to the minimum.—I am, etc.,

Liverpool, May 28th. H. V. FORSTER.

PSEUDO-ARGYLL ROBERTSON PUPILS WITH ABSENT TENDON REFLEXES

SIR,—In Dr. W. J. Adie's interesting paper under the above heading (*British Medical Journal*, May 30th, p. 928) no allusion is made to the first account of such cases published in England—namely, that by Dr. C. Markus, "A peculiar pupil phenomenon in cases of partial iridoplegia," in the *Ophthalmological Society's Transactions* (1906, vol. xxvi, p. 50). In Dr. Markus's first patient he mentions that, in addition to absence of knee-jerks, I

found absence of Achilles reflexes. But surely Dr. Adie does not mean to separate cases presenting what might be termed " atypical (generally unilateral) Argyll Robertson *large* pupil with ' hypertonic ' reaction to accomodation," *without abnormality of tendon reflexes,* as of different nature from cases similar in regard to the pupil phenomena, but *with absent tendon reflexes.* Dr. Markus alluded to the question of syphilis, but favoured the view that the condition might be regarded as the result of an " abiotrophy " in Sir William Gowers's sense. Dr. Markus's observations on the relative parts played by accommodation and convergence in producing pupil contraction have apparently not received much attention.

Incidentally, in regard to the insidious onset of the pupil phenomena in many similar cases, I may mention that the subject of Dr. Markus's third observation was a fellow-student with me at Trinity College, Cambridge, where I used to see him almost every day, and can therefore say that he almost certainly did not then have unequal pupils. As to prognosis in such cases, it is interesting that since Dr. Markus's paper this doctor (his third case) overcame a severe attack of typhus exanthematicus, and scientifically has greatly distinguished himself. It seems, therefore, unlikely that, except for the purely local condition, the prognosis can be bad.—I am, etc.,

London, W., May 30th. F. PARKES WEBER.

RUPTURE OF TENDONS

SIR,—In Mr. Harry Platt's interesting paper on rupture of tendons, published in the *Journal* of April 11th, I was struck by the brevity of his reference to the injury popularly described as " rupture of the plantaris tendon." He dismisses it as an incorrect diagnosis for partial rupture at the musculo-tendinous junction of the tendo Achillis. His view is supported by the fact that in cases where he has operated for rupture of the tendo Achillis he has found the plantaris intact.

It would be interesting to know whether a rupture of the plantaris tendon has ever been demonstrated by operation, as the condition sometimes called " tennis leg " has several very distinctive features. First, it is very common—I have met with at least four while playing in tennis tournaments. Secondly, its symptoms are always typical—the patient looks round to see who has struck his calf. Thirdly, though very painful at first, it is quite possible to walk, and even run, if the foot is kept in a position of active plantar flexion, showing that tension on the damaged structure can be relieved by contraction of the muscles attached to the tendo Achillis. Finally, the most rapid cure results from getting the patient to start walking freely the day after the accident. I have suffered from the injury myself, and can vouch for the success of this somewhat painful treatment.

It would be interesting to know whether, in cases of partial rupture of other muscles in the body, relief can be obtained by active contraction of the undamaged portions of the same muscle, and rapid cure effected by its active exercise.—I am, etc.,

C. M. FINNY, F.R.C.S.,
Poona, India, May 14th. Major R.A.M.C.

CONVULSIONS DURING SURGICAL ANAESTHESIA

SIR,—Again the question of convulsions during anaesthesia has been raised in your columns, by Dr. J. Ross Mackenzie (March 14th, p. 440). He attributes the convulsions to two factors, toxaemia and ether, and mentions that in his cases convulsions did not occur for at least fifteen minutes. But cases have occurred with anaesthetics other than ether, and quite a number during induction. One of my own cases occurred during induction by chloroform alone in a dentist's chair. I had no hesitation in continuing the induction, and the patient took it well. He had not previously had fits, nor has he had any since.

I feel fairly confident that the great increase of convulsions under anaesthesia in recent years is due to the lightness of the anaesthesia rather than to the particular anaesthetic used. The proneness to convulsions is, of course, bound up with the greater tendency of some individuals to fits from slight provocation as compared with others, a subject of special importance in relation to epilepsy.—I am, etc.,

Melbourne, April 21st. W. SPALDING LAURIE, M.D., B.S.

ALKALINE THERAPY IN SCARLET FEVER

SIR,—In view of the work which has been done during the past three or four years for the prevention and treatment of albuminuria and nephritis in scarlet fever the following results may prove interesting in support of alkaline therapy. This method of medication, dating back to the end of last century, has received fresh impetus from the researches of Dr. A. A. Osman, and his work has proved so satisfactory that I attempted to adopt his theories in records of my own.

In all, I dealt with 589 cases of proved scarlatinal infection in patients from the age of 5 years and upwards admitted to three wards in Plaistow Fever Hospital, London. Out of that number only 11 developed albuminuria and 9 nephritis. The percentage of albuminurias, therefore, was 1.9, and the percentage of nephritis 1.5. This gives a total incidence of 3.4 per cent. Control cases gave a total incidence of 11.2 per cent., so the marked reduction indicates that alkaline therapy is of value in the prevention of these complications. The statistics of albuminuria were separated from those of nephritis—that is to say, cases with albumin only in the urine were distinguished from those showing blood and albumin.

The mixture used throughout the tests consisted of 40 grains each of potassium citrate and potassium bicarbonate to one ounce of water, and an ounce dose was given night and morning. There has apparently been some difficulty in the past in arriving at a satisfactory dose for administration, and, moreover, doubt has existed as to when the alkaline mixture should be commenced. In order to determine a satisfactory standard of dosage I further examined 63 cases of scarlet fever in the different weeks of illness. In those cases the drug was given in increasing doses until the urine recorded an alkaline reaction, and the transition from acid to alkali was determined more accurately by an estimation of the hydrogen-ion concentration of the urine. It was found as a result of those tests that the average dose of mist. alk. required to give an alkaline urine in first-week cases was 2 drachms three times a day for six doses ; for second-week cases 4 drachms three times a day for six doses ; and for third-week cases 4 drachms three times a day for nine doses. My cases in the fourth week of illness were too few to offer any conclusions, but it appears that the dose required in the fourth week would be 2 drachms three times a day for three doses. I am indebted to Dr. D. MacIntyre, medical superintendent of Plaistow Fever Hospital, for permission to publish my results.

These findings indicate that, as infection progresses, a larger dose of mist. alk. is required to render the urine alkaline ; in other words, that acidosis increases as time goes on. Now the period of maximum acidosis, or maximum alkali tolerance, appears to be in the third week of illness, and it is just at this time that nephritis usually shows, so a positive correlation does seem to exist between those two conditions. I would suggest from those results that, on admission, every case of scarlet fever in the first week—and most cases are admitted during that week—receive 2 drachms of mist. alk. three times

a day for two days; this should be sufficient to combat acidosis in this week. During the second week the dose should be increased to 4 drachms, and this could be maintained during the third week. Only by dealing with acidosis at the very commencement can we hope to prevent the cases of albuminuria and nephritis, which are still in large enough numbers (11.2 per cent. in my series) to cause concern to those responsible for their care.—I am, etc.,

Dewsbury, May 25th. JAMES B. SAMSON, M.D.

THE MODERN CONCEPTION OF EARLY PHTHISIS

SIR,—In reading over Dr. Camac Wilkinson's criticism of Dr. Morlock's observations on early phthisis, in your issue of May 9th (p. 818), I find that Dr. Wilkinson apparently places but small reliance on the *x*-ray appearances, and warns "general practitioners not to accept the teaching that *x*-ray examinations are the 'be-all and end-all' either in diagnosis or in treatment." He states also that: "We dare not trust implicitly to *x*-ray shadows in laying the foundation of a new theory. . . . Certainly *x*-ray shadows should never displace pathological anatomy or a thorough physical examination."

It would seem to me that the radiographic appearances would form an ideal method of studying pathological anatomy, pre-eminently in diseases of the lungs; and that an opinion on the condition of the chest given by a radiologist who is an expert in such examinations, and who at the time when his report is made has no knowledge of the clinical findings, offers a chance of arriving at the correct diagnosis which is not at the moment equalled by any other method. It is understood that at the present time radiographic methods have reached such perfection that the diagnosis is made by actually observing the tubercles in the lung parenchyma. But let the radiologist realize that it is often quite impossible to estimate the degree of activity of the lesion without the aid of serial radiography over a period of months. The diagnosis of phthisis is made by observing the presence of tubercles and certain types of cavity formation, and special care is always taken not to call opacities which do not exhibit these features phthisis. In those rare cases where a positive sputum is discovered and there is an absence of *x*-ray changes in the lung, one finds that the physician will always have further sputum examinations and a second radiographic examination made, to confirm.

We are all working together with a common object in view—the diagnosis of disease—and any method which will lead to the earlier recognition of phthisis should be followed up; but do not let it be thought that there is any doubt about the position of radiology in assisting in the diagnosis of pulmonary disease.—I am, etc.,

London, W.1, May 28th. J. V. SPARKS.

MICROCEPHALY

SIR,—In his very valuable survey of the present knowledge of cortical structure in relation to mental disease, Professor R. J. A. Berry (*British Medical Journal*, May 16th) uses the word "microcephaly" as though, apparently, he regards it as synonymous with the smallness of brain that is common in most aments. I think, from other of his writings, that this is his view. It is, however, usually taught that microcephaly is a very definite condition marking one of the types of mental deficiency, and that its character depends far more on shape than on size of head. If some authorities use the word in the general sense and others in the particular, we are left in confusion, and misunderstanding is the result. How can the difficulty be overcome?—I am, etc.,

London, S.W.17, May 27th. NOEL H. M. BURKE.

PITUITRIN AND OBSTETRIC SHOCK

SIR,—The letter in the *Journal* of May 30th (p. 955) over the signature of Dr. Peter McEwan suggests that so-called pituitary shock may be due to an idiosyncrasy on the part of the patient. It would be interesting to know whether fluids had been withheld from the patient for any considerable time before the pituitary extract was administered, because investigation of one or two similar cases recently has indicated that a depletion of body fluids may be the predisposing factor leading to pituitary shock. If this is the correct explanation it would suggest that posterior pituitary extract, in which the pressor, antidiuretic, and oxytocic principles are all represented, should not be given to a patient in a dehydrated condition, but that pitocin, the separated oxytocic principle, should be employed in preference.

Dr. McEwan uses the word "pituitrin," presumably in a generic sense, but actually "pituitrin" is applied solely to the posterior pituitary extract as first offered to the medical profession by Parke, Davis and Co. The use of the word "pituitrin" to refer to posterior pituitary extracts in general is particularly unfortunate, in view of Dr. McEwan's statement that "pituitrin used to vary notably in strength." For many years prior to the introduction of the Therapeutic Substances Act "pituitrin" was standardized on both its oxytocic and pressor values, and the strength of the solution has always been remarkably constant. In fact, the strength adopted all along for "pituitrin" is precisely the same in respect of oxytocic action as that which is now the obligatory standard in the regulations under the above-mentioned Act, which requires all posterior pituitary extracts to be of uniform potency in respect of oxytocic value only.

It is noted that in the case referred to by your correspondent the pituitary extract was given in doses of 1 c.cm.—a total of 3 c.cm. in five and a half hours. This dose would surely seem to be excessive, because in the light of the work of Bourne and Burn it is now generally agreed that the optimum dose for obstetrics is two to three units (0.2 to 0.3 c.cm.), and this dose should seldom be exceeded. In the treatment of post-partum haemorrhage a dose of 0.5 c.cm. or even 1 c.cm. may be permissible.—We are, etc.,

London, W., June 1st. PARKE, DAVIS AND CO.

EXAMINATION OF MOTORISTS CHARGED WITH DRUNKENNESS

SIR,—Insensibility of a motorist—as in the case referred to by Dr. Brooks Keith in his letter in to-day's *Journal*—one would think was a condition sufficiently serious to justify the police calling in medical aid, even for the following purposes only:

1. To verify that the unconsciousness was in fact due to alcohol and not to other causes—illness, etc.
2. To decide whether the person was physically fit to be detained in a police cell.

These are not such simple matters as can safely be left for a non-medical person to decide. Experience as a police surgeon has afforded me several instances of so-called "obvious drunkenness," which medical examination showed to be due to causes other than alcoholic intoxication. In such cases it is due to the public, as well as to the arrested individual, that the diagnosis should be put beyond a doubt—essentially a doctor's job. Fortunately, in this country the judges at trials do require such medical evidence. Otherwise there might be still more wrongful convictions—to say nothing of the cases of "drunk or dying."—I am, etc.,

London, S.E.11, May 30th. REES PHILLIPS, M.D.

BIRTHDAY HONOURS

The Honours List, issued on June 3rd, on the occasion of His Majesty's birthday, includes the names of the following members of the medical profession.

K.C.V.O.

Major-General Sir S. GUISE-MOORES, K.C.B., C.M.G., House Governor and Medical Superintendent, Osborne Convalescent Home for Officers.

Knights Bachelor

PENDRILL CHARLES VARRIER-JONES, M.A., M.R.C.P., M.R.C.S., Founder and Medical Director of Papworth Village Settlement for the Treatment of Tuberculosis.

Colonel SAMUEL RICKARD CHRISTOPHERS, C.I.E., M.B., F.R.S., I.M.S. (ret.), Director, Central Research Institute, Kasauli.

Lieut.-Colonel HENRY ALBERT JOHN GIDNEY, F.R.C.S.Ed., I.M.S. (ret.).

C.B. (Military)

Surgeon Rear-Admiral ALFRED J. HEWITT, C.B.E.

Major-General WILLIAM R. BLACKWELL, C.M.G. (late R.A.M.C.), K.H.S., Deputy Director-General A.M.S., War Office.

Major-General JAMES D. GRAHAM, C.I.E., M.B., I.M.S., K.H.S., Public Health Commissioner, India.

C.M.G.

WILLIAM N. ROBERTSON, C.B.E., M.B., Vice-Chancellor, University of Queensland.

C.B.E. (Military)

Wing Commander WILLIAM W. SHORTEN, F.R.C.S.Ed., R.A.F.

C.B.E. (Civil)

ALBERT L. HOOPS, M.D., Principal C.M.O., Straits Settlements.

ARTHUR H. NORRIS, *M.C.*, M.R.C.S., L.R.C.P., D.P.H., Chief Inspector of Reformatory and Industrial Schools, Home Office.

O.B.E. (Military)

Lieut.-Colonel CHARLES J. COPPINGER, R.A.M.C.

O.B.E. (Civil)

FREDERICK W. ALEXANDER, M.R.C.S., D.P.H., formerly M.O.H. for Bromley and Poplar Districts.

ERIC DENHOLM PRIDIE, D.S.O., Medical Inspector, Sudan Medical Service.

ALFRED C. NORMAN, M.D., Director of the *X*-ray and Electrical Institute, Baghdad, Iraq.

M.B.E. (Military)

Lieutenant (Senior Assistant Surgeon) A. N. DE GRUYTHER, I.M.D.

Lieutenant (Senior Assistant Surgeon) JAMES BERCHMANS D'SOUZA, I.M.D.

First Class Assistant Surgeon RICHARD C. GALE, I.M.S. (attached Iraq Levies).

M.B.E. (Civil)

SHIVRAM WAMANJI PATIL, medical practitioner, Bombay.

JOCELYN MAINGARD, medical officer, Mauritius, for services in the relief of sufferers from the recent hurricane.

ROGER PILOT, Medical Officer, Mauritius, for services in the relief of sufferers from the recent hurricane.

Honorary M.B.E. (Civil Division)

ZAHI HADDAD, M.O.H., Haifa, Palestine.

Kaisar-i-Hind Medal (Bar)

HENRY T. HOLLAND, C.I.E., M.B., F.R.C.S., C.M.S., Quetta, Baluchistan.

Kaisar-i-Hind Medal (First Class)

Miss HILDA KEANE, M.D., Medical Superintendent, Victoria Zenana Hospital, Delhi.

Miss ADELAIDE WOODIARD, Doctor in Charge, American Presbyterian Memorial Hospital, Fatehgarh, U.P.

IAN ROSS ANDERSON, M.O. in charge, Kalna Mission Hospital of United Scottish Churches Mission, Bengal.

Imperial Service Order (Companions)

Major E. F. HOTTINGER, L.M.S.S.A., I.M.D., Civil Surgeon, Punjab.

LORENS ARTHUR PRINS, Inspecting Medical Officer, Ceylon.

The Order of Merit is conferred upon Sir WILLIAM HENRY BRAGG, K.B.E., F.R.S., in recognition of his eminent services to the advancement of science.

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

The House of Commons reassembled on June 2nd, when the third reading of the Representation of the People Bill was taken. Scottish Estimates were put down for the following day, and a Probation of Offenders (Scotland) Bill for June 5th. During the week the House was asked to approve a time-table for the coming debates on the Finance Bill. The House of Lords had no business this week.

On June 2nd Lord Astor addressed the Liberal Parliamentary Party on the grading of milk.

Infant Mortality in India

On June 2nd Mr. BENN, replying to a question, said that figures of the infantile death rate in the cities of Bombay and Madras for 1930 were not available. In 1929 the infantile death rate (under 1 year) in Bombay city was 300.66 per 1,000 registered births. Of the deaths of infants, about 3.3 per cent. were registered as due to small-pox. In the same year in Madras city the infantile death rate was 259.2 per 1,000 registered births. In 1929, 503 deaths from small-pox (about 8.4 per cent. of the total deaths) were registered, but details as to how many were those of infants were not available. The epidemic was the severest since 1905, with the exception of 1924.

Mr. BENN, on June 2nd, informed Mr. Freeman that no exact figure could be given of the average age of mortality in British India. In 1928 (the latest year for which materials for calculating were available) the average age was about 23 years.

Mr. BENN stated that in 1929-30 the gross expenditure of British India (Central and Provincial) on medical and public health services was 6,61,95,450 rupees. This was 2.9 per cent. of the gross revenue for the year.

Universities and Colleges

SOCIETY OF APOTHECARIES OF LONDON

The following candidates have passed in the subjects indicated:

SURGERY.—T. F. Davies, O. L. Matthews, C. F. Vieyra, V. M. White.

MEDICINE.—T. F. Davies, B. N. Halder, T. L. O'C. Ryan.

FORENSIC MEDICINE.—G. I. Benjamin, A. N. Coondoo, T. F. Davies, B. N. Halder, A. E. Mathews, S. Ramarao, L. B. Reeves, D. N. Ryalls, H. W. Toussaint, M. R. Tuteur-Samuel.

MIDWIFERY.—M. Belo-Zercovsky, T. F. Davies, W. B. Mattar, T. L. O'C. Ryan, M. R. Tuteur-Samuel, C. F. Williamson.

The diploma of the Society has been granted to Messrs. G. I. Benjamin, T. F. Davies, and A. E. Mathews.

The Services

TERRITORIAL DECORATION

The Territorial Decoration has been conferred upon Lieut.-Colonel G. L. Leathes Lawson, R.A.M.C.(T.F.) (ret.), under the terms of the Royal Warrant of October 13th, 1930.

INDIAN MEDICAL SERVICE DINNER

The annual dinner of the Indian Medical Service will be held at the Trocadero Restaurant on Wednesday, June 17th. Colonel R. A. Needham, C.I.E., D.S.O., has been invited to take the chair. Tickets and all particulars may be obtained from the joint honorary secretary, Major Sir Thomas Carey Evans, *M.C.*, I.M.S. (ret.), 31, Wimpole Street, W.1.

Obituary

SIR HERBERT WATERHOUSE, M.D., F.R.C.S.

Consulting Surgeon, Charing Cross Hospital; President, Medical Defence Union

As announced in our last issue, Sir Herbert Waterhouse, for many years surgeon to Charing Cross Hospital, died suddenly at his residence in Wimpole Street on May 23rd. About a year ago he had a serious accident, being knocked down by a motor car which mounted the pavement in Harley Street; he was unconscious for several days, but after his recovery continued to take an active part in the work of the Medical Defence Union, of which he was president.

Herbert Fretwell Waterhouse was born in London in 1864, and studied medicine in the University of Edinburgh, where he won the Goodsir Memorial Prize and the Dalgety Travelling Fellowship. He graduated M.B., C.M. with honours in 1887, and was awarded a gold medal for his M.D. thesis in 1888. In 1890 he obtained the Fellowship of the Royal College of Surgeons of England. Before leaving Edinburgh he had held office as president of the Royal Medical Society, and served as resident surgeon at the Royal Infirmary. A period of post-graduate study at Göttingen was followed by appointment as resident surgeon at the Glasgow Royal Infirmary. Then, in 1890, Waterhouse came to London and began his long association with Charing Cross Hospital, to which detailed reference is made below. Later he was appointed surgeon to the Victoria Hospital for Children, Chelsea, to the Osborne Home for Officers, and to the Kensington Children's Hospital. For many years he was examiner in surgery for the Universities of London, Manchester, Birmingham, and Liverpool. He was also a member of the Court of Examiners of the Royal College of Surgeons of England from 1909 to 1919, and served on the Council from 1915 to 1920. He was the author of articles on diseases of the mouth, palate, tongue, tonsils, and pharynx in Treves's *System of Surgery*, and on affections of the nose, larynx, and œsophagus, and other diseases, in Quain's *Dictionary of Medicine*. In recognition of his war services as surgeon-in-chief of the Anglo-Russian Hospitals in Petrograd the honour of knighthood in 1917. Lady Waterhouse died a year or two ago, and he is survived by two daughters.

Sir Herbert Waterhouse was for many years a member of the British Medical Association, and filled the offices of secretary and president respectively of the Section of Diseases of Children when the Association held its Annual Meeting in London in 1895, and in Glasgow in 1909.

Mr. ERIC A. CROOK, dean of the Medical School of Charing Cross Hospital, writes:

The loss of Sir Herbert Waterhouse is one which will be felt by all those who have known him, and most especially by those who have been associated with him at Charing Cross. It was forty-one years ago that he was appointed lecturer in anatomy, joining the hospital after a distinguished student career at Edinburgh University, where he obtained the gold medal in the examination for the degree of Doctor of Medicine, and distinction in that of Master of Surgery. In 1891 he was elected assistant surgeon to Charing Cross Hospital, and in 1903, on the retirement of Mr. Bloxam, he became surgeon to the hospital. He was dean for five years (1901–6), a period of great progress in the Medical School, which was attributable in no small measure to the enthusiasm and zeal that he showed in every sphere of his life. He held the respect and affection of those working under his direction, and was always ready to give help and advice in difficulties that were taken to him. His guidance was always helpful, but his directions had invariably to be put into action without delay. His kindness was best shown by the great personal interest which he took in those students who worked directly under him, and it was his proudest boast that three of his house-surgeons were subsequently elected to the staff of the hospital — Stephen Fenwick, Norman Lake, and Jennings Marshall. As a teacher Sir Herbert's methods were essentially practical, and were dramatically illustrated. He was an advocate of study at the Continental universities as an important part of professional education. During his time as dean of the Medical School, Professor Pavlow, Professor William Welch, and Sir William Macewen were invited to deliver the Huxley Lectures. He was elected a member of the Council of the Royal College of Surgeons in 1915, and served his full term of eight years. He was also an examiner in anatomy and surgery at this time. As an operator and clinician his outstanding abilities are universally known, and need no further comment. In his work outside the hospital, he took very great interest in the Clinical Section of the Royal Society of Medicine, and it will always be remembered how, during his presidency, he raised this Section from its lowest ebb to its present prominent position. Since his retirement from the active staff of Charing Cross Hospital some seven years ago, he has given his valuable services as a member of the council.

Dr. JAMES NEAL, General Secretary of the Medical Defence Union, writes:

By the death of Sir Herbert Waterhouse the Medical Defence Union has sustained a very severe loss. From the time he was elected a member of the Council, in February, 1922, he always took a keen interest in t

work of the Union, and when he became President, in October, 1925, he devoted himself with great enthusiasm to the duties of his office. He was much more than a figurehead; he made it his business to master the details of every difficult case, and spared no effort to safeguard the interests of our members and to repel unjust attacks upon them. Although a busy man, whose time was still largely occupied by professional work, Sir Herbert was always ready to give his close attention to the affairs of the Union. No matter how difficult the problem to be faced, he could always be relied upon to take a broad and statesmanlike view of the available evidence, and his wide experience in medico-legal problems, his sound judgement, and his shrewd common sense greatly assisted the Council to arrive at wise decisions, to the great benefit of our members. His interest in the work never flagged, and by his invariable courtesy, his conspicuous fairness, and his unfailing good temper, he gained the confidence of all he came in contact with, and earned the esteem and affection of his colleagues on the Council. Sir Herbert had the happy knack of combining the *suaviter in modo* with the *fortiter in re*, and he possessed those other personal qualifications which make the ideal president. His valuable services cannot be overestimated, though his work was largely done behind the scenes, and was known only to a few. He will be greatly missed.

[The photograph reproduced is by Thomas Fall, London.]

THE LATE PROFESSOR HALLIBURTON

We are indebted to Sir FREDERICK HOPKINS (President of the Royal Society) for the following appreciation:

To know that Halliburton is with us no more is to feel a sad break with the past, and to be sensible of a gap, no less sad, in one's intellectual environment. Ill-health had kept him out of the arena for some years, but to the last one could reckon on his interest in the things there done. When perforce he went out of the game he remained one of those whose approval makes the continuance of the game worth while. It seemed part of the established order of things that he should be there to approve when approval was earned.

The progress of biochemistry was always dear to Halliburton; we who have been his contemporaries, but have been allowed to outlive him, welcome our younger colleagues, and recognize how much more they know than we knew in our youth; but we sadly miss converse with those who remember past struggles. Halliburton himself began to contribute to knowledge when young enough. He was doing good original work when but little more than twenty, and when his mind was not yet free from the inhibitions wrought by examinations. He took a science degree when eighteen, and qualified at two-and-twenty. Yet in the following year he combined the acquisition of the M.D. with the communication of excellent original work to the Physiological Society. The remarkable industry thus displayed was characteristic of his whole career. One wonders, indeed, if "industry" is quite the right word. He had a *flair* for doing good and continuous work without apparent effort. This was especially evident in his literary activities. It was refreshing, for instance, to note the seeming ease with which he abstracted current literature from the journals—a troublesome task which he often undertook to spare others the trouble. Odd moments, the vacant quarters of an hour, so often wasted, would with him contribute to the production of adequate abstracts from lengthy papers. So with the books he wrote or edited: the work he put into them, always finished at the appointed time, seemed to his friends to be effortless. If, however, Art may conceal Art, there is perhaps an effort which conceals effort. If so, as in the former case, it is genius.

It must always be remembered that Halliburton was, in the fullest sense of the word, a pioneer. It may be that at first he turned to the chemical side of physiology because its manipulations were more possible than those of some other sides for one who could use his right hand but little. Yet he quickly made this branch of science his own, and was the first in this country, by his work and writings, to secure for it general recognition and respect. Like all pioneers, he had at first to be content with poor equipment for the work he wished to do.

To speak of Halliburton without reference to his gifts of true friendship and generous sympathy is impossible. He was wholly free from small motives, and rejoiced in the success of others, whether pupils or friends. I, myself, though in years no younger than he, was a laggard in science. When I started I owed much to the stimulus of his approval. It is sad to feel that I cannot try to win it once more.

DR. ALFRED JOHN SEPTIMUS ROE died at his home in Beverley Road, Hull, on May 16th, after a long and painful illness. He was born at Plymouth in 1864, and, after studying at the School of the Royal College of Surgeons in Ireland, qualified L.R.C.S.I. in 1884 and L.R.C.P.I. in 1886. After a short time in Durham he went to Hull as resident surgeon to the Hull and Sculcoates Dispensary. He was later in general practice at Hull, giving it up about twenty-five years ago to specialize in diseases of the ear, nose, and throat. He was appointed honorary aural surgeon and laryngologist to the Dispensary. The founding of this department of the institution was due to his pioneer efforts. Of a quiet and retiring disposition, Dr. Roe, though keenly interested in national and medical politics, took no active part in them. He was a member of the British Medical Association. His only son died during the war.

Medical News

The summer dinner of the Australian and New Zealand Medical Association in England will be held at the Trocadero Restaurant, Piccadilly, on Friday, June 12th, at 8 p.m., with Mr. T. P. Dunhill, C.M.G., in the chair. Dr. F. N. Kay Menzies will be present as the official guest of the association. All medical visitors from Australia and New Zealand, whether members of the association or not, are invited to be present. The honorary secretaries are Mr. E. T. C. Milligan and Mr. Philip J. Jory, 26, Queen Anne Street, W.1 (Langham 1579).

The opening meeting of the centenary celebrations of the Harveian Society of London will be held at St. Bartholomew's Hospital on Thursday, June 11th, at 3 p.m., with the president, Sir Thomas Horder, in the chair, when Dr. Raymond Crawfurd will deliver an oration. On Friday, June 12th, the Buckston Browne dinner will be held at the Grocers' Hall, Prince's Street, E.C., at 8 p.m., and on Saturday, June 13th, a pilgrimage will be made to Hempstead Church, Essex, where the Bishop of Colchester will deliver an address at 12 noon.

The annual provincial meeting of the Section of Surgery of the Royal Society of Medicine will be held at the Manchester Royal Infirmary on Wednesday, June 10th. The train will leave Euston Station at 10.30 a.m., arriving at Manchester at 2.10 p.m. Operating sessions will be held from 2.30 to 4.30 p.m., and at 4.45 p.m. cases and specimens will be shown. The return journey will be by the train leaving Manchester at 6.20 p.m.

The sixth annual MacAlister Lecture will be delivered before the London Clinical Society at the London Temperance Hospital on Tuesday, June 16th, at 9 p.m., by Major Richard Rigg, chairman of the hospital. The subject is "Medicine and the city guilds." All medical practitioners are invited to be present, and may bring friends (ladies or gentlemen).

The annual meeting of governors of Epsom College will be held at the Royal College of Physicians, Pall Mall East, S.W., on Friday, June 26th, at 4 p.m., when the result of the voting for pensioners, annuitants, and foundation scholars will be announced.

The next meeting of the Medical Society of Individual Psychology will be held at 11, Chandos Street, Cavendish Square, W., on Thursday, June 11th, at 8.30 p.m., for a discussion on "The treatment of sexual impotence by the methods of individual psychology."

The annual general meeting of the Paddington Medical Society will be held on Tuesday, June 9th, at 9 p.m., at the Great Western Royal Hotel, Paddington. The president (Dr. G. de Swietochowski) will deliver an address entitled, "Medical ideals and practice." Non-members will be welcome. The honorary secretary is Dr. J. Cohen, 23, Westbourne Park Road, W.2.

The annual meeting of the Association of Local Government Medical Officers of England and Wales (formerly the Poor Law Medical Officers' Association) will be held on Thursday, June 11th, at 6 p.m., at the Holborn Restaurant, with the president, Sir Arthur Newsholme, in the chair. The meeting will be followed by an informal dinner (morning dress) at 6.30 p.m. Any local government medical officer will be welcome to the meeting and the dinner, the charge for which will be 8s. 6d. Notice of intention to be present should be sent immediately to the honorary treasurer, Mr. Frank Greenwood, Bank Chambers, 159–152, High Street, Stoke Newington, N.16.

At the annual meeting of the Fever Hospitals Medical Service Group of the Society of Medical Officers of Health, to be held at 1, Upper Montague Street, Russell Square, W.C., on Friday, June 12th, at 3.15 p.m., a paper on "State control of therapeutic substances" will be read by Dr. Percival Hartley of the Standards Division, National Institute for Medical Research. Visitors who are interested in this subject will be welcome.

On May 31st a Sunday post-graduate course was started at Charing Cross Hospital. Lectures will be given at 10.45 a.m. and at 11.45 a.m. every Sunday until July 26th. Further information can be obtained from the secretary of the hospital.

Particulars of the lectures and demonstrations arranged for next week by the Fellowship of Medicine will be found at page 232 of the *Supplement*. The special evening lectures to candidates for the M.R.C.P. are being continued; these are delivered at 11, Chandos Street, Cavendish Square, at 8.30 p.m.; tickets, 10s. 6d. each lecture, may be taken at the lecture hall. A demonstration on radium will be given by Mr. Duncan Fitzwilliams on June 8th at 2 p.m., at the Mount Vernon Hospital, Northwood, and on June 9th, at 5 p.m., Mr. Lowndes Yates will demonstrate cases at the Central London Throat, Nose, and Ear Hospital; there is no fee for attendance at either demonstration. The remaining special courses for June are: diseases of children, at the Children's Clinic and other hospitals; tropical diseases, at the Hospital for Tropical Diseases; medicine, surgery, and the specialties, at the Prince of Wales's Hospital; fractures, at the Royal Albert Dock Hospital; diseases of children, at the St. John's Hospital, Lewisham; proctology, at St. Mark's Hospital; and cardiology, at the National Heart Hospital. Syllabuses and tickets from the Fellowship of Medicine, 1, Wimpole Street, W.1.

The next award of the medal of the Hunterian Society of London will be made in 1932, and is open for competition to all general practitioners of Great Britain, Ireland, and the Channel Islands. The medal will be awarded for the best essay on some medical subject chosen by the writers, and essays must reach the honorary secretaries on or before December 31st, 1931. The president and council have decided that the medal shall be of gold, and not of silver as heretofore. The rules governing the award may be obtained on application to the secretaries, Dr. D. C. Norris, 14, City Road, Finsbury Square, E.C.1, and Mr. Andrew McAllister, 79, Wimpole Street, W.1.

The annual congress of the Rumanian Medical Association will be held at Constantza from June 13th to 15th.

Under the auspices of the Association for Post-Graduate Teaching of the Hospitals of Paris a series of lectures and demonstrations on tonsil surgery will be given from June 15th to 17th at the Necker Hospital for Children. The subjects to be dealt with include the evolution of tonsillar surgery; indications and contraindications from the laryngological standpoint; pre-operative steps; various techniques; post-operative care and the treatment of complications; and the medical point of view. The demonstrations will be conducted in English as well as in French. The fee is 300 francs, and inquiries should be addressed to Dr. Magdelaine, Hôpital Necker-Enfants Malades, 149, Rue de Sèvres, Paris.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are *MUSEUM* 9861, 9862, 9863, and 9864 (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:
EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.*
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*
MEDICAL SECRETARY, *Medisecra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS

Leucoplakia

"G.P." (London) writes: Can any of your readers suggest treatment for a persistent case of leucoplakia of the mouth and tongue? Balsam of Peru and all the usual remedies for stomatitis have already been tried. Apart from this, the patient is in good general health.

Gestation Period in Animals

"Z" writes: Could any of your readers refer me to a book which gives the periods of gestation for animals, and their average weight at birth?

*** Flemming's *Veterinary Obstetrics* (new edition) gives the data for the domestic animals. For non-domestic animals *Tabulae Biologicae* might be consulted. If further information is required our correspondent might write to the Director, Imperial Bureau of Animal Genetics, Edinburgh University, stating a definite query.

Scleroderma with Pernicious Anaemia

Dr. ALEX. PATTON (Widnes) writes: Can any reader enlighten me on the association of brawny, pigmented skin with Addison's disease or the anaemias, particularly as regards etiology? I have a patient whose blood picture is that of pernicious anaemia, with achlorhydria and signs of subacute spinal degeneration. He has also a low blood pressure, marked skin pigmentation, and hard, brawny skin, especially over the legs and fingers. Thirteen years ago he had acute phosgene poisoning, giving the usual chest symptoms. He has also suffered at intervals from dermatitis of the hands. One would be interested to hear of similar cases, evidently toxic, and whether they often arise spontaneously or industrially.

Inflammation at Site of Old Vaccination Scars

Dr. L. J. HARDY (Hull) writes in reply to Dr. W. J. Ledgerwood's enquiry in the *Journal* of May 23rd (p. 919): I would suggest that the lesion is self-inflicted. The age, sex, and site of lesions (left arm) and the fact that they (probably) did

not resemble any straightforward skin disease are in conformity with my suggestion as to their origin. Treatment should be suggestive—that is, paint with brilliant green, and warn the patient that if anything else is applied severe results will follow, even to necessity for amputation! The alternative is strict isolation and observation in hospital.

Income Tax

Professional Residence : Subletting

"LEASEHOLDER" sublets three consulting rooms unfurnished for, say, £1,000. The relative Schedule A assessment is £392. Should the £1,000 be returned for assessment under Schedule D or any other schedule?

*** The judicial decision referred to in a recent answer in this *Journal* was that of the House of Lords in the case of Salisbury House Estate Ltd. *v.* Fry. The facts in that case were, briefly, that the amount of office rents received by the company less the company's annual expenses were in excess of the amount of the Schedule A assessment. The revenue authorities sought to assess the excess under Schedule D, and the company contended that (apart from any profit made directly on the payments for cleaning services, etc.) rents of unfurnished sets of rooms were assessable under Schedule A *only*, and that Schedule D was not applicable. The House of Lords accepted the company's contention, and the Schedule D assessment was quashed. Applying that decision to the facts stated by "Leaseholder," it would appear that the £1,000 cannot be charged under Schedule D, and that to the extent to which it is not covered by the Schedule A assessment it escapes income tax.

Cash Basis

"A. T. V. D." asks, "Are doctors' taxes made up on the actual bookings (less known bad debts), or are they taxed on the actual money earned during the past year?"

*** It is beyond dispute that "the full amount of the balance of the profits or gains"—to quote the words of the statute—on which the tax is chargeable should strictly be calculated by deducting the year's expenses from the year's bookings less a carefully estimated allowance for bad and doubtful debts. The point has not been the subject of a judicial decision, because no one has considered it worth pursuing to the High Court. At the same time the computation of a proper allowance for doubtful debts is so difficult in the case of a medical practitioner that the income tax authorities have for many years accepted returns based on cash receipts less expenses. The reason is that, taking one year with another in a normal practice, the results are the same. Where circumstances are such that this assumption is upset, the authorities refuse, as they are entitled to do, to accept the cash basis—for instance, where a practice is new, or is expanding rapidly, so that the cash profits are lagging behind the true profits.

Sickness Insurance Premiums

"F. B. T." inquires whether these premiums can be treated as professional expenses if, as he understands, the payments for sickness benefit would not be taxable.

*** The position is as "F. B. T." suggests. The payments are not made in the performance of the work of the practice, but rather to provide for someone else being paid to carry it on if the insured is not able to do so. Consequently they cannot be deducted as professional expenses, and, as a natural corollary, the benefit payments resulting from the policy are not professional receipts, and are not liable to income tax.

LETTERS, NOTES, ETC.

Axis-traction Forceps

Dr. R. H. BOTHAM (Darlington) writes: I have been interested in the correspondence relating to Wagstaff's forceps in the *Journal*, and am in agreement with the writers who approve of them. But the chief point of interest in connexion with them is whether their method of achieving axis-traction, or that used in Tarnier's forceps and its modifications, is the correct one. I think this question should be submitted to some expert in mechanics. For myself, I think Wagstaff is right, and that the method used by Tarnier and his imitators is needlessly elaborate, and therefore needlessly expensive. My own forceps, a pair of Assalini forceps with the handles curved back, are made on the same principle, and achieve, I think, an even greater simplicity than Wagstaff's.

Dr. MICHAEL STARK (Wanstead Park, Essex) writes: In 1923 my father, the late Dr. Campbell Stark, published his *Index to General Practice*, in which he strongly advocated the use of Wagstaff's midwifery forceps, and always insisted that, on the ordinary bed, it was much easier to apply the upper blade first. To facilitate this he had his forceps made with the lock reversed. I understand that quite a number of these instruments have been ordered since 1923, but that some practitioners have not found them as easy of application as they were led to suppose. I have recently had a visit from a representative of one of the leading instrument makers, and was surprised to find that they had never supplied these forceps with the reversed lock. In view of the number of these forceps that have been ordered I thought I would seek this means of pointing out a possible explanation of the difficulty that users may have experienced.

Neoplasm following War Service

Dr. RICHARD KERRY (Montreal) writes: A case somewhat similar to that referred to by Mr. Howard Collier in your issue of April 18th (p. 666) came to my notice a couple of years ago. A man who had been gassed twice, on active service, was found to have a large fungating growth in the larynx early in 1927. I took the ground that the lesion had developed in tissue which had been damaged during the war, and that the man was a war casualty. After some argument the Pensions Board granted the man a pension, which, unfortunately, he did not live to enjoy.

Garden Sanitation

Reference has lately been made in these columns to a great teacher and experimenter in the principles of rural sanitation, Dr. George Vivian Poore of University College Hospital, London, who died in 1904. Some of our readers will be glad to know that work is going on near Cheltenham towards a memorial to him—a scheme which was started about a year or more ago. A small estate of ten workmen's houses is to be fitted out with the garden sanitation which Poore advocated; and, later, it is hoped, a small building will be erected in his memory. Professor J. W. Scott of University College, Cardiff, who is supervising the work for the National Homecroft Association, hopes by the end of this summer to be able to show at least two models complete, and perhaps more if funds allow. He will be glad to communicate with readers interested in Poore's work and memory, and any such would be welcomed at a meeting of the committee in charge, which is to be held at 2.30 p.m. on Thursday, June 11th, at Church House, Dean's Yard, Westminster. Dr. F. G. Crookshank will be in the chair, and Professor Scott will present a report.

Medical Golf

The annual summer meeting of the Medical Golfing Society was held on May 28th at Walton Heath. The ninety-six competitors were the guests of Lord Riddell, and greatly enjoyed his hospitality. Results were as follows: *Lancet* Cup (scratch), Dr. W. H. Lamplough, all square. Henry Morris Cup (handicap), Dr. W. H. Lamplough, 2 up. Class 1: First prize—Dr. J. Wallace. Second prize—Dr. W. Gilliatt. The best score for the last 9 holes was returned by Mr. George Dawson. Class 2: First prize—Dr. C. H. Ilott. Second prize—Dr. C. Branwell. The best score for the last 9 holes was returned by Dr. Rolf Creasy. Foursomes: Winners—Mr. Rowley Bristow and Dr. W. H. Lamplough, after a tie with Dr. Galletly and Dr. McGrath. The Knock-out Tournament and Milsom Rees Cup was won this year by Sir Kenneth Goadby, the runner-up being Dr. Bathurst.

A Warning

A London surgeon informs us that a young man, about 25, fair complexion, medium height, who states that his father, now deceased, was a doctor at Purley, and that he is an officer in the Flying Corps, is calling on consultants known to his late father and borrowing small sums of money. Our correspondent has put the matter in the hands of the police, and we advise others to do the same.

Vacancies

Notifications of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 74, 75, 76, 77, 78, 79, 82, 83, and 84 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 80 and 81.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 231.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

543 Benign Acute Pulmonary Tuberculosis

G. G. ORNSTEIN, D. ULMAR, and E. L. DITTLER (*Amer. Rev. Tuberculosis*, March, 1931, p. 223) from an experience of 58 cases describe an acute form of tuberculosis which is sudden in onset, of brief duration, and ends in complete resolution. The symptoms are very mild, following a period of perfect health. They consist of a slight cough with scanty expectoration lasting only a few days; haemoptysis, streaked or copious, was an initial symptom in 43 per cent. of the cases. Such haemoptysis associated with slight cough and expectoration, rapidly disappearing and leaving the patient apparently quite well, suggests the acute benign form of tuberculosis, while a history of recent contact with a case of tuberculosis renders the diagnosis practically certain. The *x*-ray findings are important, extensive dense homogeneous shadows developing rapidly and diminishing gradually, or by irregular absorption, producing an appearance suggestive of cavitation. Tubercle bacilli must be searched for early, since they are generally to be found only within the first few days of the onset. In 22 per cent. of the cases there was a definite history of exposure to tuberculosis, and it is essential for such patients to be protected from the possibility of future contact with tubercle bacilli. Complete rest in bed until all *x*-ray evidence of lesions has disappeared is the only treatment needed, and the entire cycle, from the commencement to the completion of resolution, may not be longer than from six to eight weeks.

544 Relapses in Scarlet Fever

A. LICHTENSTEIN (*Acta Paediatrica*, March 15th, 1931, p. 379) states that a relapse in scarlet fever may be defined as the reappearance during the course of the disease of the typical symptoms, especially the exanthem, in which it is possible to produce an extinction reaction by convalescent or antistreptococcus serum. At the Stockholm Epidemic Hospital, of which Lichtenstein is the director, the frequency of relapses in scarlet fever was formerly 0.5 to 0.6 per cent. Recently, however, there had been a striking increase in their frequency, especially since 1925, when the incidence of relapses was 3.9 per cent., rising in the subsequent four years to 7.2, 7.1, 7.5, and 10 per cent. respectively. The relapses were commonest between the ages of 5 and 10 years, and in the third and fourth weeks of the disease, but might occur from the first to the twelfth. In most cases the symptoms were mild, but 56 out of the 213 cases were sufficiently severe to require serum treatment, and 4 out of 377 cases (1.1 per cent.) were fatal. Relapses were less frequent in cases receiving scarlet fever antitoxin or convalescent serum than in cases not so treated. Lichtenstein regards the recent increase of relapses as connected with the mild character of scarlet fever at the present time.

545 Syphilitic Arthritis

I. H. LLOYD-WILLIAMS (*Urol. and Cut. Rev.*, April, 1931, p. 225) states that syphilis of the joints may occur in either the secondary or the tertiary stage of the acquired disease, and also in the congenital form. The earliest manifestation is arthralgia, which frequently accompanies the roseola, and varies in intensity in different cases, being usually worst at night. In the late secondary or early tertiary stage the large joints such as the knees are most frequently affected, usually on both sides. The joints become swollen and more or less fusiform, and there is a variable thickening of the synovial membrane and surrounding tissues. As in other forms of chronic synovitis, there is apt to be some muscular spasm and wasting. The tertiary stage is characterized by gummatous deposits, usually in the perisynovial tissues, but sometimes in the cancellous tissue of the ends of the bones, whence it may invade the cartilage. In congenital syphilis the usual form encountered is a chronic synovitis similar to that seen in secondary syphilis. Charcot's disease occurs in locomotor ataxy, and as the disease progresses causes complete disorganization of the joint.

546 Encephalitis in Undulant Fever

G. SUÁREZ (*La med. Ibera*, March 14th, 1931, p. 389), who records an illustrative case, states that in contrast with the frequency of bronchitis, arthralgia, myalgia, orchitis, anaemia, splenitis, and other complications, involvement of the cerebro-spinal centres in Malta fever is surprisingly rare, although cases of meningitis have been described by Scherb and one of myelitis by Fernando Sanz. The present patient was a previously healthy youth, aged 19, in whom on the ninth day of an attack of Malta fever, contracted from eating goat's milk and cheese, there suddenly developed violent delirium followed by complete flaccid paralysis and insensibility; coma and loss of sphincter control were followed by death. Slight nuchal rigidity during the last two days of life showed that the meninges were involved. The cerebro-spinal fluid was sterile, and showed a well-marked albumino-cytological dissociation, there being only 0.30 gram albumin with 610 cells to the cubic millimetre. No mention is made of a necropsy.

Surgery

547 Torsion and Volvulus of the Stomach

Total volvulus and complete torsion of the stomach are rare and have only recently been recognized as pathological entities. W. A. MORRISON (*Surg., Gynecol. and Obstet.*, April, 1931, p. 871) records a case of almost complete gastric torsion, remarkable because there was a complete interference, with stoppage of blood to the organ, which caused the patient's death. Becker states that a true volvulus is a rotation of the whole viscus between the pylorus and cardia, while torsion is a rotation about the other axis. The factors commonly associated by different authors with each condition are enumerated. Usually the circulation appears to be more or less resistant to the torsion, and is not greatly disturbed. The usual sequel is perforation of the stomach due to distension, unless treatment is instituted or death supervenes. Pathognomonic symptoms are absent. The onset is sudden, with rapid appearance of acute gastric pain, retching, absence of peristaltic movements, perhaps facial cyanosis, and a quick pulse unassociated with high temperature. According to Pilcher, an immediate diagnosis can be made when there is vomiting which suddenly stops and is followed by an immediate increased distension. Immediate operation is imperative. The treatment of volvulus comprises puncture of the stomach, evacuation of gas and fluid, reduction of the torsion, and gastroenterostomy. In torsion due to a stenosis or other conditions, the pathological lesion should be treated by acceptable methods. The formation of a fistula may be indicated as a complementary operation.

548 Electro-surgical Scalpel in Renal Surgery

W. W. SCOTT (*New York State Journ. Med.*, April 1st, 1931, p. 394) records notes of five cases operated upon for renal calculi. The edge that it was only necessary to reduced the haemorrhagicle in one of them; in this case clamp the vascular pisable to resect a dilated lower calyx, it was considered adme a favourable site for renewed stone lest it should becor emarks that the control of bleeding formation. Scott r

permits quicker and better operative work; with the necessity for fewer sutures there is less loss of renal function, since Moore and Corbett demonstrated in 1911 that the suturing necessary to control haemorrhage decreased the kidney function more than the actual sectioning. By eliminating the possibility of renal injury resulting from compressing or clamping the vascular pedicle a distinct advantage is gained, especially when operating for calculi in a sole remaining kidney of low functional value. Since bleeding is very moderate, necessitating but little suturing for its control, the chances of recovery are increased in proportion to the amount of functional parenchyma preserved. A mattress suture, as described by Deming, was used in one of these cases. A combination of the electro-surgical scalpel with the Deming suture is of great value in operations upon the renal parenchyma. A spark-gap generator developing a current which readily cuts and simultaneously seals severed vessels with the least possible destruction of parenchyma is essential. Since the generators have not yet been properly standardized, each machine must be tested on animals.

549 The Latero-posterior Incision for Appendicectomy

A. L. SORESI (*Amer. Journ. of Surg.*, March, 1931, p. 552) describes a latero-posterior incision for appendicectomy which permits direct access to the base and whole of the appendix, and obviates the disadvantages of the abdominal route. This incision, parallel to the axillary line, begins, according to the thickness of panniculus adiposus, more or less close to the twelfth rib, and extends to the pelvis; it runs about 2 cm. behind the anterior superior iliac spine. This exposes in succession the fascia of the external oblique, that muscle, the internal oblique, and the transversalis. The fibres of these muscles are separated, not incised; the peritoneum is incised parallel to the skin incision, thus exposing the caecum, which is grasped and gently pulled upward to reveal the base of the appendix. This incision is ideal only for appendicectomies and not for exploratory laparotomies. It renders appendicectomy safer when severe complications are present, such as retrocaecal appendix and abscess. It decreases shock, obviates packing and much retraction, allows perfect drainage, and does not cause any post-operative complications, such as adhesions or ventral hernia. The procedure is speedier than any other, and can easily be performed under any form of anaesthesia. Moreover, the patients are more comfortable after such an appendicectomy. Pus in a localized abscess can be evacuated without infecting the general peritoneal cavity. A technique is described and advocated for subserous appendicectomy which renders the operation safer, easier, and quicker even if dense adhesions are present.

Therapeutics

550 Treponeme Therapy in Syphilis

G. VERROTTI (*Rinascenza Med.*, February 1st, 1931, p. 57) reports seven cases of syphilitic superinfection as a possible form of treatment. In one case of malignant syphilis the spontaneous lesions disappeared during the development of the induced lesions, while in another less severe the former disappeared before the development of latter. In both instances specific treatment was after the experimental inoculations, and this cured the superinfected lesions. There were no re- years. In another case with neurological

Dr. R. H. BOTHAM (D. clinical and serological improvement ested in the correspondnstance the infected material for in the *Journal*, and amd by the author from a primary who approve of them. Bu and without the interposition in connexion with them is sted by Hilgermann; it was achieving axis-traction, or that and its modifications, is the cations near the primary question should be submitted to sonway. Although in such For myself, I think Wagstaff is right, lays the greater part, used by Tarnier and his imitators is obtained in every case and therefore needlessly expensive. My indirectly, humoral of Assalini forceps with the handles curv o. The dangers of superinfection suggested by Gougerot seem to be non-existent. The author concludes that his results and those obtained by others seem to justify the possibility of reinforcing in this way the chemotherapeutic treatment of syphilis, thereby obtaining unexpectedly beneficial results in neurological cases also.

551 Administration of Emetine in Amoebic Colitis

A. C. REED (*Amer. Journ. Med. Sci.*, April, 1931, p. 553) considers emetine a powerful, dangerous, and valuable remedy, the complete action of which is at present imperfectly understood. It must therefore be administered with great caution, a careful watch being kept for symptoms of poisoning, which appear in the gastro-intestinal tract, the nervous system, and in the circulatory apparatus. Thus excessive doses in animals cause gastric irritation, with vomiting, melaena, and collapse; in human patients acute diarrhoea may result from rapid overdosage or the cumulative effects of too long continued injections. In the nervous system there may be toxic manifestations, such as peripheral neuritis and oedema of the feet and ankles. Increase of the pulse rate and lowering of the blood pressure are danger signals, as also are dyspnoea on exertion and complaints of weakness. The treatment must therefore be adapted to the individual, but the total amount of emetine given in any one course must not exceed 0.010 gram per kilo of body weight. The injections should extend over ten to twelve weeks, and be started by a series of six daily hypodermic doses of emetine hydrochloride, each of 1 grain (0.065 gram) for adults of medium weight and aged up to 65. These are followed consecutively by six doses each of half a grain, making a total of 9 grains of emetine. Clinical experience points definitely to a maximum safe dosage of 12 grains in a single course. Subsequently arsenic is given by Reed in the form of stovarsol, and then chiniofon (yatren) by mouth and by rectal injections. A week is next devoted to tonic treatment with iron, strychnine, and quinine, and then 1 grain pills of bismuth emetine iodide are given three times a day. When necessary, emetine injections can now be resumed.

552 Oily Solutions of Insulin in Diabetes

H. CHABANIER, C. LOBO-ONEL, and E. LÉLU (*Presse Méd.*, February 14th, 1931, p. 219) report eight cases of severe diabetes where the ordinary aqueous solutions of insulin failed to give satisfactory results or had risen to the limit of safety. By substituting an oily solution excellent results were obtained. Since oily solutions take much longer to be absorbed, they enter the circulation more slowly than the aqueous solutions, and their effect is more continuous, so that a full daily dose in the morning suffices instead of the two or three necessary with aqueous insulin preparations. In some cases it was found possible to reduce the dose to one every other day. The authors do not suggest that oily solutions should replace watery ones in the ordinary case, for with oily solutions much care is necessary in regulating the times of taking food and testing the blood sugar; they reserve them for those cases in which, for one reason or another, it is inadvisable to push aqueous solutions, although the urinary and blood signs are not completely cured.

553 Trypaflavine in Typhoid Fever

M. L. GAWLER (*Thèse de Paris*, 1931, No. 63), who records ten illustrative cases in patients aged from 15 to 28, states that trypaflavine is an eminently bactericidal substance and one of the most powerful antiseptics known. Good results are obtained from its intravenous use in typhoid fever, in which it should be employed in the severest cases which show no tendency to react to other treatment. The administration of trypaflavine should be preceded and followed by estimation of the blood urea content, since the drug is apt to damage the renal cells. The dose injected intravenously should not exceed 0.005 gram for each kilo of body weight. The best dose is 0.2 gram injected every two or three days in a 1 per cent. solution. The most obvious result of the intravenous injection of trypaflavine is the fall of temperature; this is accompanied by improvement in the general symptoms.

Radiology

Ureteral Pyelography

554 A. BOECKEL and A. FRANCK (*Lyon Chir.*, January–February, 1931, p. 5) give their experiences and opinion on the value of examination by pyelography in 575 cases of various lesions of the kidney. Pyelography enables the surgeon, before operation is undertaken, to ascertain the topography and exact anatomical condition of the kidneys. It must not be employed in cases of uraemia, when fever is present, or during a renal haematuria. Before a successful pyelography can be secured the intestines must be evacuated, preferably by an oil purgative, and pulverized animal carbon be given to absorb gas; pituitrin is injected the night before. The opaque solution chosen varies according to the condition suspected, 5 per cent. collargol being used for pyelography of renal lithiasis, 10 per cent. collargol when a large hydronephrosis is diagnosed, and 30 per cent. sodium bromide in the majority of other cases. When sodium bromide is used, not more than 20 c.cm. must be injected into each pelvis; warmed solution is more easily tolerated. A successful pyelogram can also be obtained by means of an injection of air into the ureteral catheter, this method being known as pneumopyelography. The shadows by this means are less clear than with ordinary pyelography, but it has the advantage of being quite painless, and gives more reliable information, particularly in cases of renal lithiasis. Immediately before the pyelogram is to be taken an antispasmodic should be given, and under no circumstances should a general anaesthetic be administered, owing to the danger of over-distension of the pelvis. It is advisable to perform bilateral pyelography, since in cases of small hydronephrosis, of ptosis, and of tumours and their anomalies it is important that a comparison between the two kidneys should be available. Upon the result of the pyelography treatment must be decided, and this form of diagnosis is of special value in cases of renal calculus, nephroptosis, and malformations of the kidneys and ureters.

X-Ray Treatment of Primary Malignant Lymphadenoma

555 P. SCHLANGER and E. W. DE SCHLANGER (*Rev. Sud-Amer. de Méd. et de Chir.*, February, 1931, p. 141) state that in the acute lymphadenomatous type of Hodgkin's disease, seen in young previously healthy subjects, and characterized by the rapid development of large localized tumours and by early cachexia and fever, radiotherapy reduces the size of the tumours but fails to arrest the disease; sero-fibrinous pleurisy appears, indicating the approaching termination. Pleurisy due to mediastinal glandular involvement is not of such grave import, and yields to radiotherapy. In acute lymphadenoma and acute leukaemia, radiotherapy is useless except during an apyrexial period; if fever returns, this treatment should be abandoned. In untreated chronic lymphogranuloma, especially frequent in young subjects, although it may occur at any age, the localized tumours remain apparently stationary, but ultimately all the lymph nodes are involved, with gradual onset of fever and cachexia. Death occurs in from two to seven years. Radiotherapy improves, and sometimes cures, these cases; two patients remained cured after two years. Lymphosarcoma, whether of the spindle-celled or round-celled type, is very sensitive to *x* rays. Complete cure is rare, as the prolonged treatment necessary may cause skin lesions. Treatment should be given at intervals corresponding to the progress of the disease, and even very severe cases may sometimes yield to radiotherapy.

Radiography in Antral (Highmore) Diseases

556 R. G. BROWN (*Journ. College of Surg. of Australasia*, November, 1930, p. 151) believes that *x*-ray examination of the accessory nasal sinuses affords the only means of definitely ascertaining their pathological condition, and that it is an essential procedure in diseases of these cavities, especially when the symptoms are obscure. He deals only with antral conditions, and formulates certain rules for the taking of the plates. Films must be exposed to rays from proper angles and of the correct density; the head, film, and tube must be so fixed that the dense, unrequired structures will fall outside the desired field. Several exposures and positions are necessary; four views and stereoscopic pictures in at least one position should be taken. The patient must be in an upright position, and a Potter-Bucky diaphragm be used. The strength of current employed depends on the individual radiologist. The following four head positions are utilized by Brown: a modified occipito-frontal or postero-anterior, lateral or bitemporal, axial, and an oblique lateral. A series of typical cases illustrating the various conditions encountered in the antra is described. These are divided into two groups: those with alterations in the bony walls, and those with alterations in the antral contents. The former comprise malignant involvement, trauma by penetrating foreign bodies, alteration of the walls and invasion of the cavities by dental and dentigerous cysts, osteitis, osteomas, and conditions following antral operations. The second group includes acute and chronic inflammatory changes, cysts, hydrops, calculi, cholesteatoma, and tumours. In conjunction with D. A. WELSH, Brown also records a microscopical study of several muco-periosteal membranes removed from the antrum.

Obstetrics and Gynaecology

The Ureters and Menstruation

557 By radiography of the ureter after intravenous injection of a substance casting a shadow during its excretion by the urinary tract, O. SAITZ (*Zentralbl. f. Gynäk.*, February 7th, 1931, p. 347) found that two out of every three women showed a dilatation of the ureter during menstruation which was similar to that found in pregnancy. Dysmenorrhoea was reported by all patients showing such dilatation. It was also found in them that drainage of the ureter by a catheter relieved the pains of dysmenorrhoea; these pains returned and disappeared when the ureteral catheter was alternately blocked temporarily and then freed. Saitz is satisfied that in certain patients the sole cause of dysmenorrhoea is ureteral colic, and for such cases uses the term "ureteric dysmenorrhoea."

Etiology of Uterine Haemorrhage

558 C. F. FLUHMANN and DOROTHY L. MORSE (*Amer. Journ. Obstet. and Gynecol.*, April, 1931, p. 455) discuss the relation of uterine haemorrhage to the menstrual cycle and the pathological findings in such cases. Of 1,137 cases of haemorrhage from the uterus, 507 occurred in non-pregnant women, and 630 were associated with pregnancy. In non-pregnant women eight distinct categories were recognized according to the clinical signs. In menorrhagia, with no disturbance of the sequence of events in the menstrual cycle as regards the ovaries and endometrium, the most frequent factor was interference with the contractile power of the uterus, or hyperaemia of the pelvic organs. In the second class there was irregularity in the menstrual time factor, due to ovarian dysfunction, either of a primary endocrine nature or secondary to anatomical lesions. Endometrial proliferation was a third primary cause, possibly associated with infection or hyperplasia of the uterine wall, or with the appearance of submucous fibromyomas and endometrial polyps. Haemorrhage may also occur in the middle of the menstrual cycle at a time corresponding with the rupture of the Graafian follicle, the so-called ovulation bleeding. A type of haemorrhage characterizing hyperplasia of the endometrium is found when the menstrual periods become progressively more profuse or irregular, and end in continuous bleeding. During a period of amenorrhoea in non-pregnant women of child-bearing age haemorrhage may also result from a traumatic or ulcerative lesion of the uterus, following the previous removal or destruction of the ovaries. New growths or inflammation may give rise to bleeding in consequence of trauma

or ulceration of the cervix or endometrium. After the climacteric, irregular haemorrhage may be due to these causes, and in rare cases ovarian new growths may affect the endometrium and thus give rise to loss of blood.

559 Accelerated Growth of Ovarian Tumour after Radiotherapy

G. VOYADZOPOULOS (*Bull. Soc. d'Obstét. et de Gynécol. de Paris*, February, 1931, p. 115) quotes a case in demonstration of the fact that insufficient penetration with *x* rays will accelerate the growth of a tumour rather than cause it to shrink. The effect upon the tumour appears to be entirely due to the intensity of the irradiation. Above a certain strength the irradiation is favourable; below, it acts in the opposite way, and appears to excite the epithelial tissue instead of destroying it. The author's patient was a woman, aged 50, who had an inoperable cancerous mass of the right ovary. Ten days after the exploratory operation, her general condition being satisfactory, she was submitted to *x*-ray treatment, being irradiated on twelve occasions for a quarter of an hour at each time, and then discharged. One month afterwards the tumour was found to be considerably larger; in addition, a small tumour had appeared in the left ovary. The patient died one month later. The author considers that the *x*-ray administration certainly accelerated death. Additional confirmation of this view is given in a note by the radiographer, Lehman, who states that while waiting for a new transformer for his apparatus a provisional transformer was installed. The usual apparatus gave a tension of 250 kilovolts, the rays being filtered through 0.8 mm. copper and 1 mm. aluminium. The temporary apparatus gave 150 kilovolts, and the rays were filtered through 0.5 mm. copper and 1 mm. aluminium. The four patients who were treated by the temporary apparatus all presented an aggravation of their lesions at the end of a week, after having received a dose of 4,000 R during this period. The aggravation was most marked in the case in which treatment was least advanced. Lehman considers that treatment applied with a voltage of less than 200,000 excites the growth of a neoplasm.

Pathology

560 Etiology of Disseminated Sclerosis

P. LÉPINE and P. MOLLARET (*Bull. de l'Acad. de Méd.*, March 24th, 1931, p. 512) discuss the morphological and cultural characters of *Spherula insularis*, the micro-organism described by Chevassut as the probable causative agent of disseminated sclerosis. In order to substantiate or refute the findings of this investigator, the present authors conducted a series of experiments on twelve undoubted cases of the disease and six control cases, and also comparative tests of each cerebro-spinal fluid, with either physiological saline solution or artificial cerebro-spinal fluids. Though Chevassut's technique was faithfully followed, Lépine and Mollaret were unable to confirm her findings either by microscopical examination or by a study of the ionic concentration of the culture media. They attribute the microscopical appearances reported (spheres and granules) to flocculation of certain elements of the human serum used in the cultures. No changes were noted in the *p*H of the media which would favour growth of a living virus; such changes as were noted were contrary to this hypothesis.

561 The Intrinsic Carbohydrate Metabolism of the Skin

D. M. PILLSBURY (*Journ. Amer. Med. Assoc.*, February 7th, 1931, p. 426), acting on the evidence that there is an association of a high carbohydrate intake with various disorders of the skin, has undertaken experimental studies on the intrinsic carbohydrate metabolism of the skin. From recent work it would appear that: (1) the skin may serve as a temporary storehouse for large amounts of dextrose; (2) that there is in man a fairly constant ratio between the dextrose content of the skin and of the blood, but that, following ingestion of large amounts of dextrose, this ratio may be disturbed; (3) that the skin contains diastatic and glycolytic enzymes; and (4) that, in common with all other tissues that have been studied, skin cultures *in vitro* give off lactic acid. It has been satisfactorily demonstrated that glycogen is synthesized from blood dextrose in the liver, and probably in the muscles; that lactic acid is formed from muscle glycogen during exercise; and that much of the lactic acid so formed is re-synthesized into glycogen by the muscle and liver. Pillsbury's experiments were directed towards determinations of the lactic acid content of the normal skin of starved and well-fed animals, and study of the formation of lactic acid during the incubation of skin samples. He found that this acid was normally present in the skin, and that its formation *in vitro* was a consistently demonstrable finding in normal skin, except when the skin had been previously frozen. In the presence of dextrose in the incubating medium, especially in phosphate buffer solution, lactic acid formation was increased. The lactic acid level of skin tends, he found, to be low in starved animals and higher in well-fed animals. Decreased oxygen tension has no significant effect on lactic acid formation by the skin *in vitro*. Pillsbury hopes that the value of these experiments lies in the adaptability of the method to the study of the metabolism of the skin in pathological conditions.

562 The Search for B. coli in Water

F. DIENERT and P. ÉTRILLARD (*Ann. de l'Inst. Pasteur*, March, 1931, p. 277) discuss the value of the different methods employed for demonstrating the presence of *B. coli* in a water supply. The usual method in France consists in adding the water to a liquid medium containing 0.1 per cent. phenol. The rationale of this method lies in the assumption that the phenol will inhibit the growth of *B. coli* less than that of other organisms present. The authors consider this assumption doubtful; when other organisms are present in large numbers, and *B. coli* is relatively scarce, then it may be completely overgrown, and its presence not detected. To avoid this disturbing element introduced by the presence in varying numbers of other organisms, they recommend the use of solid media. The organisms in the water are concentrated by the addition of alum, which causes 95 per cent. of them to undergo sedimentation, and the precipitate is then plated out directly, by the pour method, on to a suitable selective medium such as endo or litmus lactose agar. Each organism has then the opportunity to develop, uninfluenced by the activities of other organisms. Besides looking for *B. coli*, the authors strongly recommend the search for organisms of the typhoid-paratyphoid group. For this purpose they use a lead acetate medium, on which *B. coli* produces colourless colonies, and the typhoid-paratyphoid organisms black colonies. These two tests are of considerable value in judging the potability of a given water supply. In practice *B. coli* is often found in contaminated waters in the absence of organisms of the typhoid group, whereas the reverse finding is uncommon. A water that contains neither *B. coli* nor organisms giving black colonies on lead acetate medium they regard as perfectly satisfactory for drinking.

563 Renal Function Tests in Hypertrophy of the Prostate

J. JAKSY (*Bratislavské Lekárske Listy*, March, 1931, p. 122) tested the function of the kidneys in fifty patients with hypertrophy of the prostate, the procedures he employed being: (1) the determination of the blood urea; (2) the estimation of Ambard's constant; and (3) the injection of phenol-sulpho-phthalein. The values obtained were compared with each other and the clinical condition. The author concludes that the most reliable information is obtainable from the phenol-sulpho-phthalein test. Disturbances of the hepatic circulation may retard the elimination of the dye, but any operation is known to be contraindicated in such cases. Prostatectomy was undertaken whenever more than 40 per cent. of the injected phenol-sulpho-phthalein was eliminated within the first seventy minutes, and in no single case did any post-operative renal complications appear.

Measuring Progress by the Therapeutic Yardstick

ANCIENT medicine set great store by "specifics." Paracelsus had his "Specificum Purgans." Cophon relied on mirobolanum or rhubarb in relieving constipation. Suppositories of honey and oxgall had their day in the fifteenth century.

Medicine has since made notable advances toward rationalism. In this day of therapeutic progress Agarol Brand Compound holds the foremost place. An exceptionally fine emulsion of mineral oil and agar-agar with phenolphthalein, it is not merely a laxative, but a remedial measure in the efficient treatment of constipation.

By introducing unabsorbable moisture, Agarol Brand Compound keeps the intestinal contents soft and makes their passage easy and painless. By *gentle stimulation* of peristalsis, it makes the result certain and aids in re-establishing normal bowel function.

One tablespoonful at bedtime —is the adult dose

Final decision on the true worth of Agarol Brand Compound rests with the physician. We will gladly send a liberal quantity with literature, for trial.

AGAROL BRAND COMPOUND *for Constipation*

RHEUMATOID and OSTEO-ARTHRITIS

Amidst the recognised difficulties in treatment of advanced cases of Rheumatoid and Osteo-Arthritis it is not generally realized that many patients have been restored to active life after being bedridden, suffering great pain for years, by Hoefftcke's Ambulatory Extension Treatment.

Many cases have been described by eminent medical men, some results of which are shown below.

FIG. 1.—December, 1921.

Case of Mrs. H., aet. 35.

FIG. 1.—Shows the knee-joint fixed in a position of partial flexion; patella ankylosed.

FIG. 2. — Shows after an interval of 9 years the improvement which resulted from 3 years' extension treatment—the complete restoration of the tibio-femoral joint which permits of free and painless flexion and extension.

This case was one of exceptional severity. In the average case the Extension Walking Appliance can be discarded in one or two years from the time of its first application.

FIG. 2.—April, 1930.

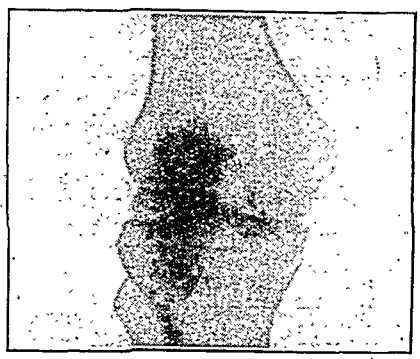

FIG. 3.—December, 1921.

FIG. 3.—Shows the irregularity of the outline of the articular surfaces as seen from before backwards. The interval between the bones is practically obliterated.

FIG. 4.—Shows the joint in an antero-posterior plane. Note the restoration of the outlines of the articular surfaces and the formation of a practically normal interval between the bones.

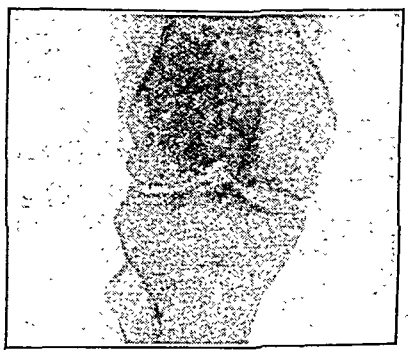

FIG. 4.—April, 1930.

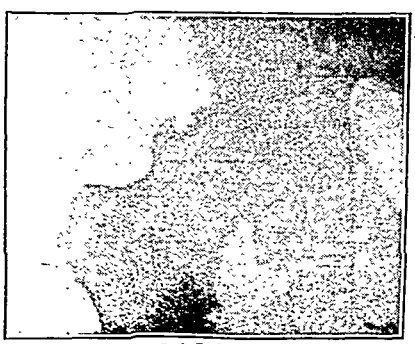

FIG. 5.—July, 1929.

Case of Mr. S., aet. 68.

FIG. 5.—Shows the hip-joint practically ankylosed in the adducted position. Patient hardly able to walk with great pain.

FIG. 6. — Shows spike absorbed; cavity filled in; head of femur covered with new cartilage, resulting in free abduction with full painless movement in the joint.

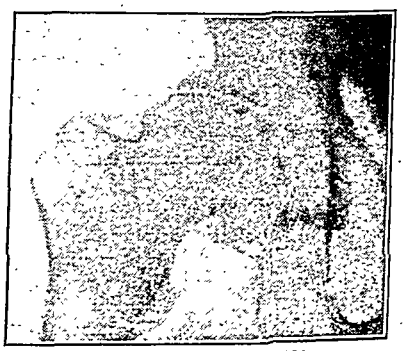

FIG. 6.—February, 1931.

Particulars and illustrations of this treatment will be forwarded on application, and original radiograms of these and other cases can be shown

by

CAREL A. HOEFFTCKE, 7, Harley Street, London, W.1.

SURGICAL SERVICE
SALTAIR

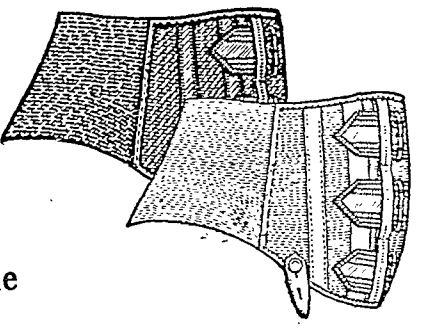
SALTAIR SURGICAL SERVICE

Guarantee

"We guarantee to alter, exchange, or accept the return of any appliance without cost, ordered by the Medical Profession, if not found suitable within fourteen days from date of supply."

Salt and Son Ltd.

Seasonal Changes



The unavoidable restrictions imposed by the ordinary surgical appliances often tempt patients to discard them during the summer months.

SALT'S
Specially Light Summer-time APPLIANCES

overcome all possible objections to the wearing of appliances during warmer weather.

Salt's summer-time appliances are light, comfortable, and afford complete freedom of movement, with the proper and necessary support required.

Patients who value hygiene will appreciate the welcome change from the ordinary appliance, enabling the latter to be released for cleaning and repair.

London Consulting Rooms:
"OAKLEY HOUSE," 14-18, Bloomsbury Street, W.C.1.
Female Fitters in attendance Monday to Friday.
Orthopaedic Mechanician Wednesdays only.
By Appointment.

DEAF DOCTORS

AND DEAF PATIENTS

HAVE proved "ARDENTE" a boon—a Heart Specialist whose work is so dependent on his hearing writes: "'Ardente' is a godsend to me"; without "ARDENTE" he is, to all intents and purposes, "stone" deaf; with "ARDENTE" he carries on his work—what better testimony to "ARDENTE" merit?

Mr. Dent makes a Stethoscope specially for deaf Doctors—the only one of its kind, which is widely used and praised. Doctors whose work lies amongst the deaf prefer to prescribe "ARDENTE" because they know that "ARDENTE" is the only individual method in the whole deaf world (no mass production way can ever succeed with human disabilities) and they know what "ARDENTE" service stands for to the deaf. Many who are deaf use "ARDENTE."

"ARDENTE" is entirely different and uncopyable and succeeds in widely-differing cases. A full range covers the needs of those suffering from varying forms and degrees of deafness and tinnitus. Minutely adjusted to the requirements of the case for young, middle-aged, or old, and so sensitive as to have the desired effect even in middle-ear and nerve cases, bringing into action and stimulating the auditory system, enabling it to function naturally and saving atrophy. "ARDENTE" can be used or not at will, and is sold under guarantee.

"ARDENTE" is the choice of Doctor and patient—only after test and hearing, or from prescription or particulars, is "ARDENTE" fitted, toned, adjusted, and supplied.

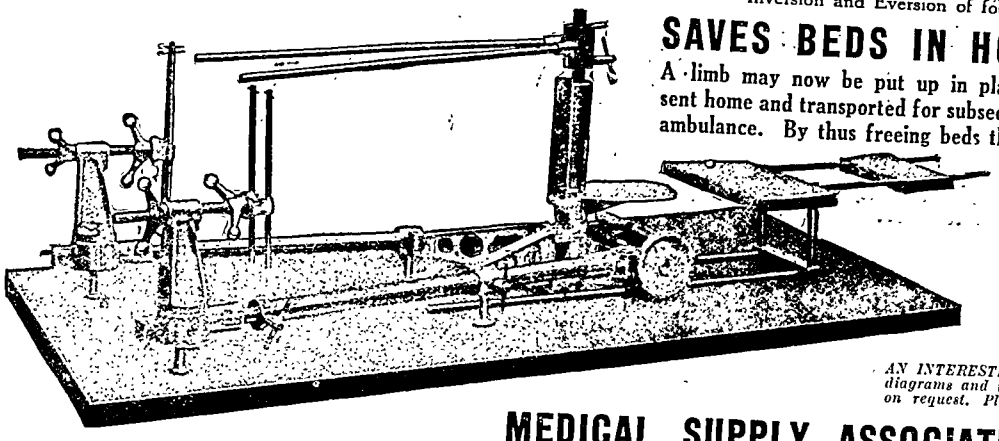
An IMPROVED and MODIFIED

Portable Traction Apparatus

An exceedingly efficient and convenient apparatus for putting up in plaster the lower limbs or trunk; also when applying bone plates or Parham and Martin's Bands to long bones of the lower extremity. Provides the more essential movements of expensive and bulky Orthopaedic tables at a fraction of the cost.

Quickly adaptable for the following positions:

Extension of whole lower limbs.
Movements about hip-joint:
Abduction to any degree—
Hyperextension—Flexion—
Internal and External Rotation.
Flexion of knee-joint.
Inversion and Eversion of foot.



SAVES BEDS IN HOSPITALS

A limb may now be put up in plaster, the patient sent home and transported for subsequent treatment by ambulance. By thus freeing beds this new apparatus saves its cost many times over.

Folds compactly for storage or transit in plywood case 35 in. × 15 in. × 11 in.

AN INTERESTING LEAFLET giving diagrams and instructions, post free on request. Please ask for a copy.

Your enquiries respectfully solicited.

"VARIBAN"

Elastic Plaster BANDAGE

MADE from a specially woven selvedge material, possessing very elastic properties, evenly spread with an Antiseptic Zinc Oxide Paste. Self-adhesive, readily conforming to the shape of the limb, and when carefully applied forms an even surface dressing which will not crease or slip. Firm support. Easy to remove. Extensively used in many well-known hospitals for the treatment of VARICOSE ULCERS, VARICOSE VEINS, SURGICAL and ORTHOPAEDIC CASES, etc. Their application for treatment of Varicose Ulcers, etc., does not necessitate the patient lying-up; in fact, permits the continuance of light duties. Ensures rapid healing.

SUPPLIED in WIDTHS

2"	2½"	3"	
1/7	1/9	2/-	EACH

When stretched measure six yards (approximately).

SAMPLE 3 in. "VARIBAN" ELASTIC PLASTER BANDAGE sent POST FREE on receipt of P.O. for 2/3.

"CELLANBAND"

PASTE BANDAGES

in the Treatment of VARICOSE ULCERATION, PHLEBITIS, etc.

MESSRS. CUXSON, GERRARD & CO. Ltd. have pleasure in informing the members of the medical profession that they are now manufacturing Paste Bandages—under the descriptive name of "Cellanband"—strictly according to the formula mentioned in the article quoted below.

"The paste-bandage constitutes a definite improvement upon the methods so far available, both in convenience of application and in the results obtained."
(Vide article on page 560, "B.M.J.," Oct. 4th, 1930.)

MUCOUS AND OTHER FORMS OF COLITIS

CONDITIONS of Colitis occur at all ages, and lead to much suffering, ill-health and chronic invalidism. They are caused by a great variety of bacteria, which, owing to a loss of resistance on the part of the mucous membrane of the colon, maintain a chronic infection, with inflammation of this portion of the intestinal tract.

Vaccine therapy is frequently tried in this condition with disappointing results, as it is pure chance if the causative organism is isolated from the host of bacteria present.

The rational treatment is obviously to administer an efficient germicide which will attack and destroy *all* the bacteria present. Kerol is the one substance which possesses this power, and its administration has cured many a case of mucous colitis.

For intestinal disinfection, use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

STANIFORM

Regd. BRAND. Trade Mark.

METHYL STANNIC IODIDE

OINTMENT
Immediately stops the pain in all cases of burns, scalds, etc.

DUSTING POWDER
For application where a greasy substance is counter-indicated.

LINIMENT
Remarkably effective in treatment of Rheumatoid Arthritis.

LOTION
A anacea for Mosquito and other insect bites. Most effective for all purposes where Tr. Iodine is employed. Does not stain the skin and there is no sting.

TABLETS
Staniform being an organic compound is more easily assimilated than the Tin preparations at present in use.

Supplies may be obtained through the Wholesale Druggists, Druggists' Sundriesmen, or Dental Supply Companies.

What the Profession says

The following are some recent unsolicited testimonials reported to the Manufacturers by Medical Men:

"I have treated with 'Staniform' a very bad scald of chest in a child, who had boiling water spilt over her. It healed completely in fourteen days without a scar."

"I have tried 'Staniform' in the Out-patients' Department and both Nursing Staff and myself were amazed at results obtained. Long-standing, non-healing skin wounds healed after few applications."

"This is to certify that 'Staniform' has been used with great success in the Emma-Kliniek (Utrecht, Holland), in cases of bed-sores, in burns of heat and X-rays."

Similar testimony has been received from a large number of medical men when "Staniform" has been used for the treatment of Burns, Wounds, and Skin Ailments

STANIFORM is used in Leading Hospitals.

STANIFORM over a wide field of clinical experience has exhibited positive curative properties. Combining the well-known usefulness of Tin in staphylococcic infections with the powerful germicidal properties of Iodine, Staniform is indicated generally in local inflammations, inducing an immediate soothing effect with rapid healing.

THE DOCTOR'S CHINA TEA

WHY IT IS PRESCRIBED FOR GASTRIC PATIENTS.

When ordinary tea is out of the question it is essential that only really good China should be drunk. The Doctor's China Tea has won the enthusiastic approval of practitioners simply because it is a perfect blend of a good China leaf with all excess tannin eliminated. It can therefore be prescribed for invalids and dyspeptics with safety—it has no ill after-effects.

ESTABLISHES REGULAR EVACUATION

It is admitted that the large majority of patients suffer from the direct or indirect effects of constipation. It is often difficult to educate them to combat these evils. Some are ignorant, others apathetic, while many of them dread the griping pains and weakness occasioned by the ordinary laxatives. Sal Hepatica is pleasant to take and both prompt and painless in action. It maintains the biliary secretion in a healthy fluid state, and ensures freedom from congestion and from that subacute inflammation of the gall bladder which is at present so common, especially amongst sedentary workers. Sal Hepatica does not create a condition of tolerance. It is, therefore, the laxative of choice in chronic constipation.

Samples for clinical trial will be forwarded on request to duly qualified members of the medical profession on application to Bristol-Myers Company, 112, Cheapside, London, E.C.2.

Sal Hepatica contains sodium sulphate, sodium phosphate, sodium chloride and lithia citrate in an effervescent medium.

Sal Hepatica

the proved medicinal, saline laxative and cholagogue.

SUCCESSFULLY PRESCRIBED FOR MANY YEARS

SULPHAQUA

IN THE TREATMENT OF

Skin Diseases, Rheumatism, Gout, Neurasthenic : : Conditions in Arthritic Subjects, Etc. : :

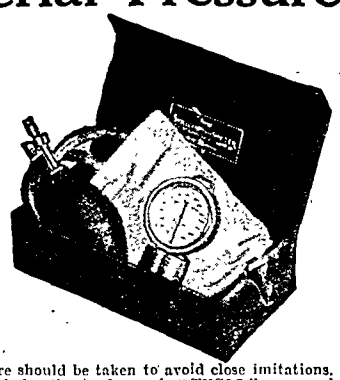
Accurate Arterial Pressure Readings



For visiting purposes the TYCOS Portable Sphygmomanometer amply fulfils the Physician's needs. Although one of the most delicate and accurate instruments of the medical man's equipment, the portable type as illustrated can be carried without fear of breakage. There is no glass tubing to break, no mercury to spill, and the readings can be verified at a glance by comparing the relation of the hand to the immovable zero.

Care should be taken to avoid close imitations. Look for the trade mark "TYCOS" engraved on the dial of every genuine instrument.

Obtainable from all reputable Instrument Dealers.

THE POSTAL ACCOUNT

It is often supposed that to live a long way from the nearest branch of a bank, or to be constantly unable to go to the bank in person, is a handicap to the enjoyment of the full advantages which, it is admitted, a banking account offers. Perhaps it is assumed that to conduct an account by post involves more letter writing, or is costly, or is not welcomed by the Bank. It is the aim of the Westminster Bank to dispel such misconceptions by a leaflet entitled *The Postal Account*, which explains the convenience of the method, and offers some clear suggestions.

The Secretary of the Bank will be pleased to send a copy on application

"... to the busy practitioner who needs to conserve the last ounce of energy, the absence of all effort in gear changing must count a great deal in a busy day's work..." A.J., M.D.

"Your Self-Changing Gear has been a perfect revelation. I now come in from a busy round with no sort of feeling of fatigue as the result of stopping, starting, and changing gear so many times as I needs must do. The relief from this work as compared with the old form of gear change is really rather remarkable."
M.B., Ch.B.

Arrange a Trial Run—Have an Armstrong Siddeley for a round of visits and notice what a difference the self-changing gear makes. It is something you have been waiting for for years.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or who wish to prevent recurrent attacks of mental trouble; temporary patients; and certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

HAYDOCK LODGE,
NEWTON-LE-WILLOWS, LANCASHIRE.

'Phone: 11 Ashton-in Makerfield.

For the reception and treatment of PRIVATE PATIENTS of both sexes of the UPPER AND MIDDLE CLASSES either voluntarily or under Certificate. Patients are classified in separate buildings according to their mental condition.

Situated in park and grounds of 400 acres. Self-supported by its own farm and gardens, in which patients are encouraged to occupy themselves. Every facility for indoor and outdoor recreation. For terms, prospectus, etc., apply MEDICAL SUPERINTENDENT.

COURT HALL, KENTON, EXETER,
SOUTH DEVON.

For the care and treatment of Ladies suffering from Mental Diseases. Limited to eight patients. Telephone: Starcross 19.

CLIFFDEN, TEIGNMOUTH, in connection with Court Hall, for early and convalescent cases. Cliffden is a large well-appointed house, with lovely views of the South Devon Coast. It is beautifully situated in grounds of 19 acres. The gardens are very attractive, and there is a private road to the beach.

Resident Physicians: BERTHA M. MULES, M.D., B.S.; ANNIE S. MULES, M.R.C.S., L.R.C.P.
Telephone: Teignmouth 289.

THE COPPICE, NOTTINGHAM.
HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary and Temporary Patients received.

Tel.: 64117. *For terms, etc., apply to the Medical Superintendent.*

TYKEFORD ABBEY, NEWPORT PAGNELL,
BUCKS.
FUNCTIONAL NERVOUS DISORDERS, MEDICAL & CONVALESCENT CASES.

An approved Nursing Home for reception of Female Cases under the Mental Treatment Act.

The Home is a Mansion of Historical interest, standing in 9 acres of garden and grounds, and is situated 14 miles from Northampton, and 12 miles from Bedford on the main London to Northampton Road, fifty miles from London. Both sexes are accommodated. Psycho-Therapeutic Treatment is used extensively in suitable cases. Radiant Heat, X-Ray, and Ultra-violet Light. Diathermy and Foam Baths. Billiards, tennis, etc. Fees from five gns. per week.
Apply, Dr. D. E. M. DOUGLAS-MORRIS. *Telephone*: Newport, Pagnell 121.

A Private Mental Hospital for the Treatment and Care of Mental and Nervous Disorders in both sexes.

Now removed to:

CHISWICK HOUSE, PINNER, MIDDLESEX.

Telephone: PINNER 234.

A modern country house, 12 miles from Marble Arch, in beautiful and secluded grounds.

Fees from 10 guineas per week.

Voluntary Patients received for treatment.

Special provision for "Temporary" patients under the new Mental Treatment Act.

DOUGLAS MACAULAY, M.D., D.P.M.

BARNWOOD HOUSE,
GLOUCESTER.

A REGISTERED HOSPITAL for the CARE and TREATMENT of LADIES and GENTLEMEN suffering from NERVOUS and MENTAL DISORDERS. Within two miles of the G.W. Railway and L. M. & S. Railway Stations at Gloucester, the Hospital is easily accessible by rail from London and all parts of the United Kingdom. It is beautifully situated at the foot of the Cotswold Hills, and stands in its own grounds of over 280 acres. Voluntary boarders of both sexes are also received for treatment.

Special accommodation for Lady Voluntary Boarders is also provided at the MANOR HOUSE, which has its own private grounds and is entirely separate from the main Hospital.

For particulars as to terms, etc., apply to—
ARTHUR TOWNSEND, M.D., Medical Supt.
Telephone: No. 7 Barnwood.

ST. ALBANS, HERTS.

BETHLEM ROYAL HOSPITAL, for Nervous and Mental Disorders,

Monks Orchard, Monks Orchard Road, Eden Park, Beckenham, Kent.

Reg. Tel. Address: Bethlem, Beckenham. *Telephone*: Springpark 1180—1181.

Station: Eden Park (Southern Railway).

President: LORD WAKEFIELD OF HYTHE, C.B.E., LL.D.
Treasurer: SIR LIONEL FAUDEL-PHILLIPS, Bart.
Physician-Supt.: J. G. PORTER-PHILLIPS, M.D., F.R.C.P.

This Registered Hospital is now situated at Monks Orchard, in some 250 acres of park, pleasure, and farm grounds.
Applications can be considered on behalf of patients of the educated classes in a presumably curable condition.
With a view to early treatment voluntary or uncertified patients are admitted.
Patients who can contribute 5 guineas weekly towards the cost of treatment and maintenance may be received as vacancies arise. The Committee will also consider applications for admission at lower rates, and in certain cases will be prepared to admit patients free of charge.
Every facility for specialized investigation and treatment is provided in the Lord Wakefield Science and Treatment Unit. In this Unit is found the X-ray and Dental Departments and the Bio-Chemical, Pathological, and Psychological Laboratories.
Furthermore, provision is made for Electro-Therapy and Hydro-Therapy to be carried out in all their forms.
In addition to the Resident Medical Staff, Consultants in special branches of Medicine and Surgery are available whenever required.
The comfort of sensitive patients is greatly enhanced by the fact that the majority are given single bedrooms.
For forms and further particulars apply to the Physician-Superintendent at the Hospital.

RUTHIN CASTLE

(FORMERLY DUFF HOUSE, BANFF)

The first Private Hospital in the United Kingdom to be fully provided with a whole-time specially qualified Staff of Doctors, Analytical Chemists, Bacteriologists, Radiologists, Nurses, Dietists, Masseurs, and Masseuses, and full equipment of Laboratories, X-rays, Electrocardiographs, Artificial Sunlight, and Medical Baths.

The Hospital is equipped for the diagnosis and treatment of any form of ill-health, except Mental and Infectious Diseases. The fees are inclusive.

The climate is mild and the neighbourhood beautiful. Apply: The Secretary,

Telegrams: Castle Ruthin. Telephone: 66, Ruthin. Ruthin Castle, North Wales.

PECKHAM HOUSE, 112, Peckham Road, London, S.E.15.

Telegrams: "Alleviated, London." Telephone: Rodney 4741—4742.

The above House, which was established in 1826, is an Institution for the care and treatment of persons suffering from mental diseases and nervous disorders. Both certified patients and voluntary boarders are received. Separate houses for treatment and accommodation of special cases adjoin the Institution. There is a seaside branch, Kearsney Court, near Dover, to which patients may be sent for treatment or on holiday. Motor and carriage exercise is provided as required. Patients can avail themselves of a course of physical drill. Tennis courts. Entertainments, dances, and indoor amusements held throughout the year.
Illustrated prospectus and further particulars can be obtained from the Medical Superintendent.

UNIVERSITY of CAMBRIDGE.

DIPLOMA IN MEDICAL RADIOLOGY AND ELECTROLOGY.

The next Course of Study for the Diploma, which is open only to duly qualified Medical Men and Women, begins on October 5th, 1931, and occupies nine months.

During the first three months instruction in Physics is given in the Cavendish Laboratory, and in Elementary Radiology and Electrology in the Department of Radiology at Cambridge. Arrangements are made by the British Institute of Radiology for a similar Course to be given in London at the same time. These Courses are alternative.

The second three months must be spent in London, where lectures are given at the British Institute of Radiology, and are combined with clinical instruction in the large teaching Hospitals.

The third three months may be spent in recognized Hospitals in London or elsewhere, the student acting as clinical assistant or in similar capacity.

The examinations consist of three parts, viz.:

1. Physics, with examinations in January and April.
2. Radiology and Electrology, with examinations in April and July.
3. The presentation of a Thesis which is entirely the candidate's own work, and is intended to show that he has had practical experience of the subjects.

Further information as to the Courses, together with application forms for admission, may be obtained from:

G. STEAD, M.A., Secretary for the Diploma, Cavendish Laboratory, Cambridge, or,

The General Secretary, British Institute of Radiology, 32, Welbeck Street, London, W.1.

Completed forms of application for admission must reach the Secretaries not later than September 10th.

EPSOM COLLEGE.

(Established in 1855 as a Public School with a Royal Medical Foundation.)

NOTICE is hereby given that the ANNUAL GENERAL MEETING OF GOVERNORS will be held at the offices of the ROYAL COLLEGE OF PHYSICIANS, 12, Pall Mall East, S.W.1, on Friday, the 26th day of June, 1931, at 4 o'clock in the afternoon, when the result of the voting for Pensioners, Annuitants, and Foundation Scholars will be announced.

In accordance with the provisions of the Acts of Parliament, 10 members of the Council will retire at this meeting. It will be proposed that the following be re-elected for a further period of three years: Dr. J. W. CARR, C.B.E., Mr. F. S. FLEURET, LL.B., Dr. ROBERT A. GIBBONS, Mr. RANALD M. HANDFIELD-JONES, *M.C.*, Dr. OWEN LANKESTER, Dr ARNOLD LYNDON, O.B.E., Mr. SAMUEL OSBORN, J.P., and Dr. C. MCMORAN WILSON, *M.C.*; and that Mr. ARTHUR W. ORMOND C.B.E., be elected to fill a vacancy.

The Council will propose (*a*) that SIR FREDERIC G. HALLETT, Colonel NORMAN C. KING, and Mr. P. D. LEAKE be re-appointed Auditors for the ensuing year; and (*b*) that a slight modification in By-law 27 be made, particulars of which can be obtained at the office.

All voting papers must be returned to the office by the night of Saturday, June 20th, at latest, or the votes will be lost.

Notice is hereby given that an Extraordinary General Meeting of the Governors of Epsom College will be held at the offices of the Royal College of Physicians, 12, Pall Mall East, S.W.1, on Friday, the 26th day of June, 1931, at 4.15 o'clock in the afternoon, or so soon thereafter as the Annual General Meeting of the Governors of the College shall be concluded, for the purpose of considering and, if thought fit, passing the following resolution:

"That the Council of Epsom College be and is hereby authorised to promote legislation to amend, extend, and repeal the provisions of the Royal Medical Benevolent College Act, 1855, and the Royal Medical Benevolent College Act, 1894, so far as may be requisite or convenient for the following purposes, that is to say:

1. To effect the abolition of the present method of election of Pensioners, Foundation Scholars, and Annuitants by the Governors of the College, and to substitute therefor election of Pensioners, Foundation Scholars, and Annuitants by a Committee to be appointed by the Council, and to consist of twenty Governors, of whom ten shall be members of the Council and ten shall be Governors (not being members of the Council), whom the Council shall select annually as most adequately representing the varied interests of the Medical Profession.
2. To provide for the extension of the benefits of the charity so as:
   (*a*) To enable Pensions to be provided for Medical Women (but not for their widowers unless such widowers are otherwise eligible) on the same conditions as for Medical Men;
   (*b*) To render the sons of Medical Women eligible for election as Foundation Scholars on the same conditions as the sons of Medical Men; and
   (*c*) To enable Annuities or occasional pecuniary assistance to be provided for Medical Women or their families (but not for their widowers unless such widowers are otherwise eligible) on the same conditions as such annuities and assistance may be provided for Medical Men or their families.

By Order of the Council of Epsom College,
J. BERNARD LAMB, Secretary.

Office of Epsom College,
49, Bedford Square, London, W.C.1.
May 30th, 1931.

County of London.

The LONDON COUNTY COUNCIL invites applications for appointment as SENIOR ASSISTANT MEDICAL OFFICER at the MAUDSLEY HOSPITAL, Denmark Hill, S.E.5 (for Treatment of Incipient Mental Disorder). Candidates must be not more than 40 years of age (unless already in the Council's Mental Hospital Service), and must be registered to practise both in Medicine and Surgery in England. Appointment pensionable under the Asylums Officers Superannuation Act, 1909. Salary (under review) £650 a year, rising by annual increments of £30 to £740 a year. Charges made for board, lodging, etc. (at present £2 9s. weekly), if required to be resident. Application form (which gives full particulars) obtainable from Chief Officer (Ref. M.O.) L.C.C. Mental Hospitals Dept., Artillery House, Artillery Row, S.W.1. Canvassing disqualifies. Applications must be received by Thursday, June 11th.

MONTAGU H. COX,
Clerk of the London County Council.

UNIVERSITY OF LONDON.

EXTERNAL EXAMINERSHIPS, 1932.

The Senate announce the following vacant Examinerships for the year 1932.

For the First Examination for Medical Degrees.
GENERAL BIOLOGY. PHYSICS.

For the Second Examination for Medical Degrees.
PHYSIOLOGY (Two).

For Final and Higher Examinations for Medical Degrees.
FORENSIC MEDICINE AND HYGIENE (Two).
MENTAL DISEASES AND PSYCHOLOGY.
NEUROLOGY. PATHOLOGY.
TROPICAL MEDICINE.

Associate Examiners.

Applications will also be invited for Associate Examiners in Medicine, Obstetric Medicine, Pathology, and Surgery. A separate application form must be used for Associate Examinerships and the word "Associate" must be written on it.

Application form (or forms if more than one Examinership is applied for) and particulars of the remuneration and duties can be obtained from the External Registrar.

Candidates must send in their names to the External Registrar, GEO. F. GOODCHILD, M.A., B.Sc., with any attestation of their qualifications they may think desirable, on or before Monday, July 6th, 1931. (Envelopes should be marked "Examinership.")

The Senate desire that no application of any kind be made to individual members.

If testimonials are submitted one copy only of each is required. In no case should original testimonials be submitted. If more than one Examinership is applied for a separate and complete application must be forwarded in respect of each Examinership. The appointments will be made by the Senate in November. Applicants who desire that the result should be communicated to them are requested to enclose a stamped and addressed envelope with their applications.

University of London, EDWIN DELLER, Principal.
South Kensington, S.W.7.
June, 1931.

University of Leeds.

POST-GRADUATE COURSES IN OBSTETRICS AND ANTE-NATAL WORK AT THE LEEDS MATERNITY HOSPITAL.
(108 Beds.)

Registered Medical Practitioners are admitted to the Hospital Practice, comprising Ante-natal, Labour and Isolation Departments, for periods of 2—4 weeks.

For particulars as to vacancies at the University Obstetrics Students' Hostel, adjoining the Hospital, apply to the DEAN, School of Medicine, Leeds.

June 21st, 1930.

St. Mary's Hospital, Institute OF PATHOLOGY AND RESEARCH.

Principal: Sir ALMROTH E. WRIGHT.

Applications are invited from qualified Medical Practitioners for a RESEARCH STUDENTSHIP. This will be tenable for six months, and may be renewed for a second period of six months.

The Institute comprises the following departments: Anatomy and Embryology, Physiology, Pathology, Chemical Pathology, Clinical Bacteriology, Systematic Bacteriology, and Immunology.

The student, who will receive an honorarium at the rate of £200 per annum, may elect to carry out his researches in any one of these departments, and would be required to work under the direction of the head of the department concerned.

Preference will be given to old St. Mary's Students.

For further particulars apply to the Secretary, Institute of Pathology and Research, St. Mary's Hospital, Paddington, W.2, to whom applications must be sent not later than Tuesday, June 16th.

Rotherham Hospital.
(130 Beds.)

Wanted, CASUALTY HOUSE SURGEON (male), qualified. Salary £150, with board, residence, and laundry.

Applications, with copies of recent testimonials, to be sent to the Secretary, G. W. ROBERTS, 8, Moorgate Street, Rotherham.

Rotherham Hospital.
(130 Beds.)

Wanted, SENIOR HOUSE SURGEON (male), qualified. A knowledge of Eye work is desirable. Salary £200, with board, residence, and laundry.

Applications, with copies of recent testimonials, to be sent to the Secretary, G. W. ROBERTS, 8, Moorgate Street, Rotherham.

INDIAN MEDICAL SERVICE

Recruitment of European Officers.

Applications are invited from medical men for permanent commissions in H.M.'s Indian Medical Service. The terms offered include a gratuity of £1,000 on retirement after six years' service, or £2,500 after 12 years' service, together with free return passages, for those who no longer desire to remain in the Service. In other respects the terms will be as detailed below.

Candidates must be British subjects under 32 years of age at the time of application, and must be registered under the Medical Acts in force in Great Britain and Northern Ireland.

CAREERS.

The Indian Medical Service offers wide opportunities of medical experience, including clinical, preventive, specialist, and research work. At the beginning of his career an officer is employed on the military side, which has medical charge of the Indian Army. Promotion is on a time scale up to the rank of Lieutenant-Colonel, and by selection to the ranks of Colonel and Major-General. An officer may apply after one year's Indian service to have his name registered for transfer to the civil side, from which appointments are made to Civil Surgeoncies, which are established at the principal civil centres to provide for the medical needs of civil officials and for general medical administrative purposes; to specialist (for example, public health and bacteriological) services; to research posts; and to professorships at the Medical Schools.

NOTE.—It is not possible to state at present what, if any, prospects of employment on the civil side will be open to Indian Medical Service Officers under the proposed new constitution for India.

PAY.

The monthly rates of pay for European officers in the Service who have a "non-Asiatic" domicile are as follows:

Rank.	Service in Rank.	Basic Pay.	Overseas Pay.	Years of Total Service.
1	2	3	4	5
		Rs.	Rs.	
Lieut.	—	500	150	1st
			150	2nd
			150	3rd
Capt.	(i) During first 3 years' service as Captain	650	150	4th
			£15	5th
	(ii) With more than 3 and less than 6 yrs.' service as Captain	750	£15	6th
			£25	7th
			£25	8th
	(iii) With more than 6 years' service as Captain	850	£25	9th
			£25	10th
			£25	11th
			£30	12th
Major	(i) During first 3 years' service as Major	950		
	(ii) With more than 3 and less than 6 years' service as Major	1100		
	(iii) With more than 6 years' service as Major	1250		
Lieut.-Col.	(i) Until completion of 23 years' total service	1500	£30	13th and over
	(ii) During 24th and 25th years' service	1600		
	(iii) After completion of 25 years' total service	1700		
	(iv) When selected for increased pay	1850		

EXTRAS.—In addition to the above rates various allowances are admissible for a large number of special appointments on both the military and the civil side which may be held by members of the Indian Medical Service. Special high rates of pay are also attached to the numerous administrative appointments open to officers in both branches of the Service.

ANTEDATES IN COMMISSION.

Any service rendered by an officer during the war as a medical or combatant officer, or in a position usually filled by an officer, may be counted as service for increments of pay, promotion retirement and retired pay, but not for gratuity.

One half of any service in the ranks during the war may be counted as service for retirement and retired pay only.

Candidates possessing certain higher medical qualifications may be granted an antedate of one year in their commissions. Past service in certain hospital appointments may also render candidates eligible for an antedate of one year. Persons holding or about to hold resident posts at recognized hospitals may be seconded in those posts for a period not exceeding one year. The maximum period of antedate, secondment, or antedate and secondment combined, admissible under this paragraph, is limited to one year.

OUTFIT ALLOWANCE.

Officers on appointment will receive an outfit allowance of £50.

PRIVATE PRACTICE.

With the exception of Administrative Officers, military or civil, and officers holding certain special appointments, officers are not debarred from taking private practice, so long as it does not interfere with their proper duties.

LEAVE.

Leave can be taken at reasonable intervals, and adequate rates of leave pay are provided. Extra leave (known as study leave), which may not exceed 12 months in all during an officer's service, may be granted to officers desirous of pursuing special courses of study of a post-graduate nature. During such leave, study allowance, at present fixed at the rate of 12s. a day in the United Kingdom, £1 a day on the Continent of Europe, and £1 10s. a day in the United States of America, is granted to an officer in addition to ordinary rates of leave pay.

PENSIONS.

The rates of pension are as follows:

	Per annum. £
After 17 years' service for pension	400
,, 18 ,, ,, ,, ...	430
,, 19 ,, ,, ,, ...	460
,, 20 ,, ,, ,, ...	500
,, 21 ,, ,, ,, ...	540
,, 22 ,, ,, ,, ...	580
,, 23 ,, ,, ,, ...	620
,, 24 ,, ,, ,, ...	660
,, 25 ,, ,, ,, ...	700
,, 26 ,, ,, ,, ...	750
,, 27 ,, ,, ,, ...	800

These rates are subject to alteration on account of a rise or fall in the cost of living as compared with the year 1919 to an extent not exceeding 20 per cent. in all, the revision being undertaken triennially. With effect from July 1st, 1930, a reduction of 5¼ per cent. has been made on this account from the amounts shown.

There are additional pensions ranging from £65 to £350 per annum for officers who have held administrative appointments.

PASSAGES.

An officer on appointment is provided with free passage to India. The wives and families of officers who are married prior to the date of the officers' embarkation on first appointment will also be provided with free passage to India, subject to the payment of messing charges.

Officers and their families are also eligible for passage concessions under which they are granted a certain number of return passages home at Government expense during their service.

INSTRUCTION PRIOR TO EMBARKATION.

Officers are required to undergo courses of instruction at the Royal Army Medical College and at Aldershot, lasting approximately six months, prior to their embarkation for India on first appointment.

Full details regarding these appointments and forms of application may be obtained from the Under-Secretary of State for India, Military Department, India Office, London, S.W.1. The Selection Committee will meet at the India Office early in July next, and the selected candidates will be required to join a course of instruction commencing early in August, prior to sailing for India early in 1932. Applications should be submitted as soon as possible.

Salford Royal Hospital.
(263 Beds.)

Applications are invited for the following vacancies, which will occur in the Resident Medical Staff (male), on June 30th next:

BRYAN JEAFFRESON,
Hon. Secretary to Faculty.

County Council of Durham.

DISTRICT TUBERCULOSIS MEDICAL OFFICER.

The County Health Committee invite applications for a District Tuberculosis Medical Officer, at a commencing salary of £500 per annum, rising by annual increments of £25 to £700 per annum. Travelling expenses will be paid by the County Council.

The appointment will be held subject to three months' notice on either side, and to the following conditions:

(1) The officer appointed must be a registered Medical Practitioner between the ages of 25 and 45 years, must devote the whole of his time to the duties of the office, and must not engage in private practice.

(2) He should either have held a previous appointment as Tuberculosis Medical Officer, with the approval of the Minister of Health, or

(i) Have had at least three years' experience in the practice of his profession;

ii) Have spent in general clinical work a period of not less than eighteen months, of which not less than six months have been spent in a Hospital as Resident Officer in charge of beds occupied by general medical or surgical cases; and

(iii) Have received special training for a period of not less than six months in the diagnosis and treatment of Tuberculosis.

(3) He will be attached to the County Health Department, and will, subject to the directions of the County Medical Officer, be under the control of the Central Tuberculosis Medical Officer.

(4) He will be required to reside in his Dispensary area, or such other centre as required by the Council.

(5) He will be required to carry out the duties of a District Tuberculosis Medical Officer.

(6) He must be prepared, if called upon, to act as Locum Tenens to other members of the Medical Staff of the County Medical Officer.

(7) The holding of a Diploma in Public Health, and practical experience in Bacteriological Laboratory work, will be deemed additional qualifications for the post.

The candidate appointed will be required to pass the County Council's medical examination, and will be subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922.

Applications, endorsed "District Tuberculosis Medical Officer," and accompanied by copies of not more than three recent testimonials, must be addressed to the undersigned, and must be received by him not later than June 13th.

Shire Hall, C. FRANKS,
Durham. County Medical Officer.
May 23rd, 1931.

County Borough of Southampton

APPOINTMENT OF MEDICAL OFFICER OF HEALTH.

The Corporation invite applications for the position of Medical Officer of Health, Port Medical Officer, etc., for the County Borough at a salary of £1,250 per annum.

The gentleman appointed must not exceed 45 years of age, and must be experienced in all branches of Municipal Medical Service. He will be required to perform all duties prescribed by statute, and such other duties as the Council may from time to time assign to him.

He must devote the whole of his time to the office, and must not engage in private practice. and all fees or emoluments payable to or received by him must be paid to the Corporation.

The post is designated under the Local Government and Other Officers Superannuation Act, 1922, and the successful candidate will be required to undergo a medical examination.

The appointment, which will be terminable by three months' notice on either side, will be subject to the approval of the Minister of Health.

Forms of application can be obtained from the undersigned.

Applications on the proper form, accompanied by copies of not more than three recent testimonials, and endorsed "Medical Officer of Health," must be delivered at my office not later than June 17th.

Canvassing of members of the Council will be regarded as a disqualification.

R. RONALD H. MEGGESON.
Municipal Offices, Town Clerk.
Southampton, May, 1931.

The Royal Infirmary,

SUNDERLAND. (290 Beds.)

Wanted, beginning of June, HOUSE SURGEON (male). Salary £140 per annum, with board, residence, and laundry.

Applications, stating age, qualifications, and accompanied by copies of testimonials, to be sent to the undersigned.

S. C. FRYERS,
House Governor & Secretary.

Durham County Council and CHESTER-LE-STREET URBAN DISTRICT COUNCIL.

APPOINTMENT OF DISTRICT TUBERCULOSIS MEDICAL OFFICER AND MEDICAL OFFICER OF HEALTH (Male).

Applications are invited for the above appointments. Candidates must be registered in the Medical Register as holding a Diploma in Sanitary Science, Public Health, or State Medicine, and must have had a satisfactory experience in the diagnosis and treatment of Tuberculosis.

The salary will be £800 per annum, in the proportion of £572 15s. payable by the County Council, and £227 5s. payable by the Chester-le-Street Urban District Council.

The officer appointed must either have held a previous appointment as Tuberculosis Medical Officer, with the approval of the Minister of Health, or

(i) Have had at least three years' experience in the practice of his profession;

(ii) Have spent in general clinical work a period of not less than eighteen months, of which not less than six months have been spent in a Hospital as Resident Officer in charge of beds occupied by general medical and surgical cases; and

(iii) Have received special training for a period of not less than six months in the diagnosis and treatment of Tuberculosis.

Travelling and subsistence allowances according to scale will be paid by the County Council in respect of the duties of District Tuberculosis Medical Officer, and the officer will, subject to the directions of the County Medical Officer, be under the control of the Central Tuberculosis Medical Officer.

It will be a condition of the appointment that if either post is terminated, the other post will be automatically vacated.

The appointments will be subject to the approval of the Minister of Health; and the officer will not be permitted to take part in private practice.

The person appointed will be required to live in or near Chester-le-Street.

Applications, endorsed "T.M.O. and M.O.H.," and accompanied by copies of not more than three recent testimonials, must be addressed to the undersigned, and must be received by him not later than June 13th.

Shire Hall, C. FRANKS,
Durham. County Medical Officer.
May 23rd, 1931.

Surrey County Council.

ASSISTANT MEDICAL OFFICER.

Applications are invited for the appointment of an Assistant Medical Officer. Candidates must possess a qualification in Public Health, and have had experience in the Medical Inspection of School Children, Maternity and Child Welfare, and the treatment of Tuberculosis and Venereal Diseases. The officer appointed will be required to undertake such other public health duties as may be allocated to him. He will be on the staff of the County Medical Officer of Health, must reside in the County, and devote his whole time to the work. Salary £600 per annum, rising by annual increments of £20 to £700 per annum. Travelling expenses in accordance with the Council's scale will be allowed.

The appointment will be subject to the approval of the Ministry of Health, to the provisions of the Local Government and Other Officers Superannuation Act, 1922, and to the Standing Orders of the Council, which provide, inter alia, that appointments may be determined at any time by three months' notice.

Applications, stating age, qualifications, and experience, together with copies of three recent testimonials, should be made on the prescribed form and sent to the County Medical Officer of Health, County Hall, Kingston-upon-Thames, from whom copies of the application form may be obtained, and to whom any enquiries relating to the appointment should be addressed.

Last day of receipt of applications, Friday, June 19th. Canvassing, directly or indirectly, will disqualify.

County Hall, DUDLEY AUCKLAND,
Kingston-upon-Thames. Clerk of the
May 27th, 1931. County Council.

East Suffolk and Ipswich HOSPITAL, IPSWICH.

(265 Beds—7 Residents.)

Applications are invited for the post of CASUALTY OFFICER. Salary £120 per annum or more according to experience. Board, residence, and laundry.

Applications from British (male) candidates, stating age, qualifications, and experience, accompanied by three recent testimonials, to be sent to the undersigned.

The Hospital, ARTHUR GRIFFITHS,
Ipswich. Secretary.
June 1st, 1931.

Borough of Ilford.

APPOINTMENT OF ASSISTANT MEDICAL OFFICER OF HEALTH.

The Corporation invites applications from legally qualified Medical persons of both sexes for the office of Assistant Medical Officer of Health, for duties in connection with Maternity and Child Welfare work, School Medical Inspection, and General Public Health work. Candidates for the appointment must have had special experience in Midwifery and Ante-natal work since qualification, and subject to this, preference will be given to candidates who possess the Diploma of Public Health or similar qualification, and have had definite experience in Children's Diseases.

The commencing salary of the officer will be £600 per annum (no bonus), rising by one annual increment of £50, and two annual increments of £25, to £700 per annum.

The person appointed will be required to devote whole time to the duties of the office, to reside within easy distance of the Corporation's Maternity Home, and to enter into an agreement for the due performance and fulfilment of all the duties and conditions governing the appointment. The appointment will be subject to a satisfactory medical examination, and to the provisions of the Local Government and Other Officers Superannuation Act, 1922.

Applications, which must be made on forms obtainable (with list of duties) from the undersigned, accompanied by copies of three recent testimonials (which will not be returned), endorsed "Assistant Medical Officer of Health," must be received at my office, at the Town Hall, Ilford, not later than Friday, June 12th.

Canvassing members of the Council, directly or indirectly, is prohibited and will disqualify.

Town Hall, By Order,
Ilford. ADAM PARTINGTON,
June, 1931. Town Clerk.

Borough of Brighouse.

HIPPERHOLME URBAN DISTRICT COUNCIL.

HALIFAX RURAL DISTRICT COUNCIL.

H. AUBREY FROGGATT, Gen. Secretary.

Manchester Ear Hospital, GROSVENOR SQUARE, ALL SAINTS'.

The Board invite applications for the post of NON-RESIDENT HOUSE SURGEON. 24 beds. Salary at the rate of £150 per annum, with partial board. Candidates must be duly qualified and registered. Applications, with copies of four recent testimonials, to be forwarded to Mr. REGINALD S. MILFORD (Hon. Secretary, Manchester Ear Hospital), c/o Mr. W. J. ELLAM, 33, Brazennose Street, Manchester.

Scunthorpe and District War MEMORIAL HOSPITAL.
(82 Beds—Two Residents.)

Applications are invited for the post of SECOND RESIDENT SURGEON (male or female), with charge of Medical beds, to take up duties as early as possible. Salary at the rate of £150 per annum, with board, residence, and laundry. Candidates, who must possess registered qualifications, should forward applications, stating age, nationality, etc., together with copies of recent testimonials, to
ARTHUR E. MAW, Secretary.

Herzl Moser Hospital, LEOPOLD STREET, LEEDS.

RESIDENT MEDICAL OFFICER required immediately. Salary £100 per annum. Ample time for Post-graduate study. Apply Secretary as above.

City of Leeds.

GATEFORTH SANATORIUM.

Applications are invited from duly qualified and registered Medical Practitioners (male) for the post of RESIDENT MEDICAL OFFICER at the City of Leeds Sanatorium at Gateforth (50 beds). Applicants should have had previous Hospital and Sanatorium experience.

The successful candidate will be attached to the staff of the Tuberculosis Sanatorium at Killingbeck, and will work under the direction of the Medical Superintendent of that institution.

The salary will be at the rate of £450 per annum, rising by biennial increments of £25 to £550, together with board, residence, and laundry. The candidate appointed will be required to pass a medical examination and to contribute to the Superannuation Fund.

Schedule of duties and form of application may be obtained from the Medical Officer of Health, 12, Market Buildings, Vicar Lane, Leeds.

Applications, endorsed "Tuberculosis Officer," together with copies of three recent testimonials, should be delivered at the Town Clerk's Office, 26, Great George Street, Leeds, not later than 10 a.m. on Saturday, June 20th.

THOS. THORNTON,
Town Clerk.

Administrative County of ESSEX.

MALE ASSISTANT COUNTY MEDICAL OFFICER OF HEALTH.

The County Council of the Administrative County of Essex invite applications for the above post from registered Medical Practitioners holding a Diploma of Public Health, and not over 45 years of age.

The commencing salary attached to the appointment will be from £500 to £600 per annum, according to experience, and will rise by annual increments of £25 to £700 per annum. Travelling expenses will be paid by the Council.

The Local Government and Other Officers Superannuation Act, 1922, has been adopted by the County Council.

Applications on the prescribed form, obtainable from the undersigned, and accompanied by copies of not more than three testimonials, which will not be returned, should be addressed to me and delivered at the Shire Hall, Chelmsford, not later than 10 a.m. on Friday, June 12th.

Shire Hall, JOHN H. GOOLD,
Chelmsford. Clerk of the County Council.
May 23rd, 1931.

Liverpool Psychotherapeutic CLINIC,

56, Bedford Street North, LIVERPOOL.

Applications are invited for the post of Part-time MEDICAL REGISTRAR to the above Out-Patient Clinic, for a period of twelve months at a salary of £150 per annum.

Applicants must be registered Medical Practitioners, and preference will be given to those candidates who intend to specialise in Psychological Medicine.

The person appointed will be required to attend the Clinic for the equivalent of five half-days per week.

Further information may be obtained from the Senior Honorary Physician at the above address, and applications, marked "Medical Registrar," together with copies of recent testimonials, must be forwarded to the undersigned not later than June 25th.

W. O. HUNTER RODWELL,
Honorary Chairman.

Kent and Canterbury Hospital, CANTERBURY.

Applications are invited for the following posts:

HOUSE PHYSICIAN (male).
HOUSE SURGEON (male).

The salary payable in each appointment is at the rate of £125 per annum, plus board, residence, and laundry.

Applications, stating age and particulars of qualifications, and enclosing copies of testimonials, should be forwarded to the undersigned.

W. T. SOUTHWOOD.
Superintendent & Secretary.

The Willesden General Hospital (INCORPORATED), N.W.10.

CLINICAL ASSISTANT to the Surgical Out-patient Department (Monday afternoon).

Applications are invited for the above Honorary appointment for a period of six months from July 1st.

Applications must be received by the Secretary of the Hospital not later than first post on Thursday, June 18th, from whom details of the appointment may be obtained.

May 29th, 1931.

County Council of Middlesex.

RESIDENT ASSISTANT MEDICAL OFFICERS—REDHILL HOSPITAL, EDGWARE, and PARK ROYAL HOSPITAL, WILLESDEN.

The County Council invite applications for the positions of Resident Assistant Medical Officers at the Redhill Hospital, Edgware, and Park Royal Hospital, Willesden.

Candidates must be registered Medical Practitioners who have held resident appointments in a General Hospital. The officers appointed will work under the control of the Medical Superintendents, and will devote their whole time to their official duties.

Salary in the case of each appointment is at the rate of £400 per annum, rising by annual increments of £50 to £600 per annum, together with board, lodging, and laundry.

The successful candidates will be required to pass such medical examination as the County Council may direct, and, unless subject to the Poor Law Officers Superannuation Act, 1896, to contribute to the County Council's Superannuation Fund. The appointments will be held during the pleasure of the Council, and subject to one month's notice on either side.

Applications, stating (1) age, (2) qualifications, and (3) previous experience, together with copies of not more than three recent testimonials, must be received by the undersigned not later than June 20th.

No special application forms are provided. Envelopes must be endorsed "Resident Assistant Medical Officer."

Canvassing, directly or indirectly, will be a disqualification.

N.B.—Redhill Hospital is a modern General Hospital with accommodation for some 200 acute cases, and a similar number of patients at the adjoining Redhill Institution suffering from chronic disease are under the care of the Medical Staff of the Hospital. Park Royal Hospital provides accommodation for over 600 acute and chronic cases.

ERNEST S. W. HART,
Clerk of the County Council.
Middlesex Guildhall, Westminster, S.W.1.
June 2nd, 1931.

Rhondda Urban District COUNCIL.

TEMPORARY ASSISTANT MEDICAL OFFICER.

The above Council invite applications from registered Medical Practitioners to act as whole-time Temporary Assistant Medical Officer of Health and Assistant School Medical Officer, under the direction, supervision, and control of the Council's Medical Officer of Health, at a salary of £500, rising by annual increments of £25 to £700 a year, together with travelling expenses necessarily incurred in the performance of the duties.

Candidates must have had not less than three years' professional experience subsequent to registration, and the possession of a Diploma in Public Health is desirable.

The duties will pertain to both Public Health and School Medical Services, but experience in the work of school clinics, including the examination and certification of defective children, orthopaedic work, X-ray and ultra-violet radiation, and general anaesthesia for dental and throat operations, will be considered to be of special importance.

The appointment, which will be terminable by two calendar months' notice on either side, will be subject to the approval of the Board of Education, and the officer appointed will be required to reside within the Rhondda Urban District, and will not be allowed to engage in private practice.

Applications are to be made on forms obtainable from the Medical Officer of Health, Tydfil House, Llewelyn Street, Pentre, Rhondda, by whom they must be received, endorsed "Temporary Assistant Medical Officer," and accompanied by copies of three recent testimonials, not later than the first post on Tuesday, June 16th.

The Council Offices, D. J. JONES,
Pentre, Rhondda. Clerk of the Council.
June 2nd, 1931.

Swansea General and Eye HOSPITAL. (316 Beds.)

To the Medical Profession.

4 and 5, Adam Street,
London, W.C.2.

Dear Sir,

Owing to the steady and rapid increase in my Medical and Dental Agency Business (which I have carried on for over fifty years, with the able assistance during the last twelve years of my Son, Leslie H. Turner), I have found it necessary to secure further competent assistance.

I have much pleasure in announcing that I have been fortunate in securing the co-operation of Mr. Herbert Needes, of 31, Bedford Street, W.C.2, who has successfully carried on for some years the Agency first established by his Father in 1860. During this period I have been intimately acquainted with Mr. Needes, and as from June, 1931, Mr. Needes will remove his offices to 4 and 5, Adam Street, and hopes to meet his clients there whenever they require his services. Mr. Needes' terms of business are identical with mine and are similar to those of all the old-established Agents, and will be found as reasonable as possible, having regard to the best interests of our respective clients. We hope that anyone requiring services that we can render them will not hesitate to consult us as heretofore. I have also been fortunate in securing the services of another experienced Accountant, Mr. A. Hogan, for many years engaged in that capacity in H.M. Service. I might add that our Agency will at all times be conducted in strict confidence.

Yours faithfully,

PERCIVAL TURNER.

THE OLDEST AND LEADING MEDICAL AGENT.

Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges.

1. SOUTH COAST TOWN.—PARTNERSHIP.—A one-third share (with increase later) is offered in a mainly better-class non-panel Practice. Average gross cash receipts for the past three years £4,150. Fees from 10/6. Not much midwifery. Well-situated house, with 3 reception, 8 bedrooms, etc. Can be rented on lease at £135 p.a. Premium 2 years' purchase.
2. MIDDLESEX.—Steadily increasing middle and working-class PRACTICE, producing this year at the rate of £800. Panel of 250. Fees from 5/-. House contains 2 reception, 4 bedrooms, etc. Price for freehold £1,650, part on mortgage. Premium £850.
3. WITHIN 20 MILES OF LONDON (WEST).—Well-established rapidly increasing PRACTICE, in very pleasant growing residential district, offering excellent future prospects. Cash receipts last year £1,700, including small panel of 150. No dispensing. Visits 5/- upwards; mids. from 4 gns., about 40 cases. Good house (3 reception, 5 bedrooms, etc.), in half an acre of garden, with tennis court. Garage. Price, freehold, £1,850. Premium £2,100. Cottage Hospital. Ill health reason for selling.
4. ESSEX.—Very old-established PRACTICE, situated in pleasant country district, in growing area about 30 miles from London, and few miles from the sea. Cash receipts average nearly £900 p.a., including panel of 600. House contains surgery and waiting room, 3 reception, 5 bedrooms, bathroom, etc. Garden. Garage. Gas, but electric light available. Moderate rental. Premium 1½ years' purchase.
5. LONDON, EAST.—Very old-established working-class PRACTICE averaging for past twelve months over £2,300, including panel of over 2,800. Good appts. worth nearly £160. Visits from 2/6. Very low expenses. Suitable house can be rented or purchased. Central surgery can be rented. Premium £4,250.
6. LONDON, WEST.—Old-established good middle-class PRACTICE, averaging over £2,500 p.a. (last year £2,600), medium-sized panel. Visits 5/- to 10/6 and occasionally 21/-. Midwifery discouraged; 2 or 3 cases yearly at 15 to 20 gns. House contains professional accommodation, 2 reception, 5 bedrooms, dressing rooms, etc. Leasehold (23 years to run at nominal ground rent). Price £1,650. Premium £4,475.
7. WEST MIDLANDS.—Old-established PRACTICE, in small country town, in very picturesque surroundings, averaging over £1,200 p.a. (last year £1,500). Panel of about 700. Fees from 5/6. Centrally situated house, with 2 reception, 5 bedrooms, etc. Rent on lease £90 p.a. Good sport and schools. Premium £2,000.
8. NORTH DEVON AND CORNWALL BORDERS.—Very old-established unopposed Country PRACTICE, in beautiful district near the coast. Cash receipts average just over £1,100 p.a., including appt. and panel of 330. Suitable house available. Premium £1,600, to include drugs, etc. Hunting, golf, fishing, tennis, etc.
9. MIDLANDS.—COUNTY TOWN.—PARTNERSHIP.—A one-fourth share is offered in an exceptionally sound good mixed-class Practice, averaging over £6,000 p.a., including panel of 3,400. Lowest fee 4/-. Very little midwifery. If single, purchaser can live in comfortable rooms; otherwise choice of houses for sale, or on rental. Premium 2 years' purchase.
10. PARTNERSHIP.—YORKSHIRE.—LARGE CITY.—A one-third share with succession to the whole Practice in about one year's time, is offered in a rapidly increasing PRACTICE, producing for the last 12 months approximately £2,300, including panel of 1,500. One appt. worth £150. A suitable house will be vacant shortly. Premium £1,200. Large scope for further development.
11. LONDON, N.W. (Kentish Town area).—In a well-populated district a mainly working-class PRACTICE, producing for 12 months ending March last £728, including panel of 260. House contains 10 rooms; small garden; garage. Rent £120 p.a. on lease. Premium £900.
12. LONDON (WEST END).—Old-established non-dispensary and non-panel PRACTICE, averaging over £4,700 p.a. Visits (very few) and consultations from one guinea upwards. No midwifery. Suitable accommodation available on rental. Premium £6,000. Good introduction given. Personal application desired.
13. LANCS.—LARGE TOWN.—PARTNERSHIP.—A one-third or two-fifths share is for disposal in well-established and increasing middle and working-class Practice. Gross cash receipts for immediate past 12 months £3,150. Panel of over 3,000. Appts. worth about £80 p.a. Fees from 2/6. Choice of two houses, both at moderate rentals. Premium only 1½ years' purchase.
14. WITHIN 20 MILES OF LONDON (WEST).—Rapidly developing district.—PARTNERSHIP.—A half share in a well-established good middle-class Practice, averaging over £3,500 p.a. Panel of 1,100 and appts. worth £100 p.a. Fees 3/6 to 21/-. Good corner house, with 3 reception, 6 bedrooms, etc. Garden. Price for freehold £2,100. Premium 2 years' purchase.
15. SURREY.—COUNTRY PRACTICE.—Very old-established, and situated in delightful district. Gross cash receipts for past 12 months £2,000, including panel of about 700. Fees from 2/6 to 21/-. Midwifery 3 to 20 gns. Exceptionally nice house, with 2 reception, 6 bedrooms, and professional rooms. Nearly 2 acres of garden. Price for Practice and house £5,000.
16. CHESHIRE.—NEAR COAST.—Old-established good mixed-class PRACTICE, averaging for the past 3 years nearly £1,600, including panel of 1,283. Very good house in 3 acres of ground, with 2 reception, 4 bedrooms, etc. Rent on lease £85 p.a. Premium £2,300.
17. PARTNERSHIP.—HOME COUNTY.—Within 40 miles.—In a small country town, in very pleasant district, the third share, with increase later, of an old-established mixed-class Practice offering good scope. Cash receipts average over £3,000 p.a., including panel nearly 1,700 and appts. Good house, with 3/4 of an acre of garden, tennis court, etc. Rent on lease £65 p.a. Premium £1,700. Ingoing partner should be about 30, English or Scotch, and pref. married.
18. WITHIN 30 MILES OF LONDON.—In a delightful residential district (well populated and growing rapidly), a small PRACTICE, producing last year £406, including panel of 300, and capable of considerable development. Very good residence (suitable for resident patients) in about 2 acres of ground. Price, freehold, £4,000. Mortgage arranged. Premium £400. Excellent schools, good society, and sport.
19. FAVOURITE COAST TOWN.—Old-established good middle and better-class PRACTICE, producing over £1,800 p.a. Selected panel of under 400. Fees 5/6 to 10/6. Very little midwifery. Commodious house, with 2 reception, 6 bedrooms, etc. large garden. Freehold for sale. Premium £3,000.
20. SOUTH OF ENGLAND.—Pleasant Town near sea coast.—Very old-established PRACTICE (partly Surgical), averaging over £2,400 p.a. (last year £2,516), including panel of 500. Centrally situated house. Price for Practice and house £5,000. Successor should also have some knowledge of Eye, Ear, Nose, and Throat work.
21. HOME COUNTIES.—Within 40 minutes' run of London.—Old-established mixed-class and increasing PRACTICE, situated in small town with pleasant surroundings. Cash receipts average £1,725 p.a., including appt. £70 and panel 1,000. House with good accommodation and small garden. Price for freehold £2,500. Premium 1½ years' purchase. Educational facilities.
22. SOUTH AFRICA.—Within 8 hours of Durban.—Rapidly increasing PRACTICE in very pretty township near sea coast, producing last financial year over £1,700, including appt. £120. Practically all fees, which are good, are paid in cash. Opposition negligible. Bungalow residence in about one acre of ground. Rent £84 on lease. Premium £1,500, to include furniture, drugs, instruments, and motor car (£1,325 without latter), payable £1,000 down and balance by easy instalments. Excellent climate and sport.
23. NORTH WALES.—PARTNERSHIP.—A one-third share is offered in a good mixed-class Practice producing over £1,700 p.a., including panel of 470 and appts. of about £100 p.a. Fees 5/6 to 21/-. Purchaser, if bachelor, could reside with Vendor. Good sport and schools. Premium 2 years' purchase.
24. SURREY.—Increasing residential district, with good train service to town.—Well-established good general PRACTICE, offering Surgical scope. Gross cash receipts for last 12 months nearly £3,200, with panel of about 900. Visits 5/- to 21/-. Suitable house, with 3 reception, 7 bedrooms, etc. Can be bought or rented on lease. Premium 1½ years' purchase.
25. SOUTH CORNWALL.—Near Sea.—Well-established PRACTICE producing about £700 p.a., including panel of over 600. Fees 5/- to 21/-. Suitable house, with 3 reception, 5 bedrooms, etc. Rent on lease £50 p.a. Good sport and mild climate. Premium only 1 year's purchase. Ill-health reason of sale.
26. LONDON, SOUTH-EAST.—Woman Doctor's PRACTICE, producing £560 immediate past 12 months. Panel of 152. Fees 2/6 to 21/-. Suitable flat can be rented at £60 p.a. Premium £650, or near offer. Very good scope for increase.
27. NORTH LINCS.—COAST TOWN.—Old-established PRACTICE, producing last year nearly £2,900 p.a., including panel of 1,700. Fees 5/6 to 21/-. Practically unopposed. Good modern house, with special professional rooms. Nice garden. Garage. Freehold for sale, part on mortgage. Good sport and schools within reach. Premium 1½ years' purchase.
28. NORTH OF ENGLAND.—GOOD TOWN.—A one-third share is offered in a very sound PRACTICE averaging about £5,000 p.a. Ingoing partner must be well qualified, not over 35, and interested in medicine. Suitable house available. Premium 2 years' purchase.
29. NEAR HEREFORDSHIRE BORDER.—A one-third to one-half share in a well-established good-class non-dispensing PRACTICE, producing about £1,800 p.a. Panel of over 500. Good house can be rented at £60 p.a. Spot of all kinds. Premium 1½ years' purchase, part by instalments. Welsh not necessary.
30. CHESHIRE.—COAST TOWN, within reach of Liverpool.—Well-established PRACTICE, averaging over £1,200 p.a., including panel of 780. Fees from 3/6. Mid. 2 to 5 gns. Double-fronted house, with 3 reception, 4 bedrooms, etc. Price for freehold £1,200, £800 on mortgage. Premium £1,100 for quick sale.
31. SOUTH-WESTERN COUNTY. — Hospital Town. — Good mixed-class PRACTICE, averaging £839 p.a., including small panel of 140, and appt. worth £40 p.a. Visits 5/- to 10/6. Not much midwifery. House, with 3 reception, 4 bedrooms, etc. Garden. Garage. Price for freehold £1,600, half on mortgage. Very good schools and sport. Premium £1,300.
32. MIDLANDS.—COUNTY TOWN.—Old-established better-class PRACTICE, averaging £793 p.a. and offering good scope. Panel 500. Fees 5/- upwards. Well situated house with good garden, with 3 reception, 4 bedrooms, etc. Separate Surgery. Rent on lease £111 p.a. Premium 1½ years' purchase.

Full Schedule of Terms and Conditions will be forwarded on application.

Printed and published by the British Medical Association, at their Office, Tavistock Square, in the Parish of St. Pancras, in the County of London.

COAGULEN-CIBA IN HAEMORRHAGE

Five correspondents in *The British Medical Journal*, July 28th, 1928, p. 182, testify to the value of Coagulen-Ciba in Haemophilia.

Reports on the successful administration of Coagulen-Ciba were published in *The Lancet*, October 31st, 1925, p. 918, Intestinal Haemorrhage; *The Lancet*, June 13th, 1925, p. 1238, Haemoptysis treated by Intrapulmonary Injections; *The Lancet*, January 24th, 1925, p. 176, Haemorrhage following Tonsillectomy.

Three cases (two Haemoptysis, one Bowel Haemorrhage) successfully treated with Coagulen-Ciba by the mouth are reported in the *Journal of the Royal Naval Medical Service*, No. 1, Vol. XII, pp. 64-65.

Full particulars and reports to Physicians on request.

THE CLAYTON ANILINE CO., LTD., Pharmaceutical Department, 40, Southwark Street, LONDON, S.E.1.

BRITISH BRITISH

Elastoplast

(Patent 253,527)

THE ORIGINAL & FINEST ELASTIC PLASTER

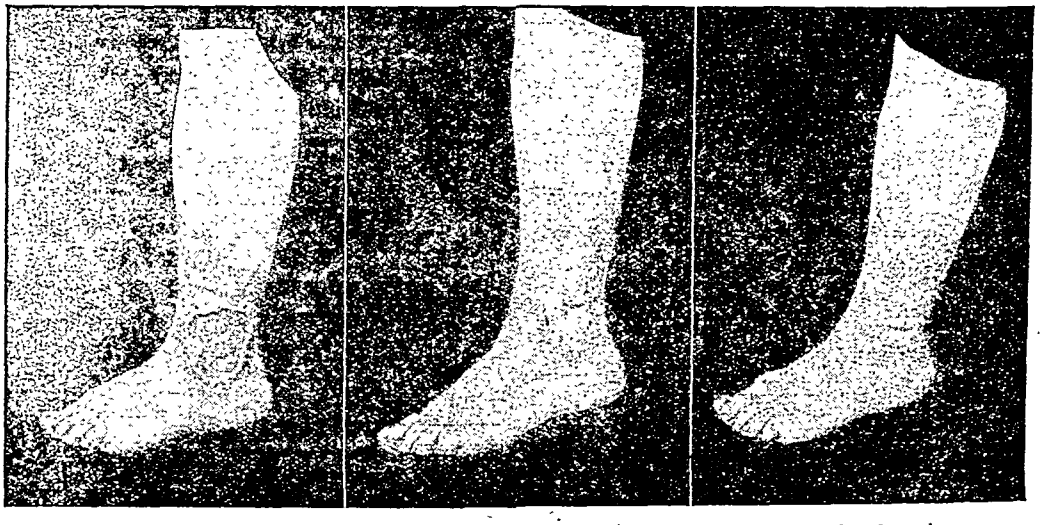
The cure of Varicose Ulcer by means of Elastoplast Bandages is now practised in nearly every Hospital in the British Isles, and 100% cure of cases is achieved.

In certain cases of Varicose Veins where, on account of systemic disease, or the patient's timidity, a curative course of injection cannot be given, then the veins can be kept obliterated by Elastoplast.

Elastoplast is also extensively used for general surgical and orthopaedic work.

As a support for varicose veins, sprains, strains, dislocations, after-treatment of fractures, weak joints, flat or dropped foot, etc., Elastoplast is unequalled.

Manufactured from the finest yarns, Elastoplast is the only Elastic Plaster having the correct degree of elasticity, thus ensuring perfect compression and support.



Woman patient aged 55. After 12 weeks' treatment. After a further 2 weeks.

The only treatment consisted of Elastoplast Bandages, changed weekly at first, and later fortnightly.

Other Elastoplast Specialities include:—Finger Dressings, Wound Squares, Wound Strips, Boil Dressings, Eye Dressings, Vaccination Dressings, etc., all on the pliable Elastoplast base, with medicated pads. Elastoplast will reduce your Dressings Accounts, save you valuable time, increase the efficiency of the injured person, and, moreover, ensure cleanliness. Also—VISCOPASTE BANDAGES (improved Unna's Paste Type), Adhesive Gelatine Bandages.

Literature and cuttings will be sent on application, or a trial set containing full Bandages and a range of Dressings upon receipt of P.O. value 2/6 (Overseas postage extra) by the manufacturers:

T. J. SMITH & NEPHEW, Ltd.

HULL. LONDON. GLASGOW. MANCHESTER.

Enquiries to—Dept. B, 42, Tavistock Square, London, W.C.1.

ELASTOPLAST MAY BE OBTAINED FROM YOUR USUAL SURGICAL SUPPLY HOUSE.

Printed and published by the British Medical Association, at their Office, Tavistock Square, in the Parish of St. Pancras, in the County of London.

WITH SUPPLEMENT

No. 3675 SATURDAY, JUNE 13, 1931 Price 1/3

THE AVOIDANCE OF ACID STATES

Many athletic individuals leading active and, according to the usual standards, healthy lives, yet experience early degeneration of the arterial walls, apparently induced by disturbances of ideal acid-base relations. The very activity of their exercise involves the formation of excess acids, which, if not promptly eliminated, inevitably cause structural injury.

A regular morning draught of Eno's "Fruit Salt" promotes elimination, and lowers the acidity of the urine. This effervescent saline, being composed entirely of alkaline salts and of combinations of fruit acids which, when absorbed, act as alkalinising agents, tends both directly and indirectly to restore the normal blood reaction.

The ENO "Medical Reminders." The Proprietors of ENO'S "Fruit Salt" will appreciate the opportunity of sending, free of charge, to any member of the Medical Profession a copy of any of the following:—

"The Doctor's Pocket Remembrancer"
"The Practitioner's Pocket Book"
"The Panel Doctor's Pocket Book"
"The Doctor's Emergency Reminder"
"Urgent Abdominal Diagnostics"

FORGING AHEAD

Nearly 10,000,000 consumers in the British Isles regularly use gas.

Scores of thousands of up-to-date new houses are having gas laid on. During 1930 more than 161,000 gas points were fitted in some 29,000 new houses by one gas undertaking alone.

3,000 trades use gas. Birmingham, Sheffield, and Coventry manufacturers alone require more than 7,000,000,000 cubic feet each year.

In 1912 the annual consumption of gas in the British Isles was 210,000,000,000 cubic feet. The 1930 returns show an output of nearly 330,000,000,000 cubic feet.

THE GAS INDUSTRY IS FORGING AHEAD.

The B.C.G.A., representing the British Gas Industry, is at your service for free information and advice on any use of Gas. A letter to the Secretary of this Association will receive prompt and careful attention.

GAS THE FUEL OF THE PRESENT THE FUEL OF THE FUTURE

THE BRITISH COMMERCIAL GAS ASSOCIATION, 28, GROSVENOR GARDENS, LONDON, S.W.1.

How many cases of *food poisoning* will you come across this Summer?

You can cure—but refrigeration would prevent them. And to you and yours, at any rate, refrigeration is available in its most advanced, and most practical form—Frigidaire. For a trifling payment that you would never miss each month, you can assure to yourself and your family the benefits of clean, pure, *fresh* food. Food that actually tastes better—for the simple reason that all its flavour and freshness are kept intact. Why not send in the coupon below and see how little you need pay?

Frigidaire incorporates all the conveniences and refinements that you would wish to have in your electric refrigerator. Here are just a few of them:—

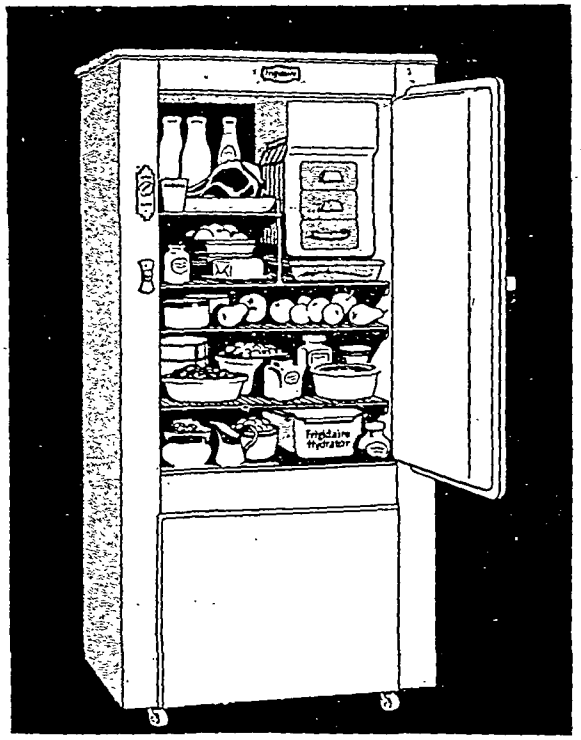
The Quickube Ice Tray, enabling single cubes, or many, or all, to be extracted at once, simply by a light pressure of the finger. No melting them out under the tap. Your cocktail ice is ready at a moment's notice. This is an exclusive Frigidaire feature.

•

The Cold Control, by which the freezing of ice cubes or any other frozen delicacy can be accelerated at will.

•

The automatic feature of Frigidaire is invaluable. The safety of your food does not depend on a maid's vigilance. Frigidaire maintains a dry cold that is *always* under 50°—the only safe temperature for food.



Practical, flat top, makes a useful shelf.

•

The Hydrator—a moist cold compartment for fresh vegetables, sandwiches, etc., etc. Even wilted vegetables will regain their crispness here in a few hours.

•

Ease of installation. A Frigidaire only needs connection with your electric supply. No plumbing is necessary.

•

Frigidaire Cabinets are all white porcelain-on-steel—the finest durable finish it is possible to have. And easily kept clean by just a rub with a damp cloth.

•

The new Frigidaire is quiet—you can't hear it start, stop or run.

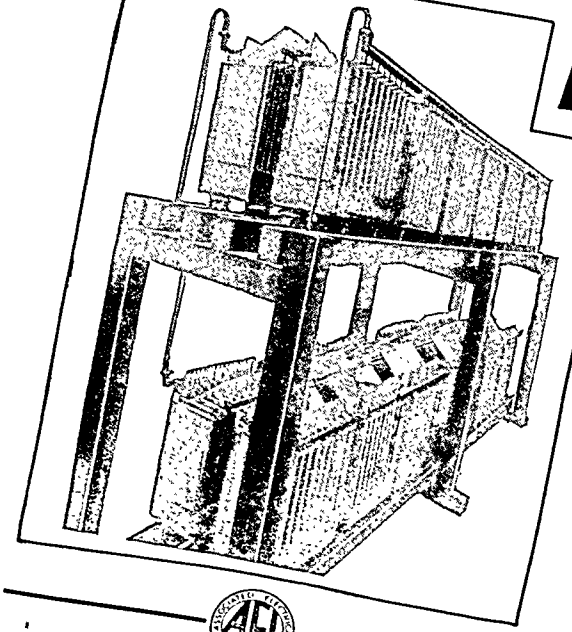
LODGE PLUGS LTD., RUGBY



When a life is at stake....

The psychological moment has arrived. Will the operation be successful? . . . Can modern science triumph over such disease? . . . The surgeon bends closer over the table . . . deft fingers touching slender instruments . . . a life is at stake . . . if the lights should fail, plunging the theatre into darkness . . .

Nowhere is reliable light supply more important than in operating theatres. A light failure may have far-reaching consequences. Every hospital should be equipped with Ediswan Stationary Battery. Then if current fails, a switch over to the Ediswan saves the situation and restores light almost immediately.

The Ediswan Stationary Battery for Emergency Lighting is compact and robust. It takes up little space and is sturdily built to give long service. Running costs are almost negligible. Installation costs are low.

May we co-operate with you in evolving a Battery specially to suit your requirements?

Salt and Son Ltd.

1793 1931

The Years Between

One hundred and thirty-eight years have come and gone since the House of Salt was first established.

During this period Salt's have kept in close co-operation with the Medical Profession, and have been actively interested in the advances of Modern Surgery.

A unique reputation has been established for supplying every type of Surgical Appliance—specially made with absolute precision to each individual case and strictly in accordance with the attending Practitioner's prescription.

It is through these methods that

SALT'S
SURGICAL APPLIANCES

have earned the commendation of numbers of leading Medical Men.

The Ideal Laxative

REGULOL

REGD.

IT is a highly palatable Emulsion of Liquid Paraffin with Agar-Agar, possessing all the advantages of the former without its objectionable qualities, and forming probably the best possible remedy for Chronic Constipation in Children and Adults.

"Regulol" is available in two forms: "PLAIN" or "COMPOUND." The latter is a combination with Phenolphthalein 4 grains per oz., and is indicated in more acute forms of Constipation where the simple lubricating effect of Paraffin is insufficient.

SAMPLE 1-lb. JAR FREE ON REQUEST.

Please indicate whether Plain or Compound is required.

(This offer is limited to the British Isles.)

TO COUNTER ACIDOSIS

As SALVITAE contains 59% of Potassii et Sodii Citro-Tartras and 30% of Sodii Sulphas it is of great value both in maintaining health and in the treatment of disease, through eliminating deleterious nitrogenous products and favourably influencing circulation, glandular secretions, peristalsis, and metabolism.

The fruit acids of SALVITAE are converted in the system into potentially basic alkaline carbonates, thus enabling the blood to keep the uric acid compounds in solution, and facilitate their removal.

An Efficient Oral Antiseptic Need Not be Disagreeable to the Taste

Too often the use of an oral antiseptic is associated in the patient's mind with a disagreeable taste. That such an antiseptic need lack nothing in efficacy, whilst being pleasant in taste, is most forcibly proved in the instance of Odol Mouthwash.

Experiments and the experiences of medical men in the past with Odol have proved it to be a most efficient bactericide. In addition, it is absolutely harmless and cannot in any way injure the most delicate mucous membrane of the mouth.

In prescribing Odol Mouthwash doctors will obtain the desired results in a way most pleasant to the patient.

". . . . we must go further back than the antenatal period, and ensure a supply of healthy mothers by watching women from the neonatal period of life to maturity."

The serious mortality among women (8,000 die annually from causes traceable directly or indirectly to childbirth) was dealt with at a recent Ingleby Lecture; it was pointed out that although antenatal treatment is of definite importance the vital point is that "*very often in the antenatal period it is too late to deal effectually with antecedent affections in early life which have seriously handicapped a woman's reproductive capacity*" (*Lancet*, May 30th, 1931, p. 1171).

In other words, it is necessary to take the "long view" by safeguarding the equipment of the child still in embryo, thus ensuring a future generation of healthy mothers.

It was stated further that "*the anti-infective action of Vitamin A and the influence of Vitamin D on the calcium metabolism make it imperative that pregnant women in the antenatal period should be provided with foodstuffs rich in these substances*" in order that, apart from the benefit the mother will derive from the availability of a sufficiency of these essential factors, the growing foetus may have its needs met also for the purposes of its healthy and normal growth and the building up of its resistive power.

Radiostoleum, by providing accurately-standardised amounts of vitamins A and D for the absorption by the foetus during the neonatal period, provides in part a solution of the problem of the mortality of the next generation of mothers.

ASSIMILATION IS RAPID—EFFORTLESS

with these stimulating essences

UNIQUE, stimulating, and restorative properties combined with rapid and effortless assimilation have made Brand's Essences of Beef or Chicken famous for nearly a century.

Recent scientific tests show these essences can be digested forty minutes quicker than ordinary foods, without formation of residue. They restore vitality with the least possible strain to digestive organs.

In the treatment of specific fevers, in disorders associated with pyrexia, in intestinal disturbances, and before and after operations, 99 out of every 100 doctors interviewed find them indispensable.

Prepared by an exclusive process from finest English meats, non-irritating, deliciously palatable, these essences are particularly suitable for convalescents, especially in cases of anorexia.

Samples will be gladly sent on receipt of a professional card, Dept. F.35, Brand & Co. Ltd., Mayfair Works, South Lambeth Road, London, S.W.8.

VICHY-CÉLESTINS

And the other State Springs of Vichy.

FERMENTATIVE DYSPEPSIA.

When the secretion is vitiated in quality, and the motricity of the stomach weakens, that organ dilates, and the gastric stagnation allows the micro-organisms of many ferments to develop. Quite a series of acids are then to be met with (butyric, lactic, acetic, etc.), which not only irritate the mucosa, but further, after their passage into the intestine, become absorbed by the lymphatics and swept into the circulation. **Vichy-Célestins,** by its slightly stimulating action, clears out the stomach, and this avoids stagnation and consequent fermentation. As, in addition to doing this, it modifies stomachal metabolism, the secretions return little by little to their normal physiological condition.

CAUTION.—Each bottle from the STATE SPRINGS bears a neck label with the word "VICHY-ETAT" and the name of the SOLE AGENTS:

OVALTINE

FOR THE AGED

"Ovaltine" is delicious sustenance for old people. It sustains life ideally by giving tone to the tissues and promoting the healthy activity of the bodily functions. "Ovaltine" provides complete nourishment in easily assimilable form. Its use greatly increases the nourishing value of other foods. The digestibility of milk, for instance, so largely used in old age, is increased two-fold by adding "Ovaltine" to it, while the starch in the cereals is converted into easily assimilated malt sugar by the enzyme diastase which "Ovaltine" contains in abundance.

"Ovaltine" is purin-free. Its use, therefore, neither aggravates, nor favours the accumulation of uric acid in the system, nor leads to kidney disorder or gout. The tendency to constipation, so common in old age, is avoided by the use of "Ovaltine."

"Ovaltine" replaces to great advantage the usual meal-time beverages, tea and coffee, which are valueless as sources of nourishment and often contraindicated in senility.

A liberal supply for clinical trial sent free on request.

EVANS'

EVANS SONS LESCHER & WEBB LTD.

Sometimes

a major operation . . .

YOU have many patients in whom coffee-drinking is a habit so consuming and so ingrained that prohibiting it is in the nature of a major operation on the patient's nervous system. Without coffee, their appetite may be diminished, and the temptation to take a cup or two may be well-nigh irresistible.

But now there is a pleasant, sure way to protect your patients from an overdose of caffein without prohibiting coffee . . . good coffee . . . rich coffee . . . satisfying coffee—and that way is to prescribe H.A.G. COFFEE.

And that you may satisfy yourself how fully the effects of caffein have been minimized in H.A.G. Coffee, make the night-test. Send the coupon below for a liberal sample of H.A.G. Coffee. When it arrives, give it this convincing test: drink your first cup of it at night. It won't keep you awake. Next morning you'll know, from actual experience, that patients can enjoy H.A.G. Coffee without fear of caffein effect.

A perfect blend of finest coffees

H.A.G. Coffee is all coffee—nothing but coffee—a delightful blend of the choicest Central and South American coffees. The decaffeinization process takes place before the coffee beans are roasted, leaving undisturbed the spicy flavour, the fragrant aroma—everything that makes coffee "the beloved beverage."

This is scarcely less important than the fact that the effects of caffein have been minimized. For, as you will discover, the delicious flavour of H.A.G. Coffee transforms the order to give up coffee, because of its caffein, from a test of the patient's will-power into a daily delight.

Your grocer stocks H.A.G. Coffee—ground or in the bean and in vacuum tins that preserve its freshness and its fragrance. Or send the coupon below for a liberal sample tin of H.A.G. Coffee. With it we shall be pleased to send a copy of "Some observations of the Action of Caffeine," a more complete discussion of H.A.G. Coffee. Send the coupon now.

BRITISH BRITISH

Elastoplast

(Patent 253,527)

THE ORIGINAL & FINEST ELASTIC PLASTER

The cure of Varicose Ulcer by means of Elastoplast Bandages is now practised in nearly every Hospital in the British Isles, and 100% cure of cases is achieved.

In certain cases of Varicose Veins where on account of systemic disease, or the patient's timidity, a curative course of injection cannot be given, then the veins can be kept obliterated by Elastoplast.

Elastoplast is also extensively used for general surgical and orthopaedic work.

As a support for varicose veins, sprains, *strains, dislocations, after-treatment of* fractures, weak joints, flat or dropped foot, etc., Elastoplast is unequalled.

Manufactured from the finest yarns, Elastoplast is the only Elastic Plaster having the correct degree of elasticity, thus ensuring perfect compression and support.

Woman patient aged 55. After 12 weeks' treatment. After a further 2 weeks.

The only treatment consisted of Elastoplast Bandages, changed weekly at first, and later fortnightly.

Other Elastoplast Specialities include:—Finger Dressings, Wound Squares, Wound Strips, Boil Dressings, Eye Dressings, Vaccination Dressings, etc., all on the pliable Elastoplast base, with medicated [illegible] ll reduce your Dressings Accounts, save you valuable time, increa[illegible] njured person, and, moreover, ensure cleanliness. A Lecture
ON
THE CAUSATION OF STONE IN INDIA*

BY
ROBERT McCARRISON, C.I.E., M.D., D.Sc.,
HON. LL.D., F.R.C.P.
HONORARY PHYSICIAN TO THE KING; COLONEL, INDIAN MEDICAL SERVICE; DIRECTOR, NUTRITIONAL RESEARCH, INDIAN RESEARCH FUND ASSOCIATION

Urinary calculus is very prevalent in India. From reports, for which I am indebted to civil surgeons, it appears that, during the years 1926–28, 34,325 persons were found to be suffering from the disease; or 1 in 10,000 of the population. These represent the combined records for three years, and relate only to persons seeking medical relief; but when it is remembered that hospital patients form but a relatively small fraction of the people of India, and that hospitals and dispensaries are but sparsely distributed, it may safely be assumed that the disease is more prevalent than these figures indicate.

The incidence of stone varies greatly in different parts of the peninsula; it is so prevalent in some localities that they are known as "stone-areas," while in others it is rare or unknown. The prevalent belief that India in general *is a land of "stone"* is erroneous: parts are; others are not. Thus, taking the above figures as our index of its prevalence, we find such variations as the following:

Cases per 100,000 of Population

In India generally	10
In Dera Ghazi Khan (Punjab)	438
In Hyderabad (Sind)	266
In Sukkur (Sind)...	156
In Manipur (Assam)	84
In Dera Ismail Khan (N.W.F.P.)	62
In Saharanpur (U.P.)	25
In Ahmednagar (Lower Bombay)	13
In Benares (U.P.)...	5
In Sylhet (Assam)	2.8
In Malabar (Madras)	0.3
In Kolaba (Lower Bombay)	0

Of the 34,325 sufferers from stone, 16,384, or approximately 1 in 20,000 of the population, had their stones removed at operation. I have taken this figure as my index of incidence and prepared the spot map (Fig. 1). Each spot represents one stone removed at operation per 100,000 of the population of the particular district in which the patients lived. This map affords a fair indication of the distribution of the malady. It will be noted that the great "stone-area" of India extends from Sind, the North-West Frontier Province, and the Punjab into the western parts of the United Provinces. As we pass eastward towards Bengal and Assam the prevalence of the disease gradually diminishes; similarly, it diminishes towards the south and south-east until in the southern parts of the Bombay Presidency, Mysore, Hyderabad, and Madras the malady is relatively rare. It is relatively rare also in Burma. No reports were received from the greater part of Baluchistan, which abuts on Sind, and in which there is reason to believe the disease is also common; nor from Kathiawar, nor Travancore in the south. But these lacunae do not influence the general result, which, from the point of view of the investigator, is a significant one. It is that there are local factors which exercise a profound influence on the occurrence or non-occurrence of the malady. These influences may be geological, orographical, climatic, racial, nutritional, or microbic.

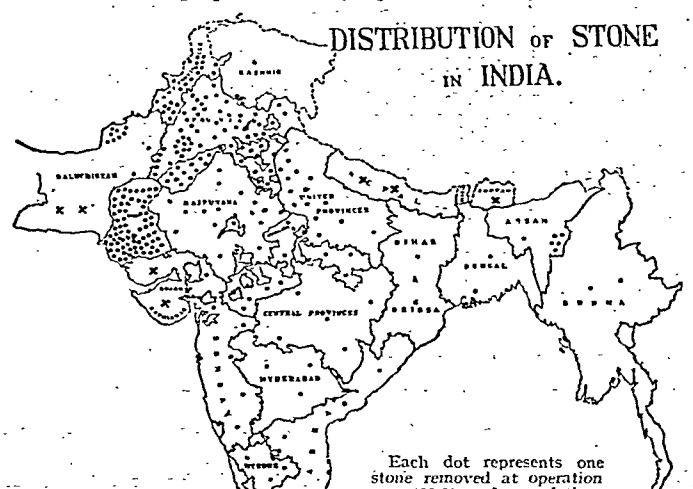

FIG. 1

GEOLOGICAL INFLUENCES

Urinary calculus occurs for the most part on soils of the Post-Tertiary Period; indeed, a map of the geological features of India shows a great post-tertiary band extending eastward from the Kirthar, Sulaiman, and Hindu Khush Mountains on the west and north through the cultivated plains of sub-Himalayan India to Bengal and Assam; and comprising the great plains of the Indus, the Thar or Indian Desert, regions eastward of "the five rivers" (Punjab), and the plains of the Ganges and its tributaries. It is in these plains that the great majority of all urinary calculi occur. At first sight one might be inclined to attribute significance to this association with Post-Tertiary rocks. But closer scrutiny of our data shows that no great importance can be attached to it, since it is in the plains of the Indus, and not in those of the Ganges, that the great majority of calculi occur.

OROGRAPHICAL INFLUENCES

Stone is most common in the plains of Northern India, but by no means confined to them. Far up in the [illegible] ranges of Dardistan, and throughout the Hindu Kush lands it also. In Chitral and Gilgit, in Gilgit, I have, in my early days, performed many operations for the relief of the condition—conscious even of the temporary nature of the relief I was affording. Stone is not related in any conspicuous [illegible] physical features of the country.

CLIMATIC INFLUENCES

It is most frequent in hot, arid, desert plains, where vegetation is relatively scanty; where grazing for cattle is poor, and scorched by the intense heat, or parched because of scanty rainfall. But its incidence is not always greater in these localities than in others more favourably situated. Thus it occurs with great intensity in the cultivated lands, watered by the five rivers of the Punjab and by the numerous Himalayan streams that go to swell the waters of the Ganges. Nor does rainfall appear to be a factor of importance: in Dera Ismail Khan (N.W.F.P. that furnace of the plains—where the rainfall is ra

more than 5 inches throughout the year, the incidence of stone is 62 per 100,000 of the population, as compared with 84 in Manipur (Assam), where the rainfall is 100 inches, or thereabouts, and vegetation plentiful. One thing the western and eastern areas of the great stone-belt have to some extent in common: a great disparity between summer and winter, and between day and night, temperatures. But here again too much importance can be attached to this fact. It has been suggested that, because of the known effect of hypervitaminosis-D in causing stone in rats, the constant exposure of a large part of the body to the rays of the tropical sun may induce in natives of India a condition of hypervitaminosis-D, conducive to stone formation. Experiments on albino rats have not, in my hands, lent support to this view. Further, the exposure is greater in the loin-clad southerner than in the more completely clad northerner.

RACIAL INFLUENCES

It is stated in certain monographs on "stone" that Mohammedans in India are more subject to it than Hindus; and it has been suggested that this is due to the Mussulman's habit of micturating in the squatting position, which renders complete evacuation of the bladder impossible. I have no data regarding the frequency of this habit in the two communities, though it would seem to be practised by both; but whether it be true or not that the Mussulman is more addicted to it than the Hindu, my data provide no evidence that stone is more common in the one community than in the other. In my series there are 1,024 cases in which particulars are given as to the community of the sufferer: of these, 757, or 73.9 per cent., were Hindus; 235, or 22.9 per cent., were Mohammedans; and 32, or 3.1 per cent., were in other communities.

Hindus form, approximately, 69.5 per cent. of India's 320 million people; Mohammedans 21.3 per cent., and other communities 9.2 per cent.—percentages which, so far as the two main communities are concerned, are practically identical with the percentage distribution of stone. Mohammedans are therefore no more subject to the malady than Hindus. If anything, other communities are more afflicted by it than either. The disease appears to be comparatively rare among Europeans in India; in my series they formed 0.44 per cent. of the whole.

NUTRITIONAL INFLUENCES

It is in the plains of the Indus, and in the sub-Himalayan regions fed by the upper reaches of the Ganges and its tributaries, that wheat is most grown. Here, too, the cultivation of maize is considerable; while in Sind the chief crop is millet. As we pass eastward along the Gangetic plain the cultivation of rice increases, reaching its acme in the Delta; southward, also, through Lower Bombay to Malabar and Madras, and south-eastward to the deltas of the Godaveri and Kistna Rivers, the cultivation of rice increases. In Burma, too, rice is the principal, and often the only, cereal produced. In these places rice is the staple article of diet. The suspicion thus arose in my mind that the gradual decline in the incidence of stone, from regions where wheat is the principal cereal grown to those where rice is the chief crop, might be associated in some way with the cereal forming the staple article of diet of the people. Experiments on animals showed that this was so. Groups of young albino rats were fed on a diet of the same composition but in which the cereal, forming 90 per cent. of the diet, differed. It was found that cereal foods ranged themselves in the following descending order of stone-producing potency: whole-wheat flour, oatmeal, North Indian millet (*bajra*), white flour, rice, and South Indian millet (*cambu*). The result of this experiment provided a partial explanation of the peculiar distribution of stone: its great frequency in the wheat-growing areas of the north-west, and its relative infrequency in the rice-growing areas of the south and east. But this association is not invariable. Thus, stone is as common, even commoner, among the rice-eating Manipuris (Assam) as in the wheat-eaters of Dera Ismail Khan (N.W.F.P.). There is more in the occurrence of stone than the cereal which happens to be the staple food in this or that part of India: other dietetic factors are concerned. What these factors are has been revealed, in some part at least, by experiment on animals.

EXPERIMENTAL PRODUCTION OF STONE

Well-fed albino rats do not suffer, certainly not in Coonoor, from stone; and these animals are very suitable for experimental work on this disease. I have used them throughout my own work. My first experiment was begun early in 1926. It lasted 157 days. Such experiments are tedious; the more so when one's object is to ascertain the faults in Indian dietaries to which "stone" might be attributable. The diet used consisted of oatmeal 53 parts, linseed meal 20 parts, cornflour 25 parts, calcium phosphate 1 part, sodium chloride 1 part, and distilled water *ad libitum*. It may be wondered why I used oatmeal, since it does not enter to any considerable extent into the dietaries of the Indian people. I confess at once that chance determined my use of it—a lucky circumstance such as occasionally comes the way of the investigator, and for which he must ever be on the watch. The original object of the experiment was not to produce stone but to learn the effect on the thyroid gland of an iodine-poor diet such as this one was. But as things turned out the experiment taught me three things: (1) that the so-called iodine-poor diet did not cause thyroid enlargement; (2) that it did cause stone and its sequelae; and (3) that it also caused a very grave form of anaemia, which subsequent investigation in my laboratory by Dr. Lucy Wills showed to be due to *Bartonella muris* carried by the lice with which my rats were infested.

Here I may pause to draw attention to this last, and very instructive, result: an anaemia which is brought about in practically cent. per cent. of rats by removal of the spleen is also brought about by a faulty food deficient in certain vitamins. The intact spleen protects against this anaemia; and the conclusion is irresistible that the faulty food, by its action on the pulp cells of this organ, reduces its protective action against *Bartonella muris*. This is a very noteworthy instance of the effect of faulty nutrition in breaking down the defences of the body against infection.

But to return to stone. The above diet caused the disease in 21 out of 120 animals, an incidence of 17.5 per cent. In my next experiment one group of young rats was fed on the same diet as the above, and another on a diet wherein the oatmeal was replaced by whole-wheat flour. This experiment also lasted for many days, and when at length it was completed it revealed a significant difference in the incidence of stone in the two groups: of the 50 rats fed on the "oatmeal diet" 4, or 8 per cent., had stone and its sequelae; of the 50 fed on the "whole-wheat diet" 11, or 22 per cent., had stone and its sequelae. Whole-wheat flour was thus shown to be more potent to cause calculus than oatmeal. The next problem which naturally occurred to me was whether the other ingredients of the diet were also factors of importance: these ingredients were cornflour and linseed meal. A further tedious series of experiments was undertaken from which the knowledge emerged that neither of these food materials contained any positive or toxic agent which was concerned in stone production. It further emerged that diets composed exclusively of white flour or of white bread, either

with or without added yeast or marmite, were also capable of causing stone, though the stone-producing potency of white flour was markedly less than that of whole-wheat flour; vitamin B deficiency was not concerned in causing stone. Subsequent experiments excluded another factor—deficiency of suitable protein.

Cereal foods thus appeared to vary in their stone-producing potency, and the experiment, mention of which I have made already, was undertaken to determine their relative degrees of potency. This experiment fixed them in the following descending order: whole-wheat flour, millet grown in the north of India, white flour, rice, and millet grown in the south of India. The last did not cause "stone" at all within the 515 days of the experiment. The significance of this observation in regard to the distribution of stone in India has already been referred to. Here another possibility arises: millet grown in one part of India may be stone-producing, while that grown in another may not: soil, manure, and irrigation conditions—which I had already shown to be capable of causing variations in the nutritive quality of food grains (McCarrison, 1926–28)—may thus be concerned in the production of stone. I have not so far been able to investigate this aspect of the matter.

The next step in my investigations was to see whether, by further additions to the stone-producing diet, the malady could be prevented. One group of rats was therefore fed on a diet of known stone-producing potency; another on the same diet to which whole milk was added, the milk being given in the proportion of two-thirds of an ounce per rat per day. Stone and its sequelae—cystitis, hydronephrosis, and pyonephrosis—were completely prevented by this measure. Clearly, therefore, milk contained "something" which counteracted the stone-producing action of the diet. Further experiments of a like kind followed, but in these the substance added was butter or cod-liver oil, the action of which was compared with that of vegetable oils in common use in India. The butter prevented stone, so also did cod-liver oil; the vegetable oils did not. This narrowed the issue down to deficiency of vitamin A bearing ingredients as a chief food fault concerned in stone production.

By this time I had become acquainted with the original observations of Osborne and Mendel (1917), associating urinary calculus with deficiency of vitamin A in rats fed on synthetic diets, and with the latter work of Fujimaki (1926), definitely demonstrating the specificity of vitamin A deficiency in this regard. With this help my work proceeded more rapidly, but along the lines previously followed: the production of stone by means of foods in common use by the people of India.

It was stated in some of the reports which I received from civil surgeons, as well as in textbooks on the subject, that hard waters have something to do with the causation of stone. Accordingly, lime was added to diets deficient, among other things, in vitamin A, with the result that the incidence of calculus, of cystitis, of hydronephrosis, and of pyonephrosis was greatly increased; and it was found that calcium-phosphorus imbalance was a further, and very important, factor concerned in the causation of certain types of urinary calculi.

The types of stones produced in these experiments were four: ammonium-magnesium-phosphate, calcium carbonate, calcium hydroxide, and stones composed of a mixture of calcium carbonate and calcium hydroxide.

My immediate object had thus been attained. It had been shown that certain food materials in common use by the people of India were capable of causing stone in rats when used in quantities disproportionate to certain other food materials that are antagonistic to stone formation.

INDIAN DIETARIES AND STONE

In India stone is a poor man's disease. Throughout the peninsula the staple article of diet of the people is one cereal grain or another. We have seen that these cereals vary in their stone-producing potency, and it may be assumed that all cereals contain, in some degree of concentration, a *positive agent* or agents favourable to stone formation. This assumption is justified by the observation that the stone-producing potency of whole-wheat flour is greater than that of white flour—something favourable to stone production is in part removed from the whole wheat in the process of manufacturing white flour; this "something" can scarcely be vitamin A, while we know it is not any of the other vitamins. (Here it may be suggested that the lesser potency of white flour as a stone-producing agent may be correlated with the gradual diminution of vesical calculus in England during the last fifty years—a period coinciding with the introduction and almost universal use of white flour.) We have seen also that the distribution of stone in India can be correlated with the kind of cereals in use in various parts of India; and we have seen, further, that milk and butter, if used in sufficient quantity, afford complete protection against stone in rats. Now the great fault of all Indian dietaries among the poorer classes, who are the chief victims of stone, is that their diets do not contain anything like enough milk and milk products, and I postulate that according to the kind and quality of the cereal grain they use as the staple of their dietaries, and according to the poverty of these dietaries in milk and the products of milk, so they will be more or less likely to suffer from stone. Milk and the products of milk are among the greatest of India's needs at the present time. I do not contend that this is the whole story; indeed, I know it is not, but it represents certain chapters of it.

DIETETIC FACTORS CAUSING STONE

There appear, therefore, to be two categories of dietetic factors concerned in stone formation: (*a*) *positive factors*, including excess of lime in the diet, and some unknown agent present in whole cereal grains; and (*b*) *negative factors*, including deficiency of vitamin A derived from animal sources, and deficiency of phosphates relative to the amount of lime in the diet. I say "vitamin A derived from animal sources," because millions of people in India are dependent for their supply of this factor—whatever that factor implies—on vegetables; I am not yet certain that the latter source of vitamin A is, from the point of view of stone prevention, as good as the former. I do not think it is, and I notice that de Langen (1929) of the Dutch Indies is of a like opinion.

Here it is necessary to make my position clear in regard to the value of whole-wheat flour and oatmeal as articles of diet. Because I have found that whole-wheat flour and oatmeal, when they compose the major part of an imbalanced diet, are stone-producing, this is not to say that I desire to displace these two most valuable foods from the high place in the dietaries of mankind to which they have attained throughout the centuries. To do so would be to doubt the evidence of one's own eyes, and to fly in the face of reason. Who that has seen the magnificent physique of the Sikh or Pathan would dare to recommend them to change their staple diet of unleavened whole-wheat bread for the white loaf of commerce? And who that has seen the slum children at Miss Margaret McMillan's "Nursery School" at Deptford can doubt that she was right to exercise the care she did in the selection of the oatmeal on which experience had taught her to rely as a constituent of her children's dietaries—children who rarely need the dentist? The truth is that

no single food material is in itself a "complete food"—even milk is not; if it be not faulty in one regard it is faulty in another. The best are those whose faults are least; and in the latter category both whole-wheat flour and oatmeal are to be included. Milk, as an exclusive food, will cause anaemia in rats; onions, anaemia in dogs; cabbage, goitre in rabbits; and oatmeal or atta will cause stone in rats; yet what better food can there be for mankind than a judicious mixture of all four? Animal experimentation has its uses—its great uses—but like every other instrument employed by man the results of its use must be judged by reason and experience.

STONE: A DISEASE OF FAULTY NUTRITION

During the course of my experimental work I have produced stone in 250 animals. The young rats that I

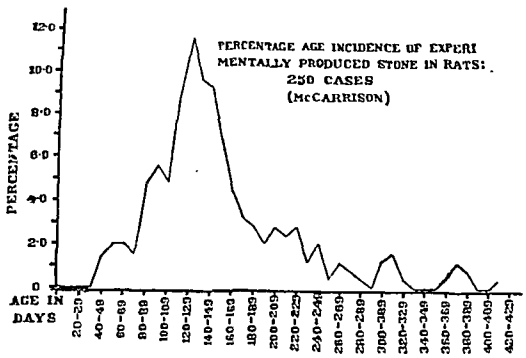

FIG. 2.

have used have always been about a month old at the outset of the experiments: that is to say, of an age at which they are able to fend for themselves, and are no longer dependent on maternal nutriment. They would correspond approximately to children of a year or two old. I have grouped these cases together in the chart which I now show you (Fig. 2). You will observe that in rats "stone" is a disease of early life; that the pinnacle of age incidence is reached when they are about 120 days old, when they have been living on the stone-producing diets for about 90 days. Thereafter the curve of age

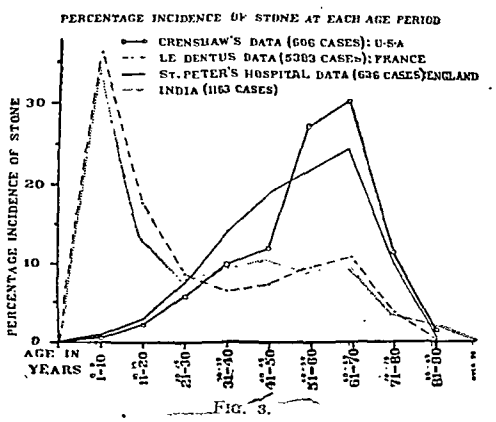

FIG. 3.

incidence declines rapidly and gradually fades away until, at the age of 400 days or over, stone is relatively rare. Now compare this curve, first with that of the age distribution of stone in India (Fig. 3). The same rapid rise will be noticed during its earlier stages, the same rapid fall and its gradual fading away thereafter; the curves in the rat and in the Indian are practically identical. Taking these facts into consideration with those I have already presented the conclusions seem to me to be irresistible that in India urinary calculus is a disease of faulty nutrition, and that the same food faults which produce the malady in rats produce it also in the people of India.

But it is not always so. In my next illustration (Fig. 3) I have set out in the same diagram the percentage incidence of stone at each age period as it is found in India, in France, in the United States of America, and in England. Here the incidence curves are of orders so different as forcibly to suggest that while the chief causes of stone in India and in France are probably the same—nutritional in the main—those in England and the United States of America are in the main different: in the one the high peak of incidence is at the earlier period of life, when nutritional disturbances are most likely to be felt; in the other it is at the other end of life. Many factors may account for stone production in later life: stone formed in early life may be endured to later life; stagnation of urine due to enlarged prostate and the like may cause it, or infection. But it is not my purpose to discuss the causation of stone in later life—a condition relatively rare in India.

SEX INCIDENCE OF STONE

In India stone is much commoner in males than in females: in my series the proportion is as 13.2 to 1. In children under the age of 15 years, 92.5 per cent. of stones occurred in males. My observations in this regard are in conformity with those of Winsbury White (1929)—

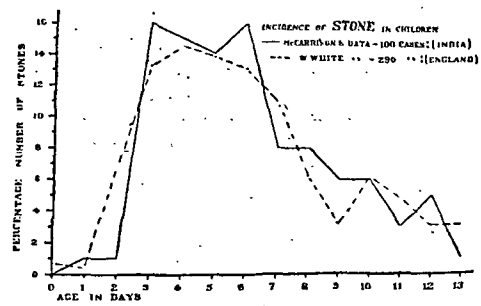

FIG. 4.

in fact his curve and my own are practically identical (Fig. 4); and if I be correct in my contention that in Indian children stone is a disease of faulty nutrition it is very likely to be so also in English children. One point of interest is brought out in this diagram (Fig. 4): the Indian curve shows that very occasionally stone may occur in breast-fed infants.

The greater incidence of stone in males does not apply to experimentally produced stone in rats. In these animals it is slightly more common in females. I have, at present, no explanation to offer of this difference in the two species.

INCIDENCE OF RENAL CALCULUS IN INDIA

In comparison with vesical calculus renal calculus is relatively rare in India (Fig. 5). In a series of 454 cases of stone recently sent to me by surgeons practising in parts of India where the disease is common, there were only 34 renal stones; a proportion of vesical to renal of 13.5 to 1. Whereas vesical calculus is pre-eminently a disease of early life, renal calculus is a disease of middle life (Fig. 5). In the course of my experimental work I have had frequent examples of renal calculus in rats. In my series of 250 experimentally produced stones there were 31 renal calculi; a proportion of vesical to renal of

8 to 1. In albino rats renal stone is equally common in the two sexes. In human beings it is much commoner in males.

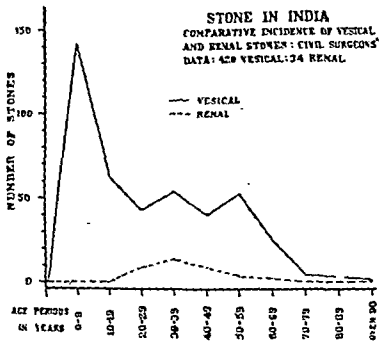

FIG. 5.

INCIDENCE OF URETERAL STONE IN INDIA

Ureteral stone is rare in India, or it is rarely operated upon. Among the 16,384 calculi removed during the years 1926–28 there were only 14 ureteral stones. A diagnosis of stone in the ureter was made in other cases, but the patients refused operation.

In my series of 250 experimentally produced stones in rats there were 21 examples of ureteral calculus: in the majority of these the stone was obviously on its way from the kidney to the bladder, and was not impacted in the ureter. Males had such ureteral stones more often than females (16 to 5).

CYSTITIS, INCRUSTED CYSTITIS, PYONEPHROSIS, ETC.

It is not possible, in the time at my disposal, to do more than mention the morbid states of the urinary tract so often associated with stone in experimental animals: cystitis, incrusted cystitis, hydronephrosis, and pyonephrosis. Any of these may occur without stone formation, though such occurrence is the exception and not the rule. We do not, as yet, know why one animal develops stone while another fed on the same diet develops incrusted cystitis or pyonephrosis without stone. Cystitis is not a necessary precursor of stone, even when the stone is of the ammonium-magnesium-phosphate variety. And cystitis without stone can be produced in rats with considerable certainty by diets deficient in vitamin A but containing an excess of animal protein—a combination of food faults not uncommon in human sufferers from cystitis. Curiously enough the cystitis so produced is commoner in female than in male rats: I believe I am right in saying that in human beings cystitis is also commoner in the female sex.

CHEMICAL COMPOSITION OF HUMAN STONES

During the past three years analyses of 226 human urinary calculi have been made in my laboratory (Newcomb and Ranganathan). The stones may be classified according to their chemical composition as follows:

	Number	Percentage of total number of stones
Pure uric acid	15	6.63
Pure oxalate	13	5.75
Pure phosphate	3	1.32
Phosphate-oxalate	23	10.17
Urate-phosphate	20	8.85
Urate-oxalate	78	34.51
Urate-oxalate-phosphate	74	32.74
Total	226	99.97

According to Kahn (quoted by Kauffmann) (1929), pure uric acid calculi are rare: they formed 6.6 per cent. of the total in our series of 226. Freyer (1908) found that most of the stones containing uric acid or urates occurred in young people. Our data do not confirm this observation. He also found that 64 per cent. of his Indian stones contained either uric acid or urates; our figure is higher: 82 per cent. He noted also that calcium oxalate calculi were commoner in adults than in children: in our series the average age of sufferers from pure oxalate stones was 29 years. Pfister has called attention to the predominance of oxalate stones in Egypt and in India; in our series of 226 there were 13 pure oxalate stones (5.75 per cent.), while 83.17 per cent. contained more or less oxalate.

Our analyses of kidney stones are relatively few, but they show that in India these stones consist mostly of calcium oxalate and not of uric acid or urates: an observation in conformity with that of Benjamin Moore (1911) and of Rosenbloom (1915); and in opposition to that of Stengel and Fox (1927). It would seem from the literature on this subject that renal calculi are generally considered to be composed of uric acid: this is not our experience in India.

Much difference of opinion exists as to the chemical composition of the nuclei of stones. It is not always easy to find the nucleus of a stone, or, when one has found it, to be sure that one is dealing only with the nucleus. One of my assistants (Mr. Ranganathan, 1930) has recently gone into the matter in some detail. He found that uric acid or urates formed the chief constituents of the nuclei, phosphates occurring only in traces; and that the composition of the nuclei did not always run parallel with that of the stones containing them, though an approximate parallelism existed in some cases.

There is a general belief that it is possible, from the physical characters of a stone, to make a good guess at its chemical composition. We do not find that this is so; such guesses are in general very inaccurate (Newcomb and Ranganathan, 1930).

So far as our analyses of human stones go it would seem that no particular kind of stone is more prevalent in one part of India than another. We have not found it possible, from the incomplete dietetic histories of sufferers, to correlate the chemical composition of calculi with that of the diets eaten by the people from whom they were removed: the great majority of their dietaries had, however, one fault in common—insufficiency of vitamin A bearing ingredients.

CHEMICAL COMPOSITIONS OF RAT STONES

As previously stated the stones produced in rats were of four varieties: ammonium-magnesium-phosphate, calcium carbonate, calcium hydroxide, and a mixture of the last two. The essential difference between them and human stones is the complete absence of uric acid or urates. Excluding traces of urates (forming less than 5 per cent. of the total ingredients) uric acid or urates occur in 82 per cent. of all human stones in India. The usual explanation given for the absence of uric acid in rat stones (as well as in those of cattle) is that these animals possess the power to oxidize approximately 80 per cent. of the circulating purines to allantoin. Allantoin is several times more soluble in water than is uric acid, and hence it never forms a constituent either of rat or of cattle stones. Human beings do not possess this power, and in them the degradation of purine bodies stops short at uric acid; and, as uric acid is very sparingly soluble in water, it is almost always found to be a constituent of urinary calculi in man (Swift Joly).

POWER OF THE URINE TO RETAIN URIC ACID IN SOLUTION

Urine varies greatly in its power to dissolve uric acid and retain it in solution. We have recently found that the urine of rats fed on purely vegetable diets retains

much more uric acid in solution than that of animals fed on diets containing large amounts of animal protein. Hindhede has, I believe, made a similar observation in man. The urine of rats fed on a diet of liver was capable of dissolving only a very little uric acid, and this was thrown out of solution after standing for twenty-four hours. The composition of the diet, by influencing the capacity of urine to hold uric acid in solution, may thus have a bearing on stone formation.

CHEMICAL COMPOSITION OF CATTLE STONES

Cattle stones, as we find them in India, are usually small, round, shot-like bodies, having, when fresh, a light or deep golden-yellow sheen. They may occur in large numbers (Fig. 6) in the same animal, and their usual location is the urethra. They are made up of thin layers, like the coats of an onion, all layers being of the

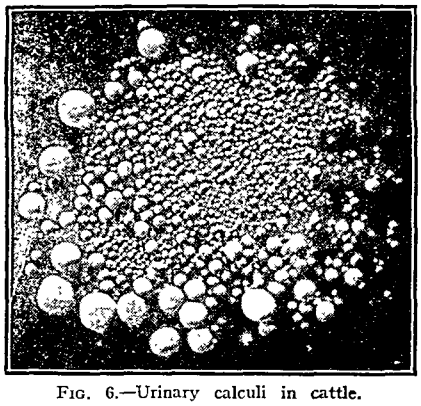

FIG. 6.—Urinary calculi in cattle.

same composition. Stones occurring in the kidney in cattle do not possess these physical characters: they are usually single, larger, of irregular shape, and are devoid of metallic sheen. But whether occurring in the kidney or in other parts of the urinary tract their chemical composition is, with rare exceptions, the same. Analyses have been made of twenty-four cattle stones in my laboratory (Ranganathan, 1931). Their composition has been found to be fairly uniform: calcium carbonate with a little magnesium, the latter presumably also existing as carbonate. In only one of the twenty-four stones was this composition departed from. In this case (a calf) the stone had a relatively high moisture content, a high nitrogen, phosphate, and magnesium content, and a low calcium content; carbonates were not present.

We have been fortunate in being able to reproduce not only the chemical but the physical (excepting the metallic sheen) characters of cattle stones under experimental conditions in albino rats (Figs. 7, 8). Briefly, this is how it was done. The rats were fed on a diet deficient in vitamin A and containing an excess of lime relative to the amount of phosphate in the diet (McCarrison, 1931). By keeping them on this diet for seventy to eighty days, and then supplying the missing vitamin A (in the form of radiostoleum) it was found that of those that survived the process a high percentage had stones of composition and physical characters closely resembling those of cattle stones. Apparently what happens is this. During the first, or vitamin-starvation, period an enormous mass (Fig. 7) of calcium carbonate debris is deposited in the urinary tract. On supplying vitamin A, but allowing the calcium-phosphate imbalance to remain, the whole (if it be small) or part (if it be large) of the calcium carbonate deposited during the first period is redissolved and dispersed. But in some cases parts remain as isolated collections or grains, and during the second period of the experiment, when vitamin A is provided, these act as foreign bodies, and a layer or layers of calcium carbonate is deposited around them. This is at present a working hypothesis; but we hope by hitting off just the right diet to keep the rats alive long enough, and by alternating the periods of vitamin-want and of vitamin-supply with sufficient nicety, while retaining the calcium-phosphate

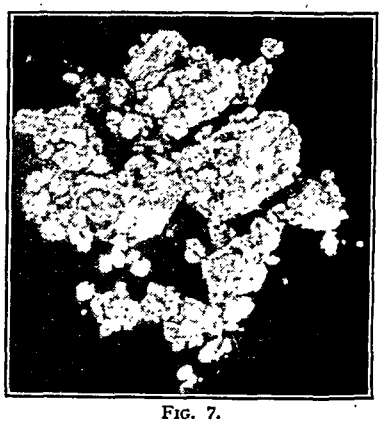

FIG. 7.

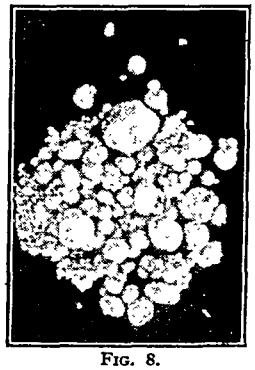

FIG. 8.

FIGS. 7 AND 8.—*Above*: Calcium carbonate concretions weighing 1,530 mg. removed from the kidneys of rat. *Below*: Calcium carbonate stones weighing 715 grams removed from the bladder of rat fed on a diet deficient in vitamin A and phosphate and containing an excess of lime. Compare the latter with the stones removed from the urinary tract of a bullock (Fig. 6).

imbalance, to reproduce these cattle stones with still greater exactitude.

In chemical composition the stones experimentally produced in rats were identical with the calcium carbonate stones found in Indian cattle (McCarrison, 1931).

Through the kindness of Mr. Hilson, Director of Agriculture, Madras, I have been able to secure reliable information regarding the food of the cattle in parts of the Madras Presidency where cattle stone is prevalent. They are fed on maize, millet, or rice straw, the husks of ground-nuts, and the empty pods of legumes. All these fodders are poor in phosphates and disproportionately rich in lime: ground-nut husks, for instance, contain as much as 3.78 per cent. of CaO and only 0.36 per cent. of P_2O_5. After the rains, the cattle obtain much more green fodder, and with it a much-needed supply of vitamin A. Periods of vitamin-want alternate with periods of vitamin-supply, the diet remaining all the while imbalanced with respect to calcium and phosphates. It is notable that the only exception to the rule that cattle stones are composed of calcium carbonate was in a calf, aged six months, which, after weaning, was fed on a diet in which calcium-phosphate imbalance was not marked. Strong support is thus lent to the hypothesis above mentioned as to the manner of calcium carbonate stone formation. Our investigations have shown, further, that in the formation

of these stones the calcium-phosphate imbalance is even more important than the vitamin A deficiency (Ranganathan, 1931). We find that the incidence of such stones can be very greatly reduced in rats by adding to the vitamin-A-poor and lime-rich diet an amount of sodium phosphate sufficient to form, with the excess of lime, insoluble calcium phosphate in the bowel. The further addition of vitamin A completely prevents the disease. I may therefore claim with some reason that the problem of "cattle stone" in India has been solved so far as the laboratory can solve it.

FUNCTION OF VITAMIN A IN THE PREVENTION OF STONE

In my last lecture I referred at some length to the effects of vitamin A deficient diets on epithelial structures throughout the body. No tissue suffers more severely from want of this vitamin than that of the urinary tract. It seems to me very probable that desquamated, keratinized epithelium from this tract may form the nidus round which calculus deposition occurs. It is true that in rats infection, as a rule, rapidly supervenes; and this, no doubt, may be in part responsible for the chemical composition of one variety of rat stone—the ammonium-magnesium-phosphate variety. But although naked-eye evidence of infection is the rule, exceptions occur in which this variety of stone is found without any obvious cystitis. Further, cystitis is no less common in rats suffering from calcium carbonate stones, and in these ammonium-magnesium-phosphate is conspicuous by its absence.

In my experiments I have found that the volume of urine excreted depends to a great extent on the presence or absence of vitamin A bearing ingredients in the diet; when absent or small in amount the volume of urine is low; when present in sufficient quantity it is normal or high. Sodium phosphate has also a very marked effect in this regard, greatly increasing the urinary excretion. It is significant that associated with the addition of vitamin A bearing substances (whole milk, cod-liver oil, or radiostoleum) to stone-producing diets, and of these substances and sodium phosphates to such diets containing an excess of lime, the urinary excretion from being scanty becomes copious, and at the same time stone is prevented.

There is, of course, another direction in which vitamin A acts in the prevention, and its deficiency in the causation, of stone. I refer to its power to prevent infection of the urinary tract, and to the influence of its deficiency in favouring such infection. This brings me to the last of the influences which may determine the occurrence and distribution of stone in India—infection.

INFECTIOUS INFLUENCES

The work of Rosenow and his colleagues of the Mayo Foundation is no doubt familiar: his experimental production of gall-stones in animals by infection with streptococci from cases of cholecystitis in man; and, more recently, his production of urinary calculi by the devitalization and infection of teeth in dogs with streptococci from cases of nephrolithiasis. Rosenow's procedure is, first, to produce "septic foci," using, for the disease he wants to produce, streptococci obtained from a case of the particular disease in man. He finds the coccus to be specific: that from cholecystitis will produce gall-stones; that from nephrolithiasis, urinary calculus. This sequence of events is probably the same in essentials as that occurring in rats: in these, foci of devitalization are produced in the urinary tract by the defective diet, and, in some forms of stone at least, chance infection may do the rest. But the point of special interest to India in Rosenow's work is that a specific kind of infection may, as he and Meisser suggest, be associated with stone, and thus account for the prevalence of the disease in certain localities. Personally, I am quite prepared to believe that this may, to a limited extent, be so; for although I have shown that the distribution of stone in India may, in some part, be accounted for by the kind of cereal used by people whose diets contain an insufficiency of vitamin A bearing ingredients, this is not the whole story, nor does it explain the occurrence of stone in all localities in India or in all individuals. Bilharzia, though a frequent cause of stone in Egypt, does not appear to be so in India; and in infection by bilharzia malnutrition is a potent favouring influence.

MECHANISM OF STONE PRODUCTION

This lecture has dealt with the causation of stone, not with the mechanism of calculus deposition. My researches have been mainly of the practical kind: my business being to tell the people of India how they can themselves avoid stone and prevent it in their cattle. It matters little to them, though it is of great interest to the medical scientist, whether the deposition of stone can be most satisfactorily accounted for by faulty metabolism due to dietetic causes, by infection, or by physico-chemical disturbances in the urinary tract. I have little doubt that both faulty food and infection may induce the physico-chemical disturbances responsible for stone deposition; but I know that a properly constituted diet will go a long way to prevent both infection and physico-chemical disturbances. It seems to me that all three agents—dietetic, infectious, and physico-chemical—play their part in the genesis of stone, and in designing its architecture; on occasion, and in certain individuals or in certain places, the star part may be taken by one or by the other. In India the star part is taken by diet.

The President and Council of the College have signally honoured me by their invitation to tell something of my research activities in India, and I have been deeply conscious of the responsibility this honour has imposed upon me. I have purposely chosen to refer only to those of my activities which I have thought might be of special interest to surgeons. Even with this limitation much has had to be omitted or passed by with but a few words. But if what I have said may serve to indicate directions in which the newer knowledge of nutrition touches upon the Art of Surgery—to indicate lines of investigation which hold out the prospect of the solution of certain surgical problems—then I shall have fulfilled, in some small measure, the duty imposed upon me by the invitation to address this great College.

A CASE OF TABOPARESIS TREATED BY HYPERPYREXIA INDUCED BY HOT BATHS

BY

C. R. GIBSON, M.B., CH.B.GLAS.

AND

R. G. GORDON, M.D.ED., D.SC., F.R.C.P.ED.

The treatment of general paralysis by hyperpyrexia has now become recognized as the most beneficial form of therapy for this disease which is known to us. Of the methods of inducing hyperpyrexia, the introduction of malaria parasites into the patient's blood has so far been found the most reliable and the most effective. This is no new observation, for Sir J. Purves-Stewart quotes a dissertation by Foster, written so long ago as 1848, on the beneficial effects of malaria on insanity.[1] The first systematic use of this treatment in general

paralysis was introduced by Wagner-Jauregg in Vienna in the year 1917.[2] Since then the method has been used with considerable success all over the world. In spite of this success the effects of malaria are less reliable than might be desired. Some patients do not contract the malaria at all, in spite of transmission of plasmodia to their blood, while in other cases the malarial infection fails to persist sufficiently to give the twelve attacks of fever which are regarded as the desirable course of treatment. On the other hand, troublesome relapses of the malaria are found to occur, and a certain number of fatal results from cardiac failure have been recorded. Other chemical (for example, sodium nucleinate) or toxic (for example, tuberculin) methods of producing hyperpyrexia have not proved any more reliable, and have hardly stood the test of time.

General Principles

While on a visit to San Francisco one of us had the good fortune to see the work of Drs. H. G. Mehrtens and P. S. Pouppirt on the treatment of various nervous affections by hot baths. This work has since been published,[3] but hardly does justice to what seemed remarkably striking results in the cases of general paralysis treated. A certain amount of doubt still seems to persist as to whether the results of malarial treatment are due to some specific effect of the plasmodium or its toxins on the progress of general paralysis, or simply to the hyperpyrexia induced. If it can be shown that treatment by hot baths is successful, then this would seem to afford definite proof that the hyperpyrexia is the beneficial agency. Further, there can be no doubt that this purely physical measure, if successful, has undoubted advantages over any other pyretic form of treatment. It does not involve the introduction of foreign toxins; the pyrexia can be accurately and exactly controlled, both as to extent and as to duration; and, provided that certain technical details are observed, the treatment is simple, easily applied, and safe.

The chief danger of this treatment is not so much hyperpyrexia as dehydration; for, as will be seen from the details of this case (confirmed by experiments on normal subjects under the same conditions), there is a very considerable loss of weight during the bath, due to secretion of sweat, which is quickly made up after the bath. This was born out by certain observations of Mehrtens. He found that this hyperpyrexial treatment relieved the gastric crises of tabes, though it did nothing to cure the tabes—a fact which we have confirmed in one case treated by this method. When the vomiting from the crises has been prolonged and severe, the patient is already severely dehydrated, and unless he is given plenty of fluid (preferably by rectum) before he is put into the bath he is apt to undergo the most alarming collapse. In all cases treated by this method, therefore, it is wise to provide means whereby fluid can be at once introduced into the system either by the rectum or subcutaneously. Care should be taken at the commencement of the treatment to determine the reaction of the individual patient to the hot bath, as it sometimes happens that his temperature may continue to rise one to one and a half degrees after he has left the bath; and if his temperature is already 103° F., as frequently happens, this may be undesirable.

We made use of a large reclining bath as described below, and the patient's temperature was recorded by a special self-recording electric thermometer prepared for us by the Cambridge Scientific Instrument Company. This instrument is of great delicacy and accuracy, and enabled us to know exactly what was happening in an initial experiment, and to give a graphic record of the pyrexia induced. We do not consider that such an instrument is essential for carrying out the treatment, so long as care is taken to establish the patient's reactions, since it is expensive and has the disadvantage that short-circuiting is very apt to occur in the lead between the rectal thermometer and the recording apparatus.

Case History

History of Present Illness.—Male, aged 35. In September, 1927, there was "apparent blood poisoning, believed to be due to eating pork. After attending various doctors, who said that he was suffering from digestive trouble and nervous dyspepsia, he showed no sign of improvement. Gradually fits of shaking commenced, which he could not control, and he had a feeling of numbness in his left leg." In 1928 the patient became irritable and depressed, and felt "as if his nerves were in great torment." He became impulsive and seemed to be losing his self-control. Then his memory began to fail. He forgot almost everything he was told and could not remember where he had put things. His work "seemed to be sapping every bit of his mind and strength." Sometimes he would be holding a cup or a glass and would seem to forget that he was doing so until he dropped it, and then the smashing of the glass would pull him together. This happened frequently. Since 1928 he has occasionally had "slight rheumatic pains and numbness in his knees and legs"; but he will not admit to any shooting or stabbing pains. About this time co-ordination became noticeably affected. He began to have difficulty in walking steadily. The numbness of the left leg increased, and his wife noticed that "he was throwing his legs out in a peculiar way when walking." On several occasions "his legs seemed to give out and throw him down on the ground." These tumbling-down episodes became more frequent, being especially marked in the dark or when he tried to turn quickly. In June, 1929, he had an attack of influenza. After this his general shakiness was greatly increased. His speech now showed a marked defect, and was hesitating. He would begin talking at his ordinary speed, then suddenly stop as if he could not get the use of his tongue, and then start off again very rapidly. When reading aloud to his wife he would mix up his sentences and run his words into one another so badly that she could not understand what he said. He began to be morose and unsociable, and shunned the company of other people.

In November, 1929, the patient removed to a house with a back entrance, as he had found that the neighbours in his old district were remarking on his speech and gait. His condition gradually became worse. He had to give up playing cards, one of his favourite recreations, as he could not remember which cards had been played. He became more and more irritable, and this mood alternated with fits of profound depression. He found increasing difficulty with his work in the designing department of a tweed factory; and when he came home at night he would spend the whole evening sitting by the fire without speaking to anyone. He became suspicious of his wife and easily upset by his only child (a girl aged 4 years). Formerly, he was passionately attached to this child, but now he began to be annoyed with everything she said or did. On one occasion he knocked her down a flight of three steps. One day towards the end of December, 1929, the patient's wife was calling on a neighbour and left the child in her husband's care. He became annoyed with something, left the child alone in a room with a fire, and went away, after locking all the doors in the house. When his wife returned she found the child screaming with fear, as she had never been left alone before. Two hours later the patient returned, having suddenly realized that the child was in danger from the fire. When he got into the house he collapsed completely, and for two days was continually shaking and weeping. In January and February, 1930, there was a continued deterioration in the patient's condition. When he spent money he could not remember what he had spent it on. He was becoming markedly emotional. If walking at night he had to be supported by his wife, and fell down frequently. He complained continually about his food, and his wife found that "he could digest

of dy invalid's diet." He was sleeping very badly. Incoordination was affecting him generally, and in kissing his child he would kiss her chest or her shoulder in an attempt to reach her face. Much against his inclination, the patient's wife persuaded him to see another doctor, and he was brought to see us on March 10th, 1930.

History of Past Illnesses.—Apart from the common maladies of childhood, and from several attacks of influenza, the patient did not admit to any previous illness. He would make no admission to syphilitic infection. He said that he was gassed in France in 1916, and at that time had a skin rash, which was treated by inunction with a blue ointment. Pressed further for an admission of the date of a primary syphilitic infection, he still strongly denied it. But when we offered him a loophole he accepted it readily, and said, "Of course I might easily have got it through using other men's towels."

Examination.—On March 10th, 1930, the main feature was a marked general coarse tremor of arms, hands, head, etc. He seemed to be alert, but in answer to questions betrayed marked lack of confidence in himself. He tended to be voluble, and it was difficult to keep his attention fixed on any one subject. His memory for dates and events, even of recent occurrence, was definitely poor. He had a greatly exaggerated opinion of his own importance and of the value he was to his employers; but he had none of the exaltation and delusions of the fully developed general paralytic. Speech was grossly hesitant, and he had a marked stammer. The slurring and clipping of syllables and fusing of words made it difficult to follow much of his conversation. Writing was jerky and of poor quality. The letters were pointed, unevenly spaced, and irregularly formed. There was a coarse tremor of the hands and arms; but, by concentrating his attention on this, the patient was able to control it to a great extent. It was most marked on movement. Tremor of the lips was pronounced, particularly when he was speaking, and there was constant tremor of the tongue. His gait was very unsteady. The feet were thrown out and brought down hard, and he walked on a broad base. Romberg's sign was present, and when turning sharply the patient had to be firmly supported to prevent a fall. The arm movements were unsteady, and the finger-nose test was poorly performed. Sense of position was also impaired. With the legs crossed the patient could not tell which leg, or which part of the leg, was touched, though he could feel the actual touch perfectly well. There did not appear to be any actual loss of power either in arms or in legs. There were no areas of hyperaesthesia. Sensibility to touch, pain, and temperature was unimpaired. Sensibility to vibration was below normal limits, though not entirely absent. The patient has had a slight strabismus for many years. There was neither diplopia nor nystagmus. The pupils were of medium size. The left was slightly larger than the right, and was not quite regular in outline. Reaction to accommodation and light was normal, and there were no pathological changes in the optic fundi. The knee-jerks and ankle-jerks were absent, and other tendon reflexes were normal. Skin reflexes were unchanged, and the plantar responses were flexor.

A blood Wassermann reaction taken on March 25th, 1930, was strongly positive. On April 6th a lumbar puncture was performed. The cerebro-spinal fluid was under considerably increased pressure, but it was quite clear. The following report was received:

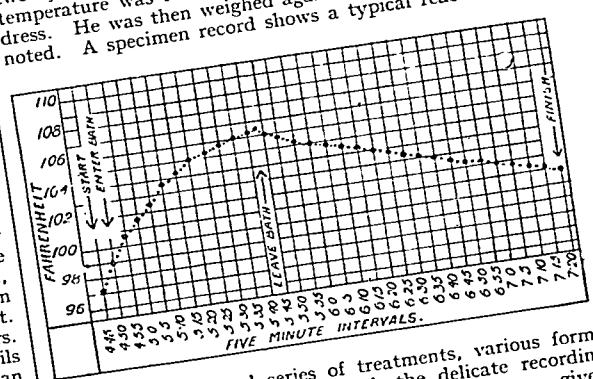
Foam test	Positive.
Globulin test	Positive.
Protein	0.10 per cent.
Cells	15 per c.mm.
Colloidal gold test... ...	0000114433.
Complement-fixation test... ...	Strongly positive.

It was then decided to adopt the experimental hot bath treatment in this case as the symptoms of general paralysis were not yet in an advanced stage. On April 25th, 1930, an injection of sodium nucleinate was given, and a leucocyte response was shown as follows: before injection, 6,600 per c.mm.; after injection, 9,100 per c.mm. This is a wise precaution before beginning hyperpyrexial treatment, since it demonstrates the patient's capacity for reaction.

TREATMENT

On April 29th, 1930, the following procedure was adopted. The patient was weighed (stripped), and after five minutes' rest on a couch the mouth temperature, pulse rate, and respiration rate were recorded. A sensitive recording galvanometer of the moving-coil type (thread recorder; Cambridge Scientific Instrument Company) was used to make a continuous graphic record of the rectal temperature. This apparatus was placed in the dressing-room leading off the patient's bathroom. We could thus watch for any sudden rise or fall in the patient's body temperature, and at the same time observe his general condition as he lay in the bath.

The metal thermometer, containing a delicate thermo-pile, was inserted into the patient's rectum while he was resting on the couch. As soon as the temperature was recording steadily he entered the bath. This was an ordinary reclining bath, and it was filled to the brim with water at a temperature varying in different experiments from 106° to 110°. A waterproof canvas cover was stretched across the bath and tightly bound down, there being a slot for the patient's neck, so that only his head was out of the water. Heat loss from evaporation was thus cut down to a minimum; and an attendant, watching a thermometer in the bath, kept the temperature even by the addition of a little hot water as required. Five minutes after the patient had entered the bath the mouth temperature, pulse rate, and respiration rate were recorded. These readings were repeated five minutes before the patient left the water. The duration of each treatment varied from forty to fifty-three minutes, the majority being about fifty-two or fifty-three minutes. The patient was then wrapped in blankets and made to rest on a couch for one and a half to two hours. The mouth temperature, pulse rate, and respiration rate were recorded twenty minutes after he left the bath; and the rectal temperature was recorded until the patient was ready to dress. He was then weighed again and the loss of weight noted. A specimen record shows a typical reaction.



During the several series of treatments, various forms of trouble were experienced with the delicate recording galvanometer, and a number of the baths were given without the use of this apparatus. On these occasions the mouth temperature, pulse rate, and respiration rate were recorded every ten minutes. In the earlier experiments we started with a high temperature (110° to 108°) and gradually lowered it when the patient showed signs of distress. But later we found that it was more satisfactory to start with a temperature of 106° to 107°, and to retain that level throughout the experiment. By this method we were able to reach and maintain a body temperature equivalent to that of the bath, thus producing a more sustained hyperpyrexia. Pulse rate usually reached a level of 120 to 140, respirations 50 to 65, and body temperature 105° to 107° (frequently 106°).

The patient invariably manifested some degree of distress during the last fifteen to twenty minutes of each session. Breathing became very rapid and shallow, and occasionally there was marked cyanosis. He sometimes complained of singing noises in his ears, of fullness in his head, and frequently of headache. On three occasions he became light-headed, but only twice was it considered necessary to finish the treatment before the expiry of fifty minutes. We found that fifty-three minutes was as

long a period as the patient could reasonably be asked to remain in the water. On almost every occasion distress was marked not later than forty-five minutes after the commencement. The average loss of weight during each bath amounted to 4½ to 5½ lb., the minimum being 3 lb. and the maximum 6 lb. 10 oz. By the next morning this loss had sometimes been more than made up. During the nine months of treatment the patient showed a net gain of 47 oz. (9 st. 11 lb. 13 oz. to 10 st. 12 oz.), and at one time he actually reached 10 st. 7 lb. 1 oz. The treatment did not hinder him from going to his work. He left work at 4 p.m. and started his bath at 4.45 p.m. Then he left for home at 7.30 p.m. (by which time he had cooled down to 100° to 101°), had his supper, and went to bed; by next morning he was fit to resume work.

The results of this experimental treatment have been most striking. Until July there was no definite change in the patient's condition, though there did not seem to be any progression of the disease. The course of eight baths in July, however, produced a very marked improvement. This was noticed particularly by the patient's wife, who said that he was no longer depressed, and only occasionally irritable. His speech was clearer, and his gait was slightly more steady. He was eating much better, and his insomnia had gone. The blood Wassermann reaction at the end of July remained strongly positive. Baths were started again in October, and twelve were given by the middle of November. Steady progress, both mental and physical, was shown. The patient's employers remarked on the improvement in his work, and he felt that he was much less easily tired. We noticed a distinct betterment in co-ordinated movements, and he could get into and out of his bath unaided. Up till that time he had to be assisted on both sides, especially when getting out of the bath.

On November 21st a complete examination of the cerebro-spinal fluid (which was still under fairly high pressure, but not so great as in April) was again made, with the following results:

Clear, colourless, no clot	
Foam test	Positive.
Globulin test	Positive.
Protein	0.09 per cent.
Sugar	0.07 per cent.
Cells	12 per c.mm.
Colloidal gold test... ...	0000421100.
Complement-fixation test... ...	Strongly positive.

Towards the end of January, 1931, we decided to give the patient another series of baths. This series was more prolonged than any of the previous ones, and sixteen baths were given by February 23rd—a total of forty-one. The result of this final series was exceedingly satisfactory. The patient is now a different man, both mentally and physically. In a letter which we recently received from his wife (an intelligent woman) she says:

"At the present time he has double the energy. He rarely gets depressed, never irritable, and he is mentally much sharper. Previously he was irritable beyond all words, and if things did not go just as he wanted he was beyond endurance. He walks faster and stronger, his speech is much clearer, and his writing is greatly improved. He can now digest almost anything, and he sleeps generally from 10 p.m. till 6 or 7 a.m. without wakening."

In conversation with us, she said that all their friends were remarking on the recovery of her husband's memory. He enjoyed playing cards again, and could do so in an intelligent way. He was a different man to live with, and was like the husband of three or four years ago. In walking in the dark she gave him no assistance, but he never fell.

Our examination at the end of February showed that he was alert and much more confident in himself. He still tended to be rather voluble, though much less so than a year ago; and he could now concentrate on the point under discussion. There was a very marked improvement in his memory. Speech was definitely better. It was sometimes slightly hesitant, but the slurring had gone. Writing was more even. The tremor of hands, arms, and lips was completely absent. There was still some tremor of the tongue, though it had greatly decreased. Gait was much steadier. He continued to walk on a broad base, though he did not throw his feet out so far. Romberg's sign was indefinite. When turning sharply there was some unsteadiness, but he could turn quickly without support and did not fall. Condition of arm movements was now good, and his sense of position was more accurate. There were no definite changes in the reflexes.

On April 6th, 1931, lumbar puncture was again performed. The cerebro-spinal fluid was still under pressure. A complete examination showed:

Foam test	Positive.
Globulin test	Positive.
Protein	0.06 per cent.
Sugar	0.08 per cent.
Cells	50 per c.mm.
Gold curve...	4444332000.
Complement-fixation test... ...	Strongly positive.

We have asked the patient's wife to send us a monthly report of her husband's condition. Meanwhile all treatment has been suspended.

COMMENTARY

It is to be noted that only the last gold curve is a true paretic curve. All other symptoms are suggestive of taboparesis. It will be admitted that the symptoms of this patient have improved very materially. His reflexes and Wassermann reaction are so far unaltered. The cerebro-spinal fluid shows signs of approaching a more typical paretic type, though the protein is definitely less and there is a slight diminution in the intensity of the Wassermann reaction. It should be clearly understood that we do not wish to draw any conclusions from this one case, but he has had no antisyphilitic or other sort of treatment than the hot baths. We hope that others who have more clinical material with which to work than ourselves may be induced to try this treatment and prove or disprove its utility. If it should prove successful, we believe it has much to commend it when compared with other methods of inducing hyperpyrexia.

We are indebted to the Bath Spa Committee and to Mr. John Hatton for the facilities allowed us in the bathing establishment, and to the attendants for the assistance given us in carrying out this experiment.

INDICATIONS FOR THE INDUCTION OF PREMATURE LABOUR*

BY

H. J. DREW SMYTHE, M.B., M.S., F.R.C.S.

HONORARY ASSISTANT OBSTETRICIAN AND GYNAECOLOGIST, BRISTOL GENERAL HOSPITAL

Under this title I want to include the indications for the induction of therapeutic abortion as well as the induction of premature labour; for in a large number of cases we may be faced with the problem of whether to evacuate the uterus in the early stages of pregnancy or to allow it to proceed, and, later, to induce premature labour.

NEPHRITIS

The commonest case brought to us for this reason is the chronic nephritic. In these cases one has to consider three things: first, the number of pregnancies; secondly, the term of pregnancy at which signs or symptoms of

* Read before the Bath and Bristol Branch on March 25th, 1931.

the nephritis were first observed; thirdly, the severity of the nephritis. The third, of course, is the most important, and for this the help of the physician and the laboratory is necessary; in fact, the last word in all these cases, whether or not to empty the uterus, should rest with the physician. Clinically, I consider the most important points to observe in these cases are: the quantity of urine passed in the twenty-four hours, the amount of albumin, the blood pressure, and the presence or otherwise of symptoms of impending uraemia, such as persistent vomiting or severe headache. In pregnancy two types of cases are met with. The first is that in which the patient is known to be a nephritic, and who, with or without treatment, shows signs of severe kidney dysfunction early in pregnancy. In this type of case I would advocate early evacuation of the uterus in order to prevent further damage to the kidney, because I do not think it is fair to the mother, unless it is her wish, that pregnancy should be allowed to proceed, with the consequent risk to her life and health, and with the probability of a stillborn premature child at the end. The second is that in which there has been a previous minor lesion of the kidney, which is able to deal adequately with excretion under normal conditions, but which with the added stress of pregnancy eventually breaks down. This type of case usually shows signs of failure much later in pregnancy than the first type, and also, if recognized earlier in pregnancy, responds to treatment. Induction of premature labour rather than therapeutic abortion is indicated. In either of these two types, if it is a first pregnancy, or even a later pregnancy, which is much desired by the parents, the patient may be placed on dietetic and medicinal treatment, and termination of pregnancy postponed until near term, unless danger signals arise. But in all cases of chronic nephritis I consider that induction is indicated between the thirty-sixth and thirty-eighth weeks in order to save the kidney further damage and, in many cases, to save the life of the child. Many of these children die *in utero* towards term.

The true albuminuria of pregnancy manifests itself only during the last month or so of gestation, and is usually amenable to dietetic and medicinal treatment. Induction, however, is indicated when treatment fails to keep the amount of albumin very low or absent, or when pre-eclamptic signs appear, such as persistent frontal headache, vomiting, visual changes, or gradual diminution of the daily output of urine, while the patient is under treatment. If the patient has not been treated, then the effect of treatment on these symptoms should be observed first. A case of pregnancy albuminuria which has reached the thirty-eighth week, and which, in spite of treatment, still shows albuminuria, should be induced, especially in the presence of marked oedema. Induction is performed in all my cases by drawing off a measured quantity of liquor amnii, without an anaesthetic if necessary. From 1/2 to 1 pint is usually removed, depending on the amount of liquor present. The relief of tension by drawing off the liquor amnii seems to have a definite beneficial effect in these cases, and labour usually begins in from twelve to twenty-four hours; occasionally it may be delayed for three days.

PERNICIOUS VOMITING

A large majority of these cases are cases of hysterical vomiting, or of vomiting induced in order to find an excuse for the termination of an unwanted pregnancy. Many of them develop an acidosis from carbohydrate starvation, and may go on from this to definite toxaemic vomiting. The presence of acetone and diacetic acid in the urine is not an indication for inducing abortion; it merely denotes the existence of an acidosis, which will usually clear up under hospital or nursing home treatment. The indications for clearing out the uterus in these cases are progressive loss of weight, bilious vomiting unconnected with the taking of food, scanty and albuminous urine (especially if blood is present), rises of temperature, rapid pulse, and the slightest sign of jaundice. Any one or more of these signs and symptoms may be present, making evacuation of the uterus imperative if the patient's life is to be saved. No pregnancy should be interrupted merely on the patient's statement of intractable vomiting, but only after a reasonable period of observation and treatment. Neither is pernicious vomiting in a previous pregnancy an indication that a present pregnancy should be terminated.

PYELITIS OF PREGNANCY

This condition usually yields readily to treatment, but severe cases are sometimes seen in which the condition does not clear up under treatment, or frequent relapses occur and the patient's general condition becomes progressively worse. In such cases induction is indicated. I have not seen a fatal case of pyelitis of pregnancy, but last year I was shown the kidneys of three patients who had died from this condition. There was in each case not only a pyelitis, but multiple small abscesses in the kidney substance, which I presume is the end-result of a *B. coli* infection.

CARDIAC DISEASE

Patients with compensated heart disease pass through pregnancy and labour usually without ill effect; but labour should be shortened by forceps delivery, or, better still, by an induction about the thirty-eighth week, especially if there is the slightest suspicion of disproportion. It is always of advantage in moderately severe, and necessary in severe, cases of cardiac disease, for them to rest in bed under supervision during the last month of pregnancy. In all cardiac cases the advice of a cardiologist should first be sought as to the advisability of pregnancy at all, and as to whether an accomplished pregnancy should be terminated at an early stage or allowed to go on to maturity. When compensation fails during pregnancy, then labour, whether commencing naturally or induced, is fraught with danger for the mother. Rest in bed and suitable treatment may re-establish compensation, in which case an easy labour should be ensured by induction at a period when the child is likely to survive and yet is small enough to pass through the maternal passage easily—that is, from the thirty-sixth to the thirty-eighth week.

PHTHISIS

Active phthisis is an indication for early evacuation of the uterus. Should pregnancy, however, have gone beyond the fourth month there is nothing to be gained by interrupting its course. During pregnancy there is usually a definite improvement in the patient's general condition, and labour proceeds normally; but in the puerperium the disease becomes rapidly worse in a large number of cases, and I have seen two patients in whom the disease progressed so rapidly, and with such swinging temperatures, as to simulate septicaemia. In my opinion no woman suffering from active phthisis should be allowed to become pregnant, or, if already so, pregnancy should be terminated at the earliest moment. It is useless waiting to see "how she gets on."

EPILEPSY

Cases arise in which the number of fits greatly increases during pregnancy; in fact, they always tend to do so. In some cases the first manifestation of epilepsy may be the occurrence of fits during gestation. Interference with the pregnancy is not necessary unless the fits become

too frequent, or uncontrolled by drugs and endanger the patient's life. Too rapid child-bearing has a bad effect on epileptics, and I consider that the number of children should be limited, both for the sake of the mother and of posterity. I recall one case, especially, of a young woman who had frequent children and more frequent fits, and who was fast losing weight and health. She came to me for her fifth pregnancy five months pregnant and with fits so frequent that she always had to have some one with her. I terminated the pregnancy by doing a subtotal hysterectomy. Now she is healthy, well nourished, improved mentally, and her fits are few and far between.

INSANITY

With the " bad family history of insanity " we are not concerned in this paper ; but we may be asked to evacuate the uterus in these cases. Whether we do so depends on our individual outlook, as we have no legal status in this matter. Puerperal mania, or insanity of lactation, in the previous pregnancy is, in my opinion, a definite indication for the termination of pregnancy.

DISPROPORTION

This is the condition above all others in which induction of labour is indicated. By this means there has been a large saving of maternal and foetal lives, the number of operations for Caesarean section has been decreased enormously, and patients who have previously had prolonged labours, with probably difficult forceps deliveries, have by a judicious induction been given a normal labour without instruments. No definite measurements and no definite term of pregnancy can be laid down as to the exact time when induction should be performed. Each case must be frequently examined, especially from the thirty-fourth week onward, and induction performed directly it is difficult to press the head into the brim ; definite overlapping should not be waited for. Induction should not be advised unless the true conjugate is at least $3\frac{1}{2}$ inches, and unless pregnancy can be allowed to proceed to the thirty-second week. If these conditions are not present, then Caesarean section should be performed in order to deliver a child that is likely to survive.

OCCIPITO-POSTERIOR POSITIONS

Induction of labour is often most successful in this condition. If cases of posterior lie with a normal-sized child and small pelvis, or a large child and a normal pelvis, are allowed to go to term there is either a prolonged labour before the head rotates forward or the occiput is unable to rotate forwards at all owing to the size of the head approximating so closely to the size of the pelvic cavity. This difficulty can be avoided in almost every case by induction of labour at the thirty-eighth week. This allows for a smaller head, which has more room in the pelvic cavity to rotate forwards, and as a result no further intervention is necessary in the majority of cases. At the same time as the induction is performed an attempt may be made to rotate the head and anterior shoulder into an anterior position, which may be maintained by pads and binder. This is by no means always successful, but in every case an attempt is worth while.

BREECH CASES

In some cases of breech presentation where external version has been unsuccessful (and these are generally found to be cases in which the legs are extended) induction at the thirty-eighth week, depending on the size of the child, in indicated. In breech cases another method of induction, other than the one described below, must be carried out. The advantage of induction in these cases is to get a smaller child and so make it more easy for a natural delivery to take place. Unfortunately even after induction it may be necessary to bring down the legs in order that the child may be delivered, but the smaller child makes this manœuvre easier.

METHOD OF INDUCTION

The method of induction which I always employ is a modification of the old method of rupture of the membranes. For this purpose I have had made a double curved silver catheter, similar to a prostatic catheter, with a blunt-ended stylet, which can be protruded at the distal end of the instrument. The vagina and cervix are cleaned up thoroughly with ether soap, and then with surgical spirit. Thorough cleansing of the vagina and cervix is essential in order to prevent any chance of introducing sepsis with the passage of the catheter. A Sims's speculum is introduced, and the cervix may be seized with vulsellum forceps, but this is not necessary unless the cervix is very posterior. No dilatation of the cervix is required. The catheter, with the point of the stylet withdrawn, is passed up the cervical canal until it meets the child's head ; the proximal end is then raised and the point of the catheter is passed behind the head, between the uterine wall and the membranes. When the point of the catheter has passed above the child's head the stylet is pushed home and the proximal end depressed ; by so doing the distal end ruptures the membranes. The eyelets of the catheter are now in the amniotic cavity, and liquor amnii commences to flow through the catheter, and is collected in a measured vessel. From half to one pint is drawn off, depending on the amount of liquor amnii present, and when sufficient has been collected the catheter is withdrawn. After the withdrawal of the catheter there is practically no further escape of liquor, so that when labour commences a definite quantity of amniotic fluid is still present.

The advantages of the method are that the opening in the membranes is made well away from the cervix, so diminishing the chances of septic infection of the liquor, that the bag of membranes is retained, and that there is no foreign body left in the uterus to invite sepsis or damage the uterine wall. The method is extremely simple and safe, both for the mother and for the child. Labour usually commences within twenty-four hours, but may be delayed for three days, or in a few cases for seven days. In spite of this delay I have not had a single case in which the liquor became infected. I can confidently recommend this method of induction of premature labour for all cases in which the foetus presents by the vertex, and I hope shortly to publish the results of its use during the past two years.

GONOCOCCAL STOMATITIS

BY

A. D. FRAZER, M.B., Ch.B.

V.D. MEDICAL OFFICER, COUNTY BOROUGH OF DUDLEY

AND

J. MENTON, L.R.C.P. AND S.I.

BACTERIOLOGIST, COUNTY OF STAFFORD

This condition is rare ; only about forty cases have been recorded since Neisser discovered the gonococcus in 1879. Our findings have an additional interest in view of the recent discussion in the *British Medical Journal* (February 14th, p. 263) on gonococcal infection of the nose.

Mouth infection in the newly born, like ophthalmia neonatorum, occurs during transit of the maternal passages (Rosinski,[1] Leyden,[2] Kast[3]). In adults infection is usually direct, but Chevelle and Georgel[4] have reported a case of metastatic involvement of the buccal cavity. Rosinski[1] gives five to twelve days as the incubation period in infants. In adults, for obvious reasons, it is more difficult to determine, and seems to vary from one day (Petrasie[5]) to seven days (Bronson[6]). The parts most often affected are the soft palate, the pillars of the fauces, the anterior part of the tongue, and the gingival margin

in the anterior part of the mouth (Mead[7]). The mucosa is bluish or rosy red, and the lesion has been described by Mead,[7] Rosinski,[1] and Bronson[6] as a sharply localized whitish or yellowish-white patch surrounded by a reddish zone. The gums are usually inflamed, swollen, and retracted. The breath is offensive, and the mouth movements are extremely painful. Healing occurs without much scarring.

HISTORY OF CASE

In the case we have to record, an unmarried man, aged 23, exposed himself to infection on March 13th, 1931. On the 15th he suffered from nausea, and repeatedly put his fingers down his throat to make himself vomit. Next day he had a discharge from the urethra and from both eyes. On the 17th his gums were swollen, and the following day he noticed a purulent discharge from the mouth. Dysuria had developed by this time, but there was no frequency of micturition. He was admitted to hospital on the 19th. The purulent discharge from the urethra contained gonococci. The usual tests revealed that the infection was limited to the anterior urethra; and the epididymes, spermatic cords, seminal vesicles, and prostate were unaffected. The eyes showed a bilateral purulent ophthalmia; the corneae were unaffected. The buccal mucosa, anterior half of the tongue, the gums, and the tonsils were coated with a greyish adherent membrane. In places the membrane had sloughed off, leaving bright red areas with numerous bleeding points. These superficial ulcers were more numerous in the neighbourhood of the molar teeth than elsewhere. The gums were swollen and retracted. Pain in the mouth was a prominent symptom. He looked seriously ill. His temperature was 101° F.

Diagnosis

On March 21st plates of Thomson's medium were conveyed in a portable incubator from Stafford to Dudley, a distance of 22 miles. The lamp of the instrument was lit before leaving Stafford, so that the medium was warm on arrival at Dudley. This is an important precaution when dealing with a delicate micro-organism like the gonococcus. Swabs were taken from the patient's mouth and were sown on six plates, which were immediately put into the incubator and sent back to Stafford by road. These details are mentioned to show that distance is no impediment with proper equipment and precautions. After forty-eight hours' incubation, four of the plates showed an abundant growth of pneumococci and staphylococci; the remaining two revealed, in the midst of a similar growth, some colonies having the usual appearances of gonococci. These were subcultured until they became habituated to artificial conditions and were then submitted to the usual biochemical tests. They gave the reactions of gonococci, producing acid in glucose, but not in maltose or saccharose. These micro-organisms isolated from the patient's throat will be for convenience designated as "the Dudley strain." They were not agglutinated by the patient's serum which was drawn off within the first week of the disease; and, using them as an antigen, the complement-fixation test on the patient's serum was negative, as it was with the stock laboratory antigen. Considering all the circumstances, these results cannot be regarded as exceptional.

A rabbit was inoculated with a Stoke strain of gonococci obtained some time ago from Dr. McElligott's clinic. The micro-organisms were first killed by formalin. The agglutination reactions of this animal's serum at different periods after inoculation are interesting:

	5th Day	7th Day	10th Day	17th Day
Stoke strain	1 : 125	1 : 500	1 : 250	1 : 50
Dudley strain ...	1 : 125	1 : 250	1 : 250	1 : 50

Adsorption tests showed that the Stoke strain removed all the agglutinins for the Dudley strain, and the Dudley strain rendered the serum negative for the Stoke strain. Both strains were negative to normal horse serum, but were agglutinated in strong dilutions by Types I and II, and by polyvalent antimeningococcal serums; but as these reactions are usual and merely proclaim the close antigenic relationship between the gonococcus and meningococcus they will not be further discussed. The rabbit's serum was submitted to complement-fixation tests. Dr. Price's technique[8] was adopted. Using the Stoke and Dudley strains as antigens, the following results were obtained at the periods stated:

	5th Day	7th Day	10th Day	17th Day
Stoke strain	—	±	+ ±	+
Dudley strain ...	± —	+	+ ±	+

Several direct films made from swabs from the mouth showed Gram-negative intracellular diplococci having the morphological characters of the gonococcus. A differential blood count showed slight eosinophilia up to 4.5 per cent.

Treatment

Treatment was started with urethral irrigations of a 1 in 8,000 solution of potassium permanganate, and an alkaline diuretic was given by the mouth. The eyes were bathed every two hours with a 1 in 5,000 solution of oxycyanide of mercury, and drops of 20 per cent. argyrol were instilled. The mouth was washed out frequently with a 1 in 5,000 solution of potassium permanganate. A detoxicated gonococcal vaccine (starting with 2,500 million organisms) was given alternately with small doses of edwenil (1/2 c.cm.) at two- to three-day intervals. Treatment was started on March 19th, and progress was as follows: March 24th, temperature normal; March 28th, no urethral discharge, and both urines in two-glass test clear; March 30th, the discharge from the eyes, which had been very slight for the last four days, now entirely ceased; April 4th, grey membrane covering mouth completely gone and normal healthy colour reinstated; no swelling of gums and no pain. The patient passed very rigorous tests for cure, and was considered free from infection six weeks after his admission to hospital.

COMMENTARY

The gonococcus must have been carried to the buccal mucosa when the patient attempted to make himself vomit by putting his fingers down his throat. This was two days after exposure to infection and one day before he noticed the urethral discharge—ample time for the gonococcus to multiply in the urethra and produce a highly infective, but not obvious, mucoid secretion. The other possibility here is a metastatic spread. The urethral discharge appeared on March 16th, the gums were swollen on March 17th, and the stomatitis was fully developed on the 18th, so that the time factor alone almost excludes this route. Added to this, the fact that the urethritis remained anterior throughout the whole course of the attack, and the lack of involvement of the prostate and seminal vesicles, allow us to exclude metastatic infection. The case with which the gonococcus was isolated from the superficial exudate in the mouth, and the failure to find complement-fixing factors or agglutinins in the patient's serum after the stomatitis had ensued, further confirm these conclusions. The eosinophilia has no relation to the stomatitis. It is an occasional accompaniment of gonococcal infection (Buchanan,[9] DaCosta[10]).

The lesion in this case is different in some respects from any we have seen described in the literature. Instead of the sharply localized whitish patches surrounded with

a reddish zone which previous observers have noted, the whole of the mouth, tonsils, and anterior half of the tongue were covered with a grey membrane. Before treatment was commenced there were a few patches of superficial ulceration, chiefly around the molar teeth, where the membrane seemed to have been forcibly removed, possibly by the action of food or the tongue. While under treatment the membrane sloughed off in parts, showing red mucosa beneath without ulceration. The redness gradually faded until the normal colour was resumed. The rarity of this complication is striking, and is possibly due to the reaction of the saliva and the nature of the buccal mucosa. The presence of other micro-organisms, as in this instance, may allow the gonococcus to become established. Any unhealthy or septic condition of the mouth may act as a predisposing cause—gingivitis, pyorrhoea, dental ulcers, etc. Klepper[11] describes the case of an old woman who had simple ulcers of the mouth. She took care of a child with gonococcal urethritis, and herself developed a gonococcal stomatitis. In the case under discussion there were no such predisposing causes, and the patient was a healthy young adult. As a last resort, one must think of a specially virulent strain of gonococcus. That such strains occur seems quite definite clinically, although no bacteriological proof is yet forthcoming.

Concerning treatment, most writers advise the application of a solution of silver nitrate, 1/4 to 2 per cent. (Mead,[7] Vines,[12] Rosinski[1]). Petrasie[5] used an alum gargle and cured his case in a week. Janet[13] suggests a mouth-wash of potassium permanganate. As the gonococcus is easily killed by a weak solution of almost any disinfectant (its power lying in its inaccessibility), the choice of a mouth-wash seems unimportant. Potassium permanganate was used in this case, as it has the chief claim to an approach to specificity.

Although we had found by direct film numerous cells filled with Gram-negative diplococci which showed the morphological characters of gonococci, we were not prepared to make a diagnosis on these results alone, for it has been our experience that in the genito-urinary system and elsewhere Gram-negative intracellular diplococci may occasionally be found which are not gonococci. In the mouth numerous Gram-negative cocci frequently occur—for example, *M. catarrhalis*, meningococcus, parameningococcus, *M. pharyngis siccus*, the various types of *M. flavus*, and others. So that, if we had based the diagnosis on unsupported direct films, our findings would be open to serious criticism. We do not, however, wish to create the impression that the direct film is always worthless. A Medical Research Council Report[14] sums up the position thus:

"(*a*) That Gram-positive organisms when taken up and digested by leucocytes may lose their Gram-positive character.

"(*b*) That more than one observer has noted, in cases of chronic gonorrhoea in which the material is such that a satisfactory film is difficult to obtain, that organisms determined by culture to be gonococci retain the violet stain with unusual obstinacy, and appear thus to be Gram-positive.

"(*c*) That the stain as such does not distinguish between gonococci and other Gram-negative, but non-pathogenic, diplococci which may be present in both male and female genito-urinary tracts.

"The Committee are of opinion that these limitations do not seriously affect the diagnosis of the one order of cases in which, in their view, diagnosis by microscopical examination alone gives consistent results—namely, the active acute cases of the disease."

SUMMARY

This is a synopsis of the known facts on gonococcal stomatitis. An actual case is briefly described and an outline given of the measures adopted to place the diagnosis beyond reasonable doubt.

TORSION OF OVARIAN CYST WITH BRADYCARDIA

BY

R. FRANCIS MATTERS, M.D., CH.M., F.R.C.S.ED.

LECTURER IN HUMAN PHYSIOLOGY AND TUTOR IN OBSTETRICS, UNIVERSITY OF ADELAIDE

Many incidents have been recorded concerning twisted pedicles of ovarian cysts, particularly in children. A perusal of the literature, however, does not elicit any reference to slowing of pulse rate during the torsion, or at any other time. In 1893 Keen[1] recorded a case of ovarian cystoma weighing 111 lb., in a child of 15, but there appear to have been few symptoms and signs other than those due to pressure. Palmer Findley[2] records the case of a girl, also 15 years of age, who had a cyst of 32 lb. without untoward effects. Reuben[3] presents a report containing a reference to a girl, aged 14, who had an ovarian cyst with a twisted pedicle, without very unusual signs. The onset of menstruation at the age of 7 in a child with a large ovarian cyst is mentioned by Keatings.[4] Others, including Chu,[5] Nutt,[6] Pillai,[7] and Stevens[8] have placed on record their findings in cases of ovarian cysts. Nowhere, however, does slowing of the pulse rate appear to be mentioned.

THE ORIGIN OF BRADYCARDIA

Slowing of the heart has been noted in some cases of gastro-duodenal origin, and extrasystoles have been noted in connexion with digestive disorders. Cases of extrasystole in this group are usually found in young adults; they are due to afferent autonomic impulses stimulating the vagus centre. The result of this is that the vagus produces its inhibitory influence upon the cardiac rate, and the cardiac cycle may be so affected at times that the prolonged diastole is of such an interval that the intrinsic ventricular beat becomes manifest, with the production of an extrasystole. The condition is similar to the ventricular escape resulting from continuous vagal stimulation experimentally, in which the ventricle begins its own rhythm, as in cases of complete heart-block.

HISTORY OF A CASE

A girl, aged 20, came to me with a history of having had two attacks of pain on the right side. When I first saw her she was lying with her legs flexed, and was groaning with pain, which was most intense in the lower right abdomen. No actual vomiting had occurred, but she complained of nausea. The temperature was 100.4° F., the pulse rate was 52, and the respiration rate 32. The catamenia was of average type, being a twenty-six-day cycle, with a menstrual flow lasting four days.

The case was obviously an acute abdominal condition, but the slow pulse rate was most unsatisfactory as a guide. The patient looked drawn and ill. The abdominal wall was very rigid, especially in McBurney's area; therefore we first

thought of acute appendicitis. Although the patient was thin, there was no obvious alteration of the contour of the abdominal wall, but a curious thrill was obtained in the lower abdomen, so that torsion of an ovarian cyst was also considered.

Under anaesthesia, the patient was catheterized, but the cystic mass remained. Through a mid-line incision a large mulberry-like mass was encountered; it was connected with the right broad ligament by a pedicle that had rotated five times. The cyst was multilocular and anatomically a parovarian cyst. This purple mass, about the size of a coco-nut, was readily removed, but the ovary which was involved in the pedicle was saved. A very congested appendix was also removed, and the patient made a good recovery.

The pulse rate during the first twenty-four hours was about 60, and became faster and faster, so that in two days it reached 84, at which it has since remained.

COMMENTARY

The bradycardia is the feature of great interest in this case. Was it due to the appendix or the cyst, or might the two have combined to produce this unusual state? The suggestion offered is that the afferent stimuli from the twisted pedicle travelled by the autonomic fibres to the vagal centre, and also to its neighbour, the respiratory centre. The vagal response was a decrease in cardiac rate, or in this case the bundle of His might have been impaired, producing a two to one heart-block. The fact that the pulse rate gradually returned to normal indicates that the vagal inhibition was probably the cause, and the relatively large number of autonomic nerves in the area adds weight to this conception.

In conclusion, it may be pointed out that the above facts do not accord with the usual assumption that the peritoneal irritation necessarily provides all the indications of shock, including increased pulse rate, and that the increased pulse rate is a guide to the diagnosis.

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

TUBERCULOSIS OF THE MAMMARY GLAND

Tuberculosis of the mammary gland is a comparatively rare condition. Wakeley[1] states that only 212 cases have been recorded. He describes two forms (1) disseminated, (2) confluent, in which a single chronic abscess cavity is formed. The commonest cause of infection is via the blood stream secondary to pulmonary tuberculosis, but infection may occur as a result of direct contact following tuberculosis of rib or sternum. More rarely the source of infection is pleura or axillary lymphatic glands. The following case is of interest, as illustrating the presence of a single chronic tuberculous abscess cavity in the breast tissue, following lupus of face with tuberculous cervical and axillary glands of many years' standing.

A married woman, of coarse, swarthy type, born in 1893, was referred to me at the Tuberculosis Dispensary, Leigh, by her doctor in June, 1917. She was well nourished and had several scars (some scabbed over) on both sides of her neck and under her chin. There was slight discharge here and there, with some enlargement of the cervical and left axillary glands. Scraping was performed at the Manchester Royal Infirmary and she was discharged on July 26th, the lesions being apparently healed. In January, 1918, she had several small glands down the left side of her neck, with many scars and some scrofuloderma; she was doing her housework. After September, 1918, she ceased attendance at the dispensary until January, 1920, when painful swollen glands in the left axilla and lupus of the right cheek were noted. Her condition improved following treatment at the Manchester and Salford Skin Hospital. When she next visited the dispensary in May, 1923, there was extensive lupus of the right side of face and neck, together with a discharging sinus in the left axilla. She again attended the Skin Hospital regularly, and in September, 1926, she had extensive scars from ear to ear, with only a few active spots of lupus. She visited the Leigh Dispensary at intervals, and in January, 1931, she drew attention to her right breast, when a firm swelling was detected in the upper and outer quadrant adherent to the skin, but freely movable on the deeper structures. There were scars of old sinuses in both sides of neck and both axillae, also lupus of the right cheek. There was no evidence of pulmonary tuberculosis.

She was admitted to the Manchester Royal Infirmary, and the tumour, with overlying skin and surrounding tissue, was removed by Mr. A. H. Southam. The following particulars were kindly supplied to me by the surgical registrar (Dr. R. P. Osborne): Section of tumour at the time of the operation proved that it was an abscess. Subsequent pathological examination of the whole of this material resulted in the following report: "Section shows the structure of tuberculosis with caseation and abscess formation." The tumour was thus a tuberculous abscess.

With some intermissions, this patient was under frequent supervision at a tuberculosis dispensary for thirteen and a half years, first of all with tuberculous adenitis of neck and scrofuloderma, and subsequently with lupus of right cheek. The development of the tuberculosis of the mammary gland appears to have been a direct sequela of the foregoing conditions.

GEORGE JESSEL, M.D., D.P.H.,
Consultant Tuberculosis Officer,
Lancashire County Council.

Reports of Societies

PHARMACOLOGY

A meeting of the Pharmacological Section of the Royal Society of Medicine was held in the Pharmacological Laboratory, Cambridge, on May 30th, with the president of the Section, Dr. P. HAMILL, in the chair.

AVERTIN AND THE LIVER

Dr. F. B. PARSONS read a communication on "The action of avertin on the liver," in which he described some preliminary experiments designed to show the effect of avertin (tribromethyl alcohol) upon the liver. For some considerable time it had been known that organic halogen compounds were prone to cause liver damage. More recently Lucas had investigated the effects of certain bromine-containing anaesthetics—namely, bromoform, ethylene bromide, ethyl bromide, and methylene bromide—upon rabbit's liver, and he had concluded that these substances were capable of producing fatty degeneration and necrosis of this organ. Dr. Parsons stated that he had repeated these experiments with avertin. A series of rabbits were given this drug, and after varying periods they were killed and the livers were examined histologically. Technical difficulties in the histology of rabbit's liver made it impossible to draw any definite conclusion, but in all the sections there was a certain amount of fatty degeneration. He proposed to repeat the experiments upon dogs.

Sir FRANCIS SHIPWAY mentioned that he had successfully administered avertin for the performance of cholecystectomy in a case of congenital cystic liver.

Sir WILLIAM WILLCOX pointed out that there were good grounds, *a priori*, for expecting that avertin would produce liver damage. In his opinion, it ought to be used only by experienced anaesthetists, and, by them, with great caution. It was not a substance which should be let loose on the medical profession. It was, for instance, unsafe to use it with morphine, and idiosyncrasy among patients might easily be met with.

Dr. J. BLOMFIELD asked for evidence that avertin was a liver poison. Sir WILLIAM WILLCOX replied that his statement had been made on general grounds. Dr. PARSONS said that the difference between clinical and laboratory experience was probably to be explained by the variations in dosage.

CEREBRAL METABOLISM

Dr. ERIC HOLMES read a paper by himself and Mr. ASHFORD dealing with the metabolism of the central nervous system. He described work which showed that the brain was dependent for its supply of carbohydrate upon sugar carried to it by the blood stream; this carbohydrate was quickly converted to lactic acid, which was, in turn, oxidized. The store of lactic acid precursor in the brain was negligible in amount. The brain was clearly dependent for its normal functioning on its carbohydrate supply, and apparently the conversion of glucose to lactic acid was of importance, for after injections of glucose, but not lactate, animals recovered from hypoglycaemic convulsions. The carbohydrate metabolism of brain tissue differed in important respects from that of muscle, for no phosphate ester formation took place, nor was there resynthesis of carbohydrate from lactic acid. The demands of the brain for oxygen were very great. Analysis showed that nerve cells used oxygen at a far greater rate than nerve fibres, and the oxidative processes in the two tissues were profoundly different. The chemical differences between medullated and non-medullated nerve tissue were very marked.

The PRESIDENT said that the problem was one of great difficulty and complexity, but that work on these lines was a necessary preliminary to an understanding of the pharmacological problems connected with the central nervous system.

DIGITALIS IN TOXAEMIA

Dr. G. N. MYERS, in a paper on the curative action of digitalis in toxaemia, said that his experiments showed consistently that if a reliable tincture of digitalis were given to guinea-pigs, they survived subsequent injections of diphtheria toxin, even if the amount of toxin was approximately three times the minimum lethal dose. The control animals, which had the toxin without the previous digitalis, invariably died. The same effect was obtained when the toxin was injected first, provided that the injection of the digitalis was not too long delayed. It was also found that the glucosides from strophanthin (from *S. kombe*) exerted some life-saving effect, though not to the same extent as that given by digitalis; g-strophanthin had no action of this type. Animals which received ouabain died a little sooner than those which had received the toxin alone. The effect of toxin on the animals which had received digitalis was different from that on normal animals; the former responded by a decided leucocytosis, in the latter the leucocytosis was never a decided feature, and was generally absent. Experimental and clinical evidence showed that diphtheria toxin generally killed by causing circulatory failure associated with enormous dilatation of the splanchnic vessels, and a progressive fall in blood pressure, a condition which was not due to the depletion of the suprarenal glands. It appeared that digitalis was of benefit in these shock conditions because it was retained by the tissues of the vascular system. It seemed as though, when an animal was under digitalis, there was little or no place for absorption of toxin. Digitalis had to be administered for many days before perfect action was obtained, and this fact suggested that the drug occupied some portion of the cardio-vascular structure to which the toxin normally attached itself; at all events, if digitalis were given first and had time to act, the toxin was without effect, but if the toxin were injected first, subsequent digitalization, if delayed, might be too late to be effective. Histological examination of hearts from these animals, stained for fat by means of osmic acid, revealed that the great majority of animals which had received digitalis showed considerably less fat in the myocardium than was seen in the controls. References were also made to special preparations of digitalis and to the effect of digitalis on other forms of toxaemia.

The PRESIDENT said that they had listened to a description of a most important piece of work. The contrast between the actions of the two strophanthins was of interest. It appeared that digitalis was more effective than strophanthus, and *that*, in turn, more effective than digitoxin. He felt that experiments should be done in which digitalis was administered by the mouth.

Professor W. E. DIXON remarked that, whatever the mode of action of digitalis in this case, it seemed to be different from that which they were accustomed to teach their students. It seemed to prevent the toxin from acting by saturating some structure in the heart cells, and so preventing the toxin from reaching them. The explanation, he felt, might be found along physical lines.

Sir WILLIAM WILLCOX asked whether any proprietary preparations of digitalis had been employed. Dr. MYERS replied that the preparation known as "diginutin" had proved quite beneficial, though less effective than the ordinary tincture.

Sir HUMPHRY ROLLESTON recalled that Dr. Jones of Jersey had long ago pointed out the beneficial effect of digitalis in alcoholic delirium. He asked whether the electrocardiograms had shown no effect at all, or whether they indicated the same action as on a normal heart. He also suggested as a possible alternative explanation to that offered by Professor Dixon, that in this case digitalis acted in a manner similar to a bacterial antitoxin. Dr. MYERS recalled the beneficial effects of digitalization in pneumonia obtained by certain American workers.

OESTRIN AND PITUITRIN

Dr. J. HELLER, in presenting a paper by himself and Dr. P. HOLTZ, said that the work had been concerned with the effect of oestrin, the anterior pituitary hormone, and potassium and calcium ions, on the response of the isolated uterus to pituitrin. He recalled the familiar self-sensitizing effect of pituitrin on the isolated uterus, and pointed out that this effect had been eliminated in the present experiments. Bourne and Burn had found that oestrin had a sensitizing effect on the uterus, and they suggested that it might be a natural sensitizing agent. The speaker and Dr. Holtz had confirmed these experiments with oestrin, but oestrin preparations contained protein; with "progyon," a protein-free preparation, and "theelin," prepared from crystalline oestrin, they had failed to obtain the effects, even with enormous doses, and therefore did not agree with the conclusions of Bourne and Burn. They had found that preparations of anterior pituitary hormone had no direct effect, but sensitized the preparation to pituitrin. Changes of the potassium-calcium ratio of the suspension fluid sensitized the uterus to pituitrin if potassium was predominant in amount. A "Burn-Dale" solution containing 25 per cent. less potassium than normal had a marked sensitizing action. He pointed to the parallel which existed between these experiments and the altered potassium-calcium ratio in the blood and in the uterus

of pregnancy. This alteration, of course, leaves potassium predominant.

Professor DIXON recalled the experiments of Dixon and Marshall, which showed that there was an increase in the pituitary content of the cerebro-spinal fluid about the time of parturition. This had been thoroughly confirmed by clinical workers. He was chiefly interested in the present communication because it showed that oestrin had no effect on the uterus. This was in accordance with clinical experience. Oestrin would produce oestrus in a spayed animal, but that was its only known physiological action. It could be obtained from the most diverse sources, and might even be a metabolic product of relatively simple chemical structure.

ACTION OF HISTAMINE

Dr. J. C. HOYLE, in a paper on the action of histamine, pointed out that, although the action of histamine in simulating the condition of "shock" had been widely studied, no thorough investigation of its action on the pulmonary circulation had been made. In collaboration with Professor Dixon he had recently made an experimental investigation of this subject. It was found that the action of the drug varied greatly in different species, and deductions made on the basis of experiments carried out on one species were not valid for others. The initial effects in the dog after intravenous injection of histamine were due to a local action on the heart and pulmonary vessels, and occurred before the drug had acted upon the systemic circulation; they were due to cardiac acceleration and constriction of pulmonary arterioles, and did not occur if the injection was made into a systemic artery. These effects were transient, and were followed by a second phase, in which the amount of blood passing through the lungs was much diminished. The changes were described in detail, and were considered to be due to constriction of the hepatic veins, which were exceedingly sensitive to histamine in the dog. The action of histamine in the cat and rabbit was then dealt with; in the former, coronary dilatation played the dominant part; in the latter, pulmonary arteriolar constriction. The effects produced in the monkey (*Macacus*) had also been investigated, and were found to be intermediate between those in the dog and those in the cat. Coronary dilatation was probably an important factor. The monkey was abnormally sensitive to histamine compared with the dog, cat, or rabbit.

The PRESIDENT said that he had no doubt, from clinical experience, that histamine produced marked constriction of veins. Professor DIXON said that he could not believe that the distension of capillaries produced by histamine was more than a passive effect due to constriction of venules. This was the simplest view of the action of histamine, and it still remained to be disproved.

UTERINE PROLAPSE

A meeting of the Edinburgh Obstetrical Society was held on May 13th, with the president, Dr. H. S. DAVIDSON, in the chair.

A paper on uterine prolapse was read by Miss GERTRUDE HERZFELD and Miss MARGARET C. TOD dealing with an investigation into 227 cases of prolapse operated on between 1922 and 1929, and including a comparison of the pre-operative clinical features with the post-operative results. Of the 227 cases, 132 were traced for periods varying from one to seven years. The following table gives the general idea of the conditions present before operation. It will be noted that the complaint of "something coming down" was not universal, and that a woman with cystocele, rectocele, and cervix at the vaginal orifice may have little local discomfort, but may report on account of discharge or backache. Frequency of micturition was one of the most constant symptoms in all varieties of prolapse, and was present before operation in 70 per cent. of the 227 cases, while every patient with total prolapse had incontinence. Vaginal discharge was complained of in every case where a lacerated cervix was found, and 30 out of 34 such patients also suffered from backache. On the other hand, only 10 out of 39 women with complete prolapse had this symptom. Complications after operation were associated with sepsis, and consisted either of secondary haemorrhage which occasionally occurred after amputation of the cervix or, still more rarely, of sloughing of the wound.

TABLE I.—*Showing Analysis of Symptoms Complained of before Operation*

Condition found at Operation	Total Number	"Something Coming Down"	Frequency of Micturition	Precipitate Micturition and Incontinence on Straining	Vaginal Discharge	Backache	Constipation	Incontinence of Faeces	Pruritus
Cystocele only	22	16	18	10	12	1	2	0	0
Rectocele only... ...	18	2	1	0	14	16	12	5	0
Cystocele and rectocele	89	83	59	32	51	48	14	0	1
Cystocele with hypertrophy of cervix	10	9	8	2	8	4	1	0	0
Cystocele and rectocele with hypertrophy of cervix	17	17	10	6	14	13	4	0	0
Cystocele and rectocele with lacerated cervix	34	32	26	24	34	30	8	0	1
Complete prolapse ...	37	37	37	37	20	10	10	0	2
Totals	227	196	159	111	153	122	51	5	4

The operative technique evolved by Donald and Fothergill of Manchester was followed in practically all cases, and the authors considered that abdominal surgery was never required for the cure of prolapse. The results of operation are shown in Table II. Out of 132 patients

TABLE II.—*Showing Analysis of Results of Operation*

Condition found at Operation	Total Number	Cured; no Symptoms	Uterus, etc., in Good Position, but Urinary Symptoms Present	Prolapse Recurred	No Symptoms; Slight Cystocele found on Examination	Post-operative Pregnancies	
						Norm.	Inst.
Cystocele only ...	11	7	3	1	0	0	0
Rectocele only ...	6	4	2	0	0	1	2
Cystocele and rectocele	55	47	8	0	1	3	0
Cystocele with hypertrophy of cervix	7	5	2	0	0	1	1
Cystocele and rectocele with hypertrophy of cervix	13	12	1	0	0	1	0
Cystocele and rectocele with lacerated cervix	19	17	2	0	0	2	0
Complete prolapse ...	20	17	0	1	2	0	0
Totals	132	109	18	2	3	8	3

127, or 96 per cent., were completely cured, though 18 patients had slight frequency of micturition. In all these the urine was acid, and in the majority a slight *B. coli* infection was present. All symptoms disappeared on the administration of potassium citrate, but in two cases, treated early in the series, there was recurrence.

As a result of these investigations it was concluded that: (1) surgical treatment of uterine prolapse was a safe and satisfactory method of treatment; (2) abdominal surgery was never required in this condition; (3) the

operation resulted in a feeling of well-being often not experienced by the patients for many years previously; (4) pessary treatment, while palliative of symptoms, should be used only in cases where operation was out of the question, or in very young women.

PREGNANCY AND HEART DISEASE

Dr. A. RAE GILCHRIST read a paper on the relation between heart disease and pregnancy. He stated that heart disease was not a common complication of pregnancy, but that when it did occur it might well give rise to some anxiety on account of its relative infrequency in the individual practitioner's experience. That pregnancy threw an additional and progressively increasing burden on the normal heart was well known—a burden which was, as a rule, well borne, though in certain healthy women some dyspnoea on exertion and even slight oedema of the ankles was of common occurrence. Faced with pregnancy in a known cardiac patient, the practitioner's duty was to endeavour to form the most accurate prognosis. This involved the recognition of the possible dangers to the life or health of the mother during the pregnancy or labour, and also indeed in the days or months following delivery. A heart embarrassed by the strain of pregnancy or labour was productive of certain symptoms varying in the milder cases from a sense of exhaustion with slight dyspnoea, to fully developed heart failure in the most severe cases, with orthopnoea, generalized oedema, and increased venous blood pressure. Certain emergencies might arise during pregnancy or labour as a result of the sudden onset of auricular fibrillation with a high heart rate, of multiple infarctions in the lungs, of acute pulmonary oedema, or, finally, of collapse from acute cardiac dilatation. On the other hand, the prolonged additional burden of the pregnancy might make a further inroad into the cardiac reserve, with the result that after labour the response of the heart to exertion would be worse than before. Finally, were it considered desirable to empty the uterus artificially, then the obstetrician should act at the most suitable time and in the most appropriate manner, in order that the intervention in itself might be of minimal risk to a patient recognized as an impaired life.

Four years' experience of these cases at the Royal Maternity Hospital, Edinburgh, had led to the conclusion that no more accurate method of estimating the ability of these cardiac women to go successfully to term was to be obtained than by grading them according to the functional efficiency of the heart. The type of valvular disease, the etiology, and degree of cardiac hypertrophy, were in themselves of practically no help in forming a prognosis. The actual structural change in the heart mattered little. The all-important factor was the functional efficiency of the heart muscle, which could readily be assessed by observing the response of the patient to her everyday activities. In gauging the capacity of the cardiac patient to withstand the strain of pregnancy and labour, the functional classification of heart disease outlined by the New York Heart Association had proved to be of the greatest assistance. At the time of the first examination an attempt ought to be made to classify the patient according to one of the following groups. (1) Those who, though suffering from organic heart disease, were able to perform their habitual physical activities without any unusual distress, fatigue, or dyspnoea. These women were well enough for pregnancy and labour. (2) Those who could follow their usual activities, but had some slight discomfort in so doing. They had slight physical limitation, which showed itself by shortness of breath on climbing stairs, on walking uphill, or after performing household duties. Pregnancy and labour caused but little anxiety in these cases, though the timely use of forceps was indicated if the second stage was prolonged. (3) Those who had a definite limitation of physical activity, and were unable to carry out their usual duties without resting at intervals. Several halts were necessary in climbing a flight of stairs. They had given up attempting the more strenuous household work, and at night the ankles might be a little swollen. Seen before the sixth month with such symptoms, many of these women would require a Caesarean operation at or about term, depending upon the response they made to adequate medical treatment. Others developing such a grade of failure in the later months and with a satisfactory response to treatment would be able to deliver themselves spontaneously and without risk. (4) Those few whose cardiac reserve was minimal. They were unable to make any exertion without discomfort, and could at the most walk only a few yards with difficulty. They had a greater or less degree of congestive heart failure even at rest in bed. Women in this state were almost as certain to die if they went into labour spontaneously as they were if any obstetrical intervention was attempted before circulatory conditions were adequately treated. Heart failure of this extent in the first few months of pregnancy was probably unrelated to the demands of the foetus. A hysterotomy should be performed as soon as the woman was judged fit enough. In the later months this degree of heart failure could be avoided by adequate ante-natal care directed to improving circulatory efficiency. With this degree of failure, and labour imminent, energetic medical measures should at once be instituted. It was an axiom that no women should be exposed to the strain of active obstetrical intervention before every effort had been made to improve the circulation. Left alone, they might deliver themselves successfully and often prematurely; interfered with, they were almost certain to die, if not at the time of intervention then in the early days of the puerperium. Happily such cases were not very common. Of a series of 95 women who were carefully watched through pregnancy, labour, and the puerperium, 92 per cent. survived, and with more adequate supervision it ought to be possible to improve on this figure. The prospects of a woman delivering herself successfully at or about term were illustrated by the following figures: in Group 1, 84.6 per cent. accomplished this, the remainder miscarried; in Group 2, 77 per cent.; in Group 3, 55.6 per cent.; and in Group 4, 18.2 per cent. There were no Caesarean operations in Group 1; in Group 2 there were 7.7 per cent. (and these in the light of present experience had probably been unnecessary); in Group 3 there were 37.8 per cent., and in Group 4 54.6 per cent.

The question of a suitable anaesthetic sometimes arose. Dr. Gilchrist's view was that the anaesthetist was of more importance than the anaesthetic employed. Many of the cases were done under spinal anaesthesia with admirable results, but chloroform combined with oxygen seemed quite safe in skilled hands. Ether was doubly irritating to lungs a trifle congested, and gas, if productive of any cyanosis, embarrassed the heart by the ill effects of anoxaemia.

The Medical Research Council has issued as Report No. 62 of the Industrial Health Research Board, *Two Studies of Absenteeism in Coal Mines* (H.M. Stationery Office, 1s. net). The first of these is by H. M. Vernon, M.D., and T. Bedford, Ph.D., assisted by C. G. Warner, B.Sc. The second, by T. Bedford and C. G. Warner, deals with absenteeism at certain Scottish collieries, and an appendix by Professor E. P. Cathcart, F.R.S., and James Taylor, M.B., records an investigation into the possible causation of varying sickness rates in Scottish mines.

Reviews

FRACTURES

Dr. GEORGE EWART WILSON'S book on *Fractures and their Complications*[1] is the fruit of a wide experience, and is eminently practical in character. Being such, it has the defects of its quality in that it to a great extent ignores methods and theories which, although in favour with others elsewhere, are not approved by the author. Dr. Wilson relies, as a means of retention in position during union, almost entirely upon plaster-of-Paris, in the use of which he is a past-master, employing splints only in a few cases. Indeed, he goes so far as to say that for fractures of the extremities, omitting the Thomas splint, all the great variety of splints which have been used from time to time may be relegated to the scrap-heap. As for fractures of the shaft of the femur, he says that "there is one splint so much better than any other that it is the only one which it is necessary to keep in stock—namely, the Thomas splint." This he uses with weight extension and the Balkan frame. Although not in favour of plating fractures, Dr. Wilson employs ice-tongs for fractures of the femoral condyles, and sutures the patella and the olecranon process with wire or other material.

The subject of fractures has always been an important one—more so than some surgical authorities, too much occupied with other branches of surgery, have until lately realized. The vast increase in late years in the number of non-fatal accidents due to industry, and especially to transport, has tremendously enhanced the gravity of the problems involved, and many surgeons now devote their not inconsiderable ability to the study of the best means of rendering the results of treatment of fractures as nearly functionally perfect as possible. Among these means the *x* rays are of great importance. Surgeons like Dr. Wilson are no longer content to trust to *x*-ray records of the condition before and after setting of a fracture, or a mere fluoroscopic inspection. They insist on the importance of using the fluoroscope to guide their proceedings during the actual manipulations which are to result in the correct apposition of the broken bones. Dr. Wilson writes prophetically on this point:

> "The time is not far distant when it will be just as necessary to set most fractures by the aid of fluoroscopic vision as it is now considered obligatory to confirm the reduction by an *x*-ray."

But until the time when facilities for such vision are at hand in every hospital or clinic it is necessary to inculcate the best way of getting good results without it. This Dr. Wilson sets out to do, and succeeds in doing.

Among complications of fractures of the limbs ischaemic paralysis is one of the most disastrous and startling, both for the patient and for the surgeon, who may find himself adjudged liable to pay heavy damages in respect of an accident for which he is not to blame, simply because juries, and even judges, are found incompetent to estimate the value of pathological evidence. In this connexion Dr. Wilson quotes a rule which ought to be added to the collection of aphorisms in the *Illustrated Primer on Fractures* of the American Medical Association, and which applies to the danger of other conditions as well as ischaemic paralysis. Irremediable damage may be done in as short a space of time as six hours.

> "It is a safe rule that if the patient is not more comfortable after the fracture is set than before, there is something wrong, and it is the duty of the attending physician to find out what it is and to remedy it."

Differing from many previous writers Dr. Wilson holds that fracture of the neck of the femur is seldom the result of indirect violence, but that in the vast majority of cases it is caused by falling upon the trochanter. This is a question not easy of decision by statistical methods, because of absence of evidence as to whether in the process of falling the bone gave way before or after the ground was reached. Fortunately it is not of great practical importance. His prognosis in such cases seems to us more gloomy than is justified by the results of recent methods of treatment in this country. The few particular instances which we have quoted may be taken as evidence to show the general excellence of this book. It is freely illustrated by a large number of photographs, most of which are reproductions of *x*-ray plates and films. Many of these, though no doubt convincing in the originals, do not show up well in photographic blocks, necessarily reduced in size. We would suggest in a future edition the substitution of outlines for photographic reproductions, as more clearly demonstrative of the lessons which the author desires to convey. The index is inadequate. A much fuller one will be required by the student who in the future consults this book, and whom we forewarn that the absence of an entry in the present index by no means implies the absence of discussion of the subject in the text.

[1] *Fractures and their Complications.* By George Ewart Wilson, M.B., F.R.C.S., F.A.C.S. London: Baillière, Tindall and Cox. 1931. (Pp. viii + 415; 306 figures. 35s. net.)

MEDICAL PATHOLOGY

In *The Pathology of Internal Diseases*[2] Professor WILLIAM BOYD has attempted—and, we may say at once, with success—a book on applied pathology for physicians. Until now most pathological works have been "of such a form that the average physician seldom goes to them for assistance," or have been devoted to surgical pathology. This is to some extent due to the fact that whereas anatomy, pure and applied, must always be the basis of surgery, the physician has of late years turned more and more to the physiologist for assistance. That this tendency, if it involves neglect of the study of pathology, is not wholly to the good is readily seen by anyone who cares to read this book. Here the subjects are dealt with in a practical and readable manner, with a paragraph on "the relation of symptoms to lesions" at the end of each section, and the author's aim throughout appears to be the explanation of disease, its causes and symptoms, rather than the bald description of what will be found by the time the organs reach the museum. Though the work in no way pretends to deal with biochemistry or applied physiology, a sufficient discussion of these aspects will always be found where the occasion demands it.

There has evidently been some doubt in the author's mind in determining the exact scope of the work, which, although intended to be a companion to his *Surgical Pathology*, must obviously contain a certain amount of matter of use both to the surgeon and to the physician. It is stated in the preface, moreover, that the infectious fevers and conditions having no known morbid anatomical basis have been omitted, but we should have expected to find chapters on the pathology of bones and joints, and perhaps on intestinal parasites. One of the most notable features of the book is its fearless departure from conventional arrangement and classification wherever modern knowledge seems to indicate it. The sections on pneumonia and on diseases of the thyroid and the kidney perhaps show this to its greatest advantage. In discussing controversial matter the author does not profess to take up a wholly unbiased point of view, and there are therefore some opinions expressed to which all will

[2] *The Pathology of Internal Diseases.* By William Boyd, M.D., M.R.C.P.Ed., Dipl. Psych., F.R.S.C. London: H. Kimpton. 1931. (Pp. xvi + 888; 298 figures. 45s. net.)

not subscribe—for instance, that atheroma of the coronary arteries bears no relation to angina (especially as it is admitted that pain of the same type occurs in coronary thrombosis). In such matters, however, the opposing theories are always stated, and it is made quite clear that the opinion given is a personal one, so that the result is rather one of added interest and individuality which does not detract from the value of the book. Apart from such expressions of opinion, there are also a few statements made which seem to us definitely incorrect; for instance, that the clinical findings in second-stage (subacute) nephritis are identical with those of nephrosis, and that there is no retention of nitrogenous substances (p. 427). These are but a few flaws, however, in a book which on the whole is most commendable. Many of the descriptions of pathological conditions are among the clearest we have read. A textbook of pathology, moreover, which indulges on occasions in touches of real humour is a rare thing, and suggests that the author's own students are indeed favoured.

That the book is thoroughly up to date will at once be appreciated when we state that atelectasis and its relief by carbon dioxide are considered in relation to pneumonia; that peristalsis of the bronchi is mentioned; that tumours of the islet cells with hyperinsulinism are described; and that in the nervous diseases section Bailey and Cushing's work on cerebral tumours is fully discussed, as are also such subjects as post-vaccinal encephalitis and the most recent work on the etiology of multiple sclerosis. A useful bibliography at the end of each chapter contains most of the important literature, without attempting to give a complete list of the less significant papers. This, while no doubt the best selection for a general textbook of this type, is a little unfortunate when it has the effect of leaving out the works of some of the authors mentioned in the text.

EXAMINATION FOR LIFE ASSURANCE

The Conduct of Life Assurance Examinations,[3] by Dr. E. M. BROCKBANK, is divided into two sections: the first dealing with the routine examination and the filling in of the medical report form, while the second is devoted to a brief discussion of the influence of various impairments on the assessment of the risk. As the volume is one of a "General Practice Series" it may be assumed that its chief purpose is to help the practitioner in his duties as a local examiner. This being so, Dr. Brockbank rightly insists on the importance of the medical report being as detailed as possible in any case of impairment, so as to give the head office officials the utmost help in enabling them to arrive at a just estimate of the extra risk. The actual classification by the medical examiner is of secondary importance; the inclusion of all the relevant facts in the report is the touchstone of its value to the assurance company.

On the whole, it may be said that Dr. Brockbank's book will be helpful to the general practitioner chiefly in indicating the point of view required in life assurance work, which is naturally rather different from that of ordinary clinical practice. The text contains, however, various statements which seem difficult of acceptance. Thus, in a case of glycosuria, it is suggested that the subject should be asked to avoid "all carbohydrates and sugar" for twenty-four hours, and then to come up for re-examination. "The urine then tested may be free from sugar; but in a real diabetic case it may contain some, as the sugar is made in these people from proteins of the food and from their own tissues." Surely many diabetics of moderate grade would be sugar-free under these conditions, and their acceptance at ordinary rates, as is implied in the context, would hardly commend itself as sound business. Again, the suggestion, on the strength of an extra mortality of 10 per cent., in an American investigation, that "a blood pressure of 140 mm. is dangerous," pays too great a tribute to the infallibility of statistics, and is contrary to the opinion of most experienced physicians. In connexion with this subject, on page 69 appears the statement: "In the healthy American students in 13 per cent. of the observations the diastolic pressure varied from 40 to 80 mm., with an odd case of 90 mm.; the greatest number was about 45 mm." On page 81 we read: "If the patellar reflex is abnormal or different on two sides general paralysis must be suspected and the foot reflexes examined as well as the pupil." Statements such as these seem to call for amendment in the next edition of the book.

[3] *The Conduct of Life Assurance Examinations*. By E. M. Brockbank, M.D., F.R.C.P. The General Practice Series. London: H. K. Lewis and Co., Ltd. 1931. (Pp. viii + 173. 7s. 6d. net.)

EXPERIMENTAL PHYSIOLOGY

Dr. F. W. LAMB'S *Introduction to Human Experimental Physiology*[4] opportunely appears at a time when the methods of teaching medical students are receiving a good deal of critical attention. The book describes in detail the practical exercises which are carried out in the physiological department of the University of Manchester; these do not deal with the whole of the subject, but only with the blood, circulation, and respiration. The ground covered is therefore not so extensive as that of Douglas and Priestley's well-known *Human Physiology*, but Dr. Lamb's work is more ambitious in character, and the course he outlines could probably only be carried out in its entirety by honours students who can devote an additional year to the study of the subject. Many alternative procedures are considered, and it is presumably left to the discretion of the teacher to select those which are best adapted to the facilities of his laboratory and the capabilities of his students. The practical directions are admirably lucid and complete, and draw attention to the various sources of error which must be avoided. A full list of references is appended to each section, and this should prove of great assistance to the senior "science" student. The descriptions of the exercises are very wisely accompanied by a fairly detailed account of their theoretical implications; for example, a good account is given of the regulation of blood reaction and of van Slyke's work.

Professor A. V. HILL, in his cogent introduction, emphasizes the great importance of human experimental physiology in the training of students of medicine. It is far easier to interest students in physiology when they are working on themselves or their friends, and when such interest has been aroused much better results are obtained than when the practical exercises are regarded as a useless and meaningless drudgery which has to be suffered in order to satisfy unreasonable teachers—as was not infrequently the case with some of the experiments in frog nerve-muscle physiology. Most of the fundamental facts of physiology can be rediscovered and demonstrated on man; the student can learn that his own healthy normal body is one of the most experimentable objects in the world, and by its intensive study he can obtain an idea of the normal, which is so vitally important but often so sadly lacking in those who study disease. We are in hearty agreement with Professor Hill that Dr. Lamb should further increase our indebtedness to him by preparing an equally good second volume, dealing with the special senses, nutrition, and certain aspects of the nervous system.

[4] *An Introduction to Human Experimental Physiology*. By F. W. Lamb, M.D. London: Longmans, Green and Co. (Pp. xii + 335; 59 figures. 12s. 6d.)

DISEASE IN CHILDHOOD

In his *Handbook of Diseases of Infants and Children*[5] Dr. F. M. B. ALLEN has provided a comprehensive but compact survey of the subject. The book is designed for the use of students and practitioners, and should prove equally useful to both; it replaces the original volume in the series by the late Dr. McCaw, and recent advances in paediatrics have made it possible to include much new material. The arrangement is clear and the printing excellent. After an introductory chapter on conditions and diseases of the newborn, Dr. Allen discusses infant feeding at great length, and covers the wide field of modern opinion on this subject with admirable clearness. Chapters on nutritional disorders, deficiency diseases, and alimentary disturbances follow, and a chapter is devoted to diseases of the peritoneum and liver. Affections of the nose, nasopharynx, and larynx are discussed, and diseases of the respiratory system are considered in detail. It is perhaps unsatisfactory that the chapter on rheumatism and chorea should follow, instead of precede, the chapter on diseases of the circulatory system; but this is a minor point of arrangement. The remaining chapters are concerned with genito-urinary diseases, syphilis, diseases of the nervous system, mental deficiency, the myopathies, blood diseases, and general conditions such as achondroplasia and Still's disease. The appendix contains a few useful recipes for preparing food, some observations on diagnostic methods, and tables showing the development of the special senses, average heights and weights at different ages, and dentition ages. A collection of prescriptions is included. Dr. Allen has purposely "avoided theories as far as is compatible with an intelligent understanding of the subject"; although, perhaps, he has avoided too much, as, for example, in his table for the diagnosis of jaundice in the newly born. On the whole, however, he has presented the subject of children's diseases with freshness and without prolixity. In his chapter on alimentary diseases he has perhaps over-emphasized the importance of summer diarrhoea, a condition which is rapidly disappearing in this country. For the treatment of enuresis and habit spasm he puts forward practical suggestions which are not found in the usual textbooks. The absence of illustrations is to be regretted.

NOTES ON BOOKS

The volume of the Practical Medicine Series on *General Surgery*,[6] edited by Dr. EVARTS A. GRAHAM, contains, as in previous years, an excellent account of the progress made in all branches of surgery. The subjects which receive special notice are anaesthesia, attention being drawn to the dangers attending the use of some of the barbituric acid compounds, sympathectomy in circulatory diseases, the surgical applications of therapeutic venous obstruction, hyperparathyroidism, the treatment of empyema, and appendicitis.

The eighth edition of *Bell's Sale of Food and Drugs*,[7] prepared by Mr. R. A. ROBINSON, is much more comprehensive in scope than its predecessors, and will be found a very serviceable guide to the interpretation of the Food and Drugs (Adulteration) Act of 1928, the various Acts dealing with milk and cream, and the numerous Regulations and Orders affecting the quality and composition of food, or prescribing methods of labelling. The statutes are well annotated and arranged in chronological order, and the statutory Regulations and Orders are classified in groups. A convenient summary is given of the powers and duties of local authorities, and much useful information has been gathered together in the appendices, including a bibliography of official publications, a selection of Government circulars, and chemical notes on common forms of adulteration.

The publication of a biography of *Francis Blight, Publisher*,[8] who was chairman and managing director of Messrs. Charles Griffin and Company for nearly thirty years, will give satisfaction not only to his many personal friends, but to those who have followed the work of this firm since it became a company in 1891. The present sketch has been prepared by the Rev. GEORGE HAWKER, and is prefaced by some introductory notes in which Mr. Blight traces his Devonshire ancestry. Much of Mr. Blight's publishing life—from which he retired in 1927—was devoted to the popularization of technical learning, a task for which he was unusually well equipped by his early training as an engineer and surveyor, and by his association with the publishing house of Messrs. J. and A. Churchill. In recognition of his services to technical literature Mr. Blight was elected a Fellow of the Royal Society of Edinburgh in 1918.

Though our profession can claim several poets of the first order, occasional verses by medical men are too often disappointing, and more particularly so when they touch on scenes of medical life. Dr. ALAN MCGLASHAN'S collection of short poems, *St. George and the Dragon*,[9] appears to us to be much above the average, and to hold out promise of future achievement. The author has a sensitive mind and a delicate ear for rhythm. On the whole, his emotion rings true, and he expresses it in language that comes only to the loving student of great poetry. His hospital pieces are uneven: "The Last Visit" is as good as "Post-Mortem" with its forced realism is bad. Among the Hebridean lyrics we would give very high marks to "After the Storm."

PREPARATIONS AND APPLIANCES

"SUNSHINE" LAMPS

We have received from the Thermal Syndicate Limited of Wallsend-on-Tyne particulars of their vitreosil "sunshine" lamps, in which an endeavour has been made to approximate to sunshine by balancing the blue-green of the mercury arc with the yellow and red of the gas-filled filament. It is not pretended that the solar spectrum is exactly reproduced, or that the light is suitable for such operations as colour-matching, but it is claimed for the lamp that it gives an effect comparable physiologically with that forthcoming from sunlight. The lamp consists of a quartz mercury vapour burner of vitreosil (pure fused silica), together with two supplementary filament lamps mounted inside a diffusing and filtering globe of the same substance. The bowl filters out the extremely short ultra-violet rays of the mercury vapour, and allows the longer ultra-violet to pass freely, while the supplementary lamps compensate for the unpleasant colour of mercury vapour, and represent the warming and enlivening component of sunshine. The lamps are intended for general use in workrooms and offices, and for the house.

SODIUM MORRHUATE FOR INJECTION OF VARICOSE VEINS

Messrs. Burroughs Wellcome and Co. have introduced "hypoloid" sodium morrhuate as a sclerosing agent for the treatment of varicose veins. The systematic effects of intravenous injections of sodium morrhuate were investigated some years ago, and the remarkable power of the drug to sclerose veins was at once noted. Sodium morrhuate is stated to be innocuous to the subcutaneous tissues, thus reducing the risk of an "injection ulcer" to a minimum; its non-toxicity allows it to be administered in large doses. The drug is supplied in 2 c.cm. ampoules containing a 5 per cent. solution. The treatment recommended is to give a series of injections of 1/2 to 1 c.cm. of the 5 per cent. solution. This treatment can be repeated after a week's interval.

CONFERENCE ON MENTAL HEALTH

THE HUMAN FACTOR VARIOUSLY CONSIDERED

The National Council for Mental Hygiene held its second biennial conference from May 27th to 29th, at the Central Hall, Westminster. About eighty bodies, including the British Medical Association, co-operated. The subject chosen for discussion was about as wide as any subject could be—namely, "The human factor"—which was considered at successive sessions in its relation to international problems, to crime, to industry, to social services, and to education. Speakers, therefore, were tempted to roam over the whole field of human affairs, and some of them took full advantage of the liberty.

The conference was opened by Miss SUSAN LAWRENCE, M.P., Parliamentary Secretary to the Ministry of Health, who mentioned with gratification that since the previous conference the Mental Treatment Act, then foreshadowed by the Minister, had come into being. Previous legislation, she said, had been devoted to preventing the consequences of mental disease, and the idea of the safety of the community and of the patient had been the governing consideration; but now for the first time the emphasis was laid upon the possibilities of treatment and prevention. Miss Lawrence incidentally paid a high tribute to the medical profession. The politician, she said, was rather distrusted, and the press had lost a great deal of its former power, but there was one person—namely, the doctor—to whom the layman listened with respect and attention, and with an implicit belief in what he said. However sceptical the British public might be in other matters, it was extremely docile in accepting the views of medical science, and in that way, she generously declared, it showed its intelligence. The people did believe in science, and were perfectly ready to submit themselves in health matters to the judgement of experts.

The conference then resolved itself into a kind of peace meeting, and discussed the human factor in international problems. Dr. J. R. LORD, a member of the executive council of the International Committee for Mental Hygiene, spoke of the part which mental hygiene—the greatest constructive force in the world, leading, as it did, to an understanding of human nature and behaviour—could play in the avoidance of war. One point he brought out was that the mental hygiene movement, hardly known as an international movement before the war, now embraced some thirty-five societies in different countries. A suggestion made by Dr. Lord was that princes in the succession in monarchical countries should have psychiatrists in attendance, and also, of equal importance, that in democratic countries measures should be taken to ensure the mental health of high officers of State, especially those occupying executive positions.

The meeting was also addressed by Professor A. ZIMMERN, until lately deputy director of the League of Nations Institute of Intellectual Co-operation, and now professor of international relations at Oxford. Dr. Lord had described the League of Nations itself as a vast experiment in mental hygiene, and Professor Zimmern instanced some of the great services of the League from this point of view. Not the least was the fact that it had concentrated in one place the handling of complex and technical international business, and had arranged for open discussion, by which the public of different countries was being educated as to the nature of the issues. Thus the gulf was bridged between romance and reality, which had hitherto so greatly impeded the sober discussion of international problems.

At the session devoted to the human factor in crime, over which Sir HUBERT BOND presided, Dr. W. A. POTTS, psychological expert to the Birmingham justices, spoke of the need of investigation into the history of delinquents and the difficulties and handicaps of their lives. An appreciation of those difficulties was assisted by realizing the interrelation of mind and body, which was so close that physical disorders might often cause abnormal conduct. Mr. CLIFTON ROBERTS of the Howard League for Penal Reform, suggested that perhaps some enlightened member of Parliament might introduce legislation by which, in future, criminals would be described as patients, and prisons as institutions for the scientific treatment of offenders.

A discussion on the human factor in industry was opened by Sir DAVID MUNRO, secretary of the Industrial Health Research Board of the Medical Research Council, who described vocational tests; there was as yet, he said, no reliable test for temperament, the most important feature of the make-up of the human mind, unless the tests by Drs. Culpin and May Smith in their work on "The nervous temperament" proved to have universal application. Mr. C. J. BOND also mentioned experiments in vocational guidance carried out by the National Institute of Industrial Psychology. He believed that vocational guidance on the one hand, and vocational selection on the other, would grow in usefulness as they became more fully developed, and might rank in the future among the important influences helping to restore prosperity and contentment to industrial life.

The DEAN OF ST. PAUL'S presided over the session which discussed the human factor in social services, and made a plea for greater attention to eugenics. Perhaps the greatest problem for the educationist to-day, said Dean Inge, arose out of the very low average level of intelligence. The Americans applied scientific tests to over a million of their recruits in the war, with the disconcerting result that the average mental age of the American citizen was discovered to be 13—and the Dean supposed that on this side of the Atlantic it would not be any higher. In the past the progress of a nation or tribe had depended less on the raising of the average of intelligence than on its variability, whereby a few highly gifted leaders were thrown up. But average ability was now coming to be of greater importance.

Dr. H. CRICHTON-MILLER, honorary director of the Tavistock Square Clinic, discussed with frankness the problem of the marital relation. He said that monogamy, which had been the accepted ideal of Christian civilization for many centuries, and was much older than Christianity, of course, was now threatened in a way which to some of them appeared alarming. The question was how, by taking thought, one could make any difference to the amount of maladjustment which was so evident. In the view of the psychologist, the Church had made the situation more difficult by demanding certain commitments in the name of monogamy which were not psychologically possible. The Church had acted quite naturally and rightly from its own point of view, but it had neglected the fact that while behaviour could be commanded, feelings could not be commanded, and because human beings could not command their feelings they had no right to make them the subject of solemn pledges. Dr. Crichton-Miller, however, thought it a proper line of argument that for this very reason, because emotional feelings could not be pledged beforehand, the relationship should be all the stronger on the behaviouristic side, and conduct must be all the more necessarily pledged. The guiding consideration always should be posterity. All the difficulties of the marital relationship ought to be subordinated entirely to the trusteeship of parenthood. By so doing we should get away from "this froth and bubble about companionate marriages."

Another speaker was Dr. ISABEL G. H. WILSON, Commissioner of the Board of Control, who discussed in a happy way the different types and motives of social workers, calling for sympathy and understanding of all types, even including those who "always wore a halo round their heads." The closing session was a very domestic affair, with a discussion on the bringing up of children, in the course of which the one medical speaker, Dr. F. C. SHRUBSALL, uttered some home truths in child psychology, such as, for example, that a nagging household produced an irritable child, and that it was useless to recommend to a child a course of action which was not practised in the family.

SURGERY AND DIET

For three decades and more surgeons have been applying their art to diseases and disorders which formerly fell within the purview of the physician. Are physicians to turn the tables on surgeons and demonstrate that many—if not most—surgical disorders are preventable? The mass experiments described by Colonel Robert McCarrison in two lectures recently given at the Royal College of Surgeons of England, the second of which appears in our present issue, prove beyond cavil that rats, improperly fed, become liable to many of the surgical diseases and disorders to which human flesh is heir, while the same stock of rats, properly fed, retain perfect health. Coming after the brilliant Hastings Lecture,[1] so recently delivered by Professor Edward Mellanby, the results now published by Colonel McCarrison, based as they are on a quarter of a century of systematic and persistent inquiry, give the surgical mind matter for its most serious consideration. We are passing from a period in which bacteria were held of more surgical importance than diet, to one in which a knowledge of diet is to be regarded as more important than a knowledge of bacteria. It is the physician or dietitian who is leading the way. Who would have thought, ten years ago, that an error in diet would render us liable to such diverse conditions as middle-ear disease, duodenal ulcer, renal calculus, or cystitis? Yet that is what all recent experiments in diet go to prove. It does seem as though the physician is again to come into his own. The surgeon of the future, it now appears, will have to be a master of dietary as well as a skilled operator and diagnostician. A full knowledge of foods may be the key not only to prevention, but also to cure.

Professor Edward Mellanby ascribes to vitamin A, which most of us obtain from the milk, butter, eggs, and green vegetables we consume, the chief role in safeguarding the body from surgical infections; and of this view readers of Colonel McCarrison's lectures will find the strongest confirmation. Historically it would be more just to say that the results now arrived at by Colonel McCarrison are a confirmation of a conviction which was forced on him by experiments he carried out in 1913–14, just before the great war. Sir Frederick Gowland Hopkins had by then demonstrated that certain "accessory food factors" were necessary to growth and to health; McCollum, Davies, Osborne, and Mendel had entered the field of inquiry, and were separating one factor from another. It was while McCarrison was at work on goitre that Casimir Funk gave the name "vitamin" to accessory food factors, and threw out the hint that they might be akin to substances formed in the glands of internal secretion. Just then McCarrison, as a result of ten years of inquiry, had succeeded in producing goitre and cretinism under experimental conditions. Turning aside to ascertain the effect produced on the thyroid by an imperfect dietary, he fed pigeons on milled rice. It was not, however, the effect on the thyroid that impressed him, but the liability of the birds thus fed to become subject to infections. Pigeons given a normal diet, he found, were almost free from infection. The deduction he drew from his early experiments was this: "Appropriate food is thus shown to afford protection against the invasion of the body by—or the growth therein of—certain highly virulent organisms."[2]

Colonel McCarrison was himself the first to demonstrate the extent of the damage wrought in tissues and organs of the bodies of animals which had been fed on deficient dietaries. Resuming his investigations after the war, a spare laboratory was assigned to him in the Pasteur Institute which Lord Curzon had established in the Nilgiris, Southern India, for the treatment of rabies. He equipped his laboratory, trained a native staff of assistants, raised a stock of rats, and proceeded to carry out dietetic experiments on an extensive scale, being still an officer in the Indian Medical Service, attached to the Foreign and Political Department. He was not content merely to note the effects of selected dietaries on the growth of his animals, but undertook a minute and systematic examination of their bodies to find out what had happened to their glands and internal secretions, and to what extent they had become subject to infection. It was while carrying out these examinations that he was struck by the gross changes which had occurred in the lining membrane of the whole alimentary tract; the epithelial lining, especially that concerned in the secretion of mucus, was manifestly in an unhealthy state. The changes he observed were almost identical with those which occur in the human great bowel in cases of chronic colitis and stasis. He found similar changes in the lining membranes of the respiratory, urinary, and genital tracts of animals long subjected to deficient dietaries.[3] From these observations he inferred that devitaminized foods or unbalanced diets broke down the epithelial defences of the body, and thus rendered the animals experimented on liable to infection. Quite independently, Dr. W. Cramer, working in London, observed the profound changes undergone by the intestinal epithelium and lymphoid tissue in rats deprived of certain food factors.[4] The researches of Dr. S. Mori (1922), Drs. Wolbech and Howe (1925), and of Mellanby and Green (1928) proved that a sufficient supply of vitamin A was necessary to maintain the epithelial systems of the body in a state of health. Colonel McCarrison and Dr. Cramer attribute the sole "anti-infective" action of vitamin A to its maintenance in health of the epithelial linings and intestinal tissues of the body. Indeed, Colonel McCarrison, in the lectures just published, goes further,

and claims that the defensive mechanism of the body may be injured by any improper mode of feeding. To place the living body in the best position to resist the infections to which it is at all times exposed it must be supplied (1) with a due allowance of all accessory food factors ; and (2) with all necessary inorganic ingredients —calcium, phosphorus, iron, and iodine. These must be properly " balanced," not only with each other and with the essential vitamins, but also with the carbohydrate and protein substances included in the dietary. Probably there is an optimum " balance " for each individual human being, which changes with each decade of life.

It is this promising but complex field of research, one which seeks for protection against medical and surgical ailments in a better knowledge of dietetics, that is now being opened up, and to which the lectures just given at the Royal College of Surgeons by Colonel McCarrison make so valuable a contribution. Especially is the work he is doing of the utmost significance for the health of millions of our fellow subjects in India.

THE PROMISE OF YOUTH

The third volume of the remarkable series *Genetic Studies of Genius*[1] has now appeared, and in it Professor Terman and his associates carry a stage further the arduous and fascinating task that they have set themselves. The study originated with the careful selection of 1,000 exceptionally gifted children in California. The children of the gifted group were included well in the top 1 per cent. of school children. Most thorough investigations of all kinds were carried out on these children, including anthropometrical measurements, health data, intelligence, personality, and other psychological tests, studies of heredity and human conditions, and other factors too numerous to mention. The result was the first volume of the series, which was reviewed in our columns four years ago.[2] The second volume recorded the results of the study of the early mental traits of 300 geniuses of all centuries.

The present volume is a sequel to the first, and is largely concerned with a complete re-testing and re-examination, after six years had elapsed, of the gifted children originally studied. In general the earlier promise has been fully realized. For example, boys of the gifted group attending Stanford University reached a scholarship average slightly above that of Stanford freshmen. This is a remarkably good result, because the selection of Stanford students is stated to be so rigorous that the gifted children are competing with students whose level of ability is little lower than their own, and who are nearly two years older on the average. The proportion of the group who have graduated from Stanford " with distinction " or " with great distinction " is more than double the average for Stanford students generally. A repetition of the intelligence tests shows a certain fall in the intelligence quotient, and this fall is quite large in a small proportion of cases. It is particularly interesting that in the cases where a marked fall has occurred no connexion can be found with health, with personality traits—that is, poor balance or undesirable social attitudes—with race, or (most remarkable of all) with environmental conditions. The suggestion is advanced that fluctuations in the intelligence quotient (or I.Q.) are reflections of changes in the rate of mental growth, and are in all probability inborn. It is also shown that the earlier test is the better index of inborn ability. The authors hope to follow up their group at further intervals, and it will be very interesting to observe whether these changes in I.Q. are temporary or permanent. Once again the normality of the gifted children from the point of view of social and personality traits is emphasized. The health history appears to have been good. In the earlier study it was recorded that the gifted group on the average had much more sleep daily than unselected children, and although the difference is now somewhat less they still sleep more than unselected children at all ages up to 17.

The original study was one of unique value and importance as a record of actual data that might replace hazy impressions and prejudices, and the present volume is essential as a further instalment of the original plan. But it possesses in addition a special and human interest that makes it a most attractive volume for the general reader. Selected case histories are given, and it is impossible not to comment on the humanity with which these are written. The cases quoted in the chapter entitled " The conquest of obstacles " form an appealing record. The third part of the volume is a study of literary juvenilia. A tentative scale for assessing their merit is proposed, and the whole section is fascinating. We wish that there were space in which to quote some of the remarkable exploits of these infant prodigies. For example, " Millie," who at the age of 26½ months extracted the greatest enjoyment from reading, and had a reading vocabulary of 700 words. But if we had to pick a favourite we think our choice would fall on " Verda," a girl of strongly marked literary abilities. Her first poem was composed at the age of 2 years and 9 months, and records her reaction to the effects of a double mastoid operation. At the age of 5 Verda composed a remarkable poem, which she printed without any spacing between the words. It is not surprising to learn that her subsequent progress was phenomenal. At the age of 11 years and 7 months her I.Q. was 186, which places her among the foremost members of the gifted group. At the age of 16 years and 4 months her score on the Thorndike test was 109, which is said to be one of the highest scores on this test ever made by a woman. At 17 she entered college, and her college career has been one of unbroken success.

The authors trust that it will be possible to re-examine the group after an interval of another ten or fifteen years. We hope that this will indeed be done. In the meanwhile, the present record is of the greatest interest and value.

LONDON'S NEW UNIVERSITY BUILDINGS

Lord Macmillan, who presides over the Court of the University of London, addressed the Royal Institute of British Architects a few days ago, and in allusion to the imminent development of the Bloomsbury site for university purposes, described it as an interesting adventure, which he was sure would be carried to an outstanding success. The University of London, he said, was embarking upon an architectural scheme which would alter the aspect of the centre of the capital, and he believed that within the time of most of those present there would be completed an architectural group worthy to be named with any of the monuments of antiquity. Lord Macmillan confessed that while he believed in the art of ancient times, he thought each generation was inclined to belittle itself in marvelling at the achievements of the past. He was sure that British architecture of the present day could supply the University of London with a worthy home. A day or two after Lord Macmillan had spoken, the name of the architect chosen by the Court was announced, and further particulars, officially supplied, will be found at page 1044. The work is to be entrusted to a single architect—namely, Mr. Charles Holden of London, who has been responsible for many works of beauty and distinction. The best known is the building which houses the headquarters operations of the Underground Railway at St. James's Park, where Mr. Holden has shown his skill in dealing with a closely surrounded site. At Bloomsbury he will have the advantages of an open site of ten acres, with fine surroundings, including some buildings of a university character. The work is expected to occupy from twenty to thirty years, and to cost between £2,000,000 and £3,000,000, but the architect is to prepare at once a general design for the whole of the site so as to ensure that the work shall proceed upon harmonious lines. It is quite possible, of course, that during the next generation the character and compass of university teaching will be greatly altered, and sufficient margin is to be left for additions and modifications to meet academic needs as yet unforeseen. The site of this great building scheme extends from Montague Place on the south, opposite the north façade of the British Museum, almost to Euston Road on the north. On the west side it extends for the whole length of Malet Street, on which the London School of Hygiene and Tropical Medicine has a frontage, and on the east side the line of the site runs through Russell Square, Upper Montague Street, and Woburn Square. Torrington Square (so miscalled, for it is really a wide avenue) runs through the centre of the site, and there is some idea of keeping this as a garden space, so as to give the enclosure something of the quietness and atmosphere of the Temple or Lincoln's Inn. A plan of the site and an air photograph were reproduced in an article on the future of the University of London, published in these columns four years ago.[1] The house of the British Medical Association, in Tavistock Square, is two or three minutes' walk from the north-east corner of the site, and University College Hospital about the same distance from the north-west corner. The first part of the site to be developed will be the land, already vacant, at the southern end, where the administrative block of the University will be erected, also the University hall and library.

REPORTS OF THE PHARMACOPOEIA COMMISSION

Our readers will be aware that a new edition of the *British Pharmacopoeia* is in preparation. The General Medical Council is now publishing reports embodying the conclusions of the subcommittees which have carried out much of the work of revision. The report by the Pharmaceutical Chemistry Subcommittee[2] deals chiefly with the tests for purity of drugs. This is of necessity a highly technical document, but the reliability and accuracy of these tests is of great importance, in the first place for the safeguarding of patients, and secondly, because the *British Pharmacopoeia* is a presumptive legal standard. It is a well-known fact that in many cases in the past the standards adopted by the leading drug firms for certain drugs have been in advance of the standards laid down by the *Pharmacopoeia*, and the medical profession will be glad to learn that it is proposed to formulate official and adequate standards of purity for such drugs as the following: anaesthetic ether, chloroform, nitrous oxide, oxygen, barium sulphate, and carbon tetrachloride. In all these cases a high standard of purity is essential for the safety of the patient. Another report has been issued simultaneously by the "Cod-Liver Oil Colour Test Subcommittee."[3] This subcommittee found that the blue colour test for the vitamin A content of cod-liver oil gave variable results with different workers, and has laid down standard conditions, which will ensure uniform results. It also suggested a suitable lower limit for the vitamin A content in cod-liver oil. The Pharmacopoeia Commission has, however, decided not to impose a test for the vitamin D content of cod-liver oil, because almost all samples contain enough vitamin D for therapeutic purposes, and it considers that the biological test for vitamin D—the only one available—is so expensive and time-consuming that it ought not to be imposed unless absolutely necessary. The commission is, however, considering the official adoption of the unit laid down by the Medical Research Council for vitamin D. The official adoption of this unit would be a great service, for it would encourage uniformity in the description of the vitamin activity of cod-liver oils sold in this country. As was mentioned recently in these columns[2] the Norwegian unit works out at less than half the British unit, and this diversity is unfair to the Empire products.

SILICOSIS IN SOUTH AFRICA

An authoritative expression of the South African teaching on silicosis has long been desired, and the admirable account just received[1] will be eagerly welcomed by all workers on the subject. It consists of three papers presented at a meeting of the Transvaal Mine Medical Officers' Association, held in Johannesburg in October last, and published as a special supplement to the *Proceedings* of the association. The first paper, on the histo-pathology of silicosis, is by Dr. F. W. Simson of the Department of Pathology of the South African Institute for Medical Research, Johannesburg.

[1] Published by Authority of the General Medical Council, 44, Hallam Street, W.1. (3s.)
[2] *British Medical Journal*, May 16th, 1931, p. 853.
[3] *Proceedings of the Transvaal Mine Medical Officers' Association*. A Symposium on the Histo-Pathology, Pathological Anatomy, and Radiology of the Disease. Johannesburg, October 23rd, 1930. Issued by the Association, Chamber of Mines Building, Box 809, Johannesburg.

The anatomy and lymphatic apparatus of the lung are first discussed, and the author advances the view, based on the study of lungs from cases of "status lymphaticus," that lymphoid tissue occurs in the lungs only in direct relationship to the air passages and their terminations, and not, as is generally held, in association with blood vessels. A brief account of the fibrosis caused by dusts other than silica is followed by a description of the formation of the specific silicotic lesion—the silicotic islet. The author considers that there is a type of pure silicosis which can be shown by biological tests to be free from any association with tuberculosis. He also recognizes a form of "infective silicosis" in which the infective agent is usually the tubercle bacillus, and describes the mode of origin of the lesions. The second paper, on the pathological anatomy of silicosis, is by Dr. A. Sutherland Strachan. While denying that lymph stasis due to the involvement of the mediastinal lymph nodes is a necessary precursor of pulmonary silicosis, Dr. Strachan draws attention to the importance of silicosis of the thoracic glands, which may secondarily involve the oesophagus and the bronchi. In this paper, again, the importance of infective silicosis is emphasized. The third paper, on the correlation of the pathology, radiology, and symptomatology of silicosis, is by Dr. L. G. Irvine, chairman of the Miners' Phthisis Medical Bureau. Starting with a review of the pathology of the disease as described in the previous papers, Dr. Irvine discusses the clinical manifestations of the various stages of the disease, and the appearances seen in the corresponding radiographs. The classification of the radiographs adopted by the Medical Bureau and their interpretation are dealt with in detail, and the paper concludes with a section on the legal aspect of diagnosis, incidence, and prognosis. The volume contains a beautiful series of thirty-two plates illustrating the morbid anatomy and histology of the disease, and representative radiographs.

OPHTHALMOLOGY IN EGYPT

The fourth annual report of the Giza Memorial Ophthalmic Laboratory in Cairo[1] is a good indication of the type of work which is now being carried on in Egypt. As might be expected, attention is largely focused on the problems of trachoma. During the last year the staff of the laboratory has carried out much patient work on the subject of the etiology of the disease, and while the results have been largely negative, the matter is of such extreme importance to the country that every effort must still be directed towards the elucidation of its special problems. Further observations have been made on the occurrence of lesions simulating trachoma in monkeys. The report states that it is important to note whether the follicles seen on the conjunctivae of these animals rupture spontaneously or require to be expressed, for it is this feature which distinguishes the follicles of trachoma from those of other follicular diseases of the conjunctiva. Three different strains of *Bacillus granulosis* of Noguchi were received from the Rockefeller Institute, New York. These were found to agree in all their reactions with those described by Noguchi. But experimental inoculations, following exactly the technique of this worker, were entirely negative, even after periods extending to six months. Following the inoculation all the animals developed a slight congestive reaction which rapidly disappeared. Nearly all presented one or more scattered translucent follicles, and when the eyes were examined very carefully with the corneal loupe, pinpoint follicles were visible along the upper edge of the tarsus; there was, however, an entire absence of all inflammatory signs. One experiment was made upon a human subject. The conjunctiva of a blind eye, which had traces of healed trachomatous infection, was inoculated with *B. granulosis*. The patient was watched for two months, but no signs of recurrence of the disease appeared. This is in marked contrast with the effects of an accidental infection. A doctor, when expressing trachoma follicles from a patient, received a splash of the material in his eye. Despite the fact that the eye was immediately bathed, there was a slight discharge two days later, and on the fourth day the palpebral conjunctiva was acutely congested. By the eighth day follicles appeared on the upper border of the upper tarsus, and on the eighteenth day they had covered the tarsus. The whole conjunctiva was acutely injected. Despite the fact that active treatment was carried out from the beginning, there was still chronic congestion after ten months. Until now, statistics of the eye conditions of the population of Egypt have usually been compiled from figures obtained from the Government ophthalmic hospitals, from school clinics, and from census returns, but never before has the whole of a village been examined. This year a typical Egyptian village was chosen for investigation. Bahtim has a total population of 3,549, of which 3,058 were investigated. Excluding 139 infants under 1 year, the remainder were found to have trachoma, in one stage or another, except for one marasmic child, aged 1. It was evident that the people became infected with trachoma very early, the largest proportion in the first year of life. There is a great and early tendency for the trachomatous process to cure itself by cicatrization. The active and most infective stages of trachoma are rarely seen in adult life. Complete spontaneous cure without complications is not very common, although it is remarkable to note the early age at which this sometimes occurs. The incidence of acute mucopurulent conjunctivitis was also noted. This was relatively rare after childhood, the probable explanation being that in patients of 10 years of age scar tissue has largely infiltrated and replaced the normal conjunctival mucosa. Of the 139 infants under 1 year only 19 were found to have normal conjunctivae; none were found normal after the second month of life. Nearly 40 per cent. had acute conjunctivitis, and these patients were entirely neglected. Superstition is partly responsible for the neglect; this emphasizes the great need for education, without which no real improvement can be expected. Trichiasis was found in 21 per cent. of the inhabitants as the result of trachoma; 5.59 per cent. were blind in one eye, and 1.05 per cent. in both eyes. The standard was severe—namely, inability to count fingers at a distance of one metre. Acute ophthalmias and their effects accounted for 75 per cent. of the blindness. The report accentuates the fact that the findings of the

[1] Schindler's Press, Cairo. 1930. (Pp. 138; 16 plates.)

examination of this village are of more than local interest. The village is typical of the greater part of Egypt, and it is stated that what was found in that small place is true for the whole country. The inevitable conclusion is that a great amount of the blindness in Egypt may be, and can be, prevented if treatment is sought early. There are some interesting reports of investigations into novel forms of treatment of trachoma. Intravenous injections of copper salts were tried, but their effects were uncertain. There was possibly some beneficial effect on the acute signs, but the more chronic symptoms were not relieved. In one case there was improvement in one eye, but there was a recurrence in the other during the treatment. Phenolaine, for which startling claims have been made, was not found to possess any definite advantages over such remedies as yellow oxide of mercury and dionine in clearing corneal nebulae. Further, the method is laborious, and is sometimes followed by unpleasant after-effects which are otherwise never seen. Consideration is given to the possible explanation of these divergent findings. One source of fallacy is the testimony of the patient himself. He may fancy his vision has been improved by the treatment, despite the fact that a careful record of his original state and of the condition at the close of the treatment may show no changes in objective signs and no improvement in visual responses.

A SOCIALIST MEDICAL CONFERENCE

During the last week-end of May a Socialist medical conference was held in Carlsbad, Czechoslovakia. Nearly two hundred doctors were gathered together from different parts of Europe as representatives of some ten national Socialist medical associations. The British section consisted of Mr. Somerville Hastings, M.P., and Dr. W. Rutherford, both of London. They were representatives of one of the smaller sections, because the British Socialist Medical Association has only been in existence a few months, and numbers not more than a hundred members. The German and Austrian sections, however, are much larger; each has over a thousand members, and publishes a monthly paper. The chief business of the conference was the formation of an international association, and the drawing up of its constitution. Affiliation to this will in no way affect the policy or organization of a national section. The central bureau of the association is, for the present, located in Berlin, with Dr. Ewald Fabian as secretary. An executive consisting of one or two members from each of the ten countries represented was formed, and instructed to work out the constitution in further detail, and determine the place of meeting and agenda for the next annual conference. London was one of the places proposed. Perhaps the most elegant speech of the conference was made by Engelbert Graf, Member of the German Reichstag, who dealt with the effects of the present economic world crisis on the public health. It was pointed out that in many countries the health of the children, especially those of unemployed men, was being definitely lowered, and that in the younger unemployed men nervous disorder and crime were increasing. A resolution was carried in favour of larger allowances for the unemployed, raising the school-leaving age to 16, shorter hours of labour, and the building of more houses for the people. The resolution concluded with a declaration that crises like the present will only be permanently abolished when the economic order of society becomes socialistic.

THE ROSS INSTITUTE

The annual report for 1930 of the Ross Institute and Hospital for Tropical Diseases is of special interest in view of the considerable attention paid in it to malaria, particular reference being made to the economic damage done by this disease, and the preventive policy which is advocated by the Ross Institute. Sir Malcolm Watson has prepared a memorandum covering the past history of the fight against malaria and defining the present position; this is published as an appendix to the report. The progress of the antimalarial campaign in the Federated Malay States is discussed in detail, and the value of expending money and thought on health measures is clearly indicated. An Indian branch of the Ross Institute came into active being last August; it is designed to assist industries in the prevention of malaria among their staff and to conduct further researches in this respect. Dr. G. C. Ramsay, who is in charge of the branch, has been making a careful investigation of the malaria problem in Assam. An illustrated booklet has been published in this connexion, showing how a successful biological control of mosquito multiplication can be obtained by planting swamps and slow-running streams with certain plants which grow quickly and completely shut off the sunlight from the water.

THE HISTORY OF THE ASSOCIATION AND THE CENTENARY

In an annotation published in our issue of November 17th, 1928 (p. 905) we gave notice that on the occasion of the centennial meeting next year it was proposed to publish in volume form a *History of the British Medical Association*. For this purpose information as to the foundation of Branches was particularly desired, such as is not accessible in the medical journals, for it was felt that in the minute-books of the older Branches and the records of local medical societies there might be much of interest to us to-day. Any information in any way bearing on the history of the Provincial Medical and Surgical Association or the British Medical Association will be thankfully acknowledged by the Medical Secretary.

THE ST. CYRES LECTURE

We much regret that by inadvertence Sir Thomas Lewis was not sent a proof of the full report of his St. Cyres Lecture which appeared in our issue of May 30th, page 941, under the heading "Ischaemia of Muscle as a Cause of Anginal Pain." Through that oversight Sir Thomas Lewis had no opportunity of correcting a number of mistakes; and he must therefore not be held responsible for the abstract of his lecture as published in these columns.

Mr. N. Bishop Harman has been elected an honorary member of the International Association for Prevention of Blindness, in recognition of his initiation of the myope (or sight-saving) classes for children in London in 1908.

We regret to announce the death, on June 6th, of Colonel Sir Robert H. Firth, K.B.E., C.B., F.R.C.S., late A.M.S.

THE PLACE OF MEDICAL SOCIETIES IN THE PROGRESS OF MEDICINE*

BY

RAYMOND CRAWFURD, M.D.OXON., F.R.C.P.

We are gathered here to-day to celebrate the centenary of the Harveian Society of London, and we are honoured by the presence of representatives of the sister society of Edinburgh, founded in 1782, and of that of New York, founded in 1905. The occasion may be not inopportune for considering some features of the life-history of medical societies in Great Britain.

THE THREE HARVEIAN SOCIETIES

Human activity, in so far as it is enduringly fertile, is not the chance product of a few creative minds, but is conditioned by its antecedents and environment, and tends to express the dominant tendencies of the time. Thus the Harveian Society of Edinburgh was born of a demand that found expression in various ways in the last quarter of the eighteenth century for the democratization of medical knowledge. Phoenix-like it arose out of the ashes of an older Aesculapian Society, membership of which had been exclusive and limited to Fellows of the Royal Colleges of Physicians and Surgeons. The Harveian Society opened wide its doors, not only to these Fellows, but also to medical graduates, neighbouring practitioners, and the naval and military medical services as well. The Scottish genius for conviviality seems to have asserted itself in the constitution of this society, as it kept in the forefront of its programme the cherishing of friendliness among members of the profession, and the degrees conferred by it included "Doctor of Mirth and Social Joy" and "Doctor of Merriment." So this society was true to Harvey's injunction as to the importance of cherishing actively the spirit of good-fellowship as an assurance of usefulness and stability.

The Harveian Society of London was launched on its career of enduring prosperity at a time when educational reform was alive and active in every branch of intellectual activity. In London, in little more than a decade, University College, King's College, and the University of London came into being. Medical societies had already spread from their first metropolitan homes in Edinburgh and London to the provinces, and in 1819 a further tendency to decentralization within the growing metropolis had declared itself in the foundation of the Hunterian Society, for the benefit of the medical profession in the East End of London. The purpose of this Harveian Society at its birth was to do the same for the West of London, for it should be remembered that in 1831 the centre of medical activity was not, as now, in Harley Street, but in the district adjacent to the British Museum.

One important function of medical societies has been to provide a medium for the conveyance of fresh knowledge from the centre to the periphery of the profession. Scientific discoveries tend to be minted in minds concentrated at the centre, but it is by the minds of the multitude of practitioners scattered throughout the country that the golden coins gain extensive currency. The flow of fresh knowledge has thus been mainly centrifugal, and very little in the reverse direction, for the country practitioner is more directly concerned with the art of medicine, which is individual and incommunicable, while the science of medicine is catholic and susceptible of ready transmission. A notable exception, however, to the general rule was Jenner's work on vaccination, a piece of scientific work that was readily practicable only in the milieu of a rural practice; while, later still, from the genius of Manson, Ross, and others, we at home have learned that the highest scientific achievements may be compassed in the outposts of our far-flung Empire. At its foundation this society declared its purpose to be "to promote a free communication and, whenever practicable, a demonstration of facts and inferences relating to all departments of medicine, regarded both as a science and an art." Here, then, was a common meeting ground for the exponents of both the art and the science of medicine, and this throughout its hundred years of existence has been its peculiar cachet.

The Harveian Society of New York was founded in 1905. Its avowed purpose was to convey to the medical profession generally, by means of lectures delivered by experts in different branches of medical science, knowledge gained by experimental investigation in the laboratory. It was felt that such knowledge was liable to be buried in specialized publications that were not readily accessible to the general practitioner. Anyone who is familiar with the annual volumes in which these lectures are published cannot fail to recognize the great measure of success that has attended this high endeavour. This society, then, is the natural corollary of the rapid growth of experimental research that has been an outstanding feature of twentieth-century medicine.

FUNCTIONS OF MEDICAL SOCIETIES

This brief outline of the activities of these three Harveian Societies affords some indication of the various ways in which medical societies have aided in the diffusion of knowledge by the agency of discussions, papers, lectures, exhibition of patients and specimens, demonstrations, and the printing of proceedings, but it does not cover the whole ground, for some societies have enlarged the scope of their transactions so as to include reviews of books and abstracts of articles of scientific value, the usefulness of which to medical men can hardly be overrated, while others have added the manifold amenities of a well-organized library.

The *diffusion* of knowledge has been the primary, but by no means the exclusive, purpose of medical societies, for the methods adopted for the active diffusion of knowledge cannot fail to have some share both in the *acquisition* of existing knowledge and in the *creation* of new knowledge: the larger and more affluent medical societies have indeed lent themselves to the acquisition of knowledge only in a less degree to its diffusion. In the acquisition of knowledge books and periodicals necessarily play an important part, and to this end not a few societies have provided their members with libraries, the most highly systematized of which have already attained a very high degree of utility and excellence.

The creation of new knowledge can in the nature of things form only a very limited part of the activities of a medical society as such. It is true that the intercourse of fertile minds does give birth to new conceptions, and these in turn engender others, and this constitutes a creative act; but the experimenter who would commune with nature must needs enter his chamber and be still, and his chamber is the laboratory, not the meeting house. So, too, fruitful observation postulates the presence of the objects to be observed in a suitable milieu, and in the case of morbid material, living or dead, that milieu is the hospital or its clinical equivalent.

If we trace back the development of medical societies to its source, we find that the earliest were concerned at

* An address to the Harveian Society of London at its Centenary Celebration on June 11th, 1931, at St. Bartholomew's Hospital.

least as much with the acquisition and creation as with the diffusion of medical knowledge: the more restricted function has been gradually evolved. Both Bacon and Harvey have left us a picture of the constitution and scope of the society to which they would have entrusted the future of medical science. Each of these men was a typical product of the spirit of an age that had its roots in the Reformation; each was a champion of the scientific scepticism that, with the emancipation of the human mind from the tyranny of authority and dogma, sought by means of observation and experiment to find a rational basis for the interpretation of physical phenomena.

BACON'S HOUSE OF SALOMON

Bacon believed that science might be immensely advanced if the whole civilized world could be linked up into one scientific federation for the creation and dissemination of knowledge, and his allegorical picture of Salomon's House in the ideal commonwealth of Bensalem represents the organization by which he would make his idea effective. His college was to consist of thirty-six Fellows, half of whom were to be engaged in the acquisition and recording of all existing knowledge of discoveries and inventions from every conceivable source in all parts of the world; the other half, in six groups of three each, was to be engaged in the devising, directing, executing, and recording of new experiments. Such was to be the guiding personnel of his visionary College, of which the equipment was to be on the most lavish scale. If to-day some master mind were to fashion a scheme by which all scientific societies, covering every branch of science, should be amalgamated into one colossal institute, if he were to give each professor a free hand to construct, equip, and staff his department on the most lavish scale the professorial mind could conceive, with the addition of an unlimited secretariat and foreign correspondency, the whole directed by an all-wise and all-embracing research council, we should still have but a pale exemplar of *Bacon's House of Salomon*.

It might appear that Salomon's House has but a slender claim to figure in the lineage of the medical society of to-day, but such is not the case, for there is indisputable evidence that it had a direct and important influence in promoting the foundation of the Royal Society, and further evidence that the earliest purely medical societies did consciously adopt as their model certain features that had been tried and approved in the constitution and procedure of the Royal Society. Bacon did not even differentiate medical science from the general corpus of natural philosophy; nevertheless he did include it, and made abundant provision for the acquisition and creation of new knowledge, while leaving the discoveries to be their own advertisement. Though Bacon, and not Harvey, *is thus the true progenitor of our Royal Society*, that great corporation has flourished not in the leading-strings of Bacon, but by the free and independent pursuit of the method and practice of Harvey. That its birth was delayed until Bacon had been dead thirty-six years and Harvey was in his grave, was again an accident of the times, brought about by the disintegrating influence of years of civil commotion.

Other influences than Bacon's large-scale plan contributed to the foundation of the Royal Society. Evelyn was one of its founders, and his letter to Boyle in 1659, indicating his willingness to endow at his own expense a college, the members of which "would resign themselves to live profitably and sweetly together after the manner of the Carthusian Convent in Paris," shows that the example of the monasteries survived their demolition: his college was to do for science what the monasteries had done for religion.

HARVEY'S CONTRIBUTION TO THE DEVELOPMENT OF MEDICAL SOCIETIES

Due recognition has not been accorded to Harvey's place in the life-history of the medical society, though it is plain for all to see in the indenture by which he conveyed to the College of Physicians his patrimonial estate of Burmarsh. Harvey was not the man to weave from his imagination the insubstantial fabric of a dream, as Bacon had done; he sought to build on foundations that lay ready to receive his superstructure in his beloved College of Physicians; in his mind, as in Bacon's, the organization of the medical society had not emerged from the collegiate stage. In this indenture, after providing for an annual feast within the College, he ends with an exhortation "to search and study out the secrets of Nature by way of experiment; and also for the honour of the profession to continue in mutual love and affection among themselves, ever remembering that *Concordiâ res parvae crescunt, discordiâ magnae dilabuntur.*" In these words Harvey lays down the very lines on which medical societies have subsequently developed, their educational purpose being supplemented by a bond of good-fellowship and conviviality. Harvey had only too good reason to appreciate the value of mutual friendliness to the advancement of medical knowledge. The acerbity and antagonism with which many of his professional brethren had greeted his proof of the circulation of the blood had seared the inmost recesses of his soul, and he is recorded as saying that *the stoniest soil of all was in the minds of men over* 40 years of age. He, too, had reason to stress the importance of the social bond. All his life he had been a solitary worker, tireless, as John Hunter after him, in the practical study of comparative anatomy. Only once do we catch a glimpse of him in active collaboration with a fellow worker, comparing notes of his embryological studies with George Bathurst of Trinity College, Oxford, who kept a sitting hen in his rooms to incubate eggs, which he examined day by day to observe the stages of development of the embryonic chick. That Nathaniel Highmore was also independently at work at the same inquiry in the same College need not lead us to assume that the College eggs were peculiar in suggesting compellingly the study of embryology, but rather, as John Hunter has naïvely said of the development of birds in eggs, "It would almost appear that this mode of propagation was intended for investigation."

One more feature of many medical societies is forestalled in Harvey's will, devising a sum of money for a librarian and for the upkeep of the library he had already presented to the College, so that medical men might have ready access to the contributions that others had already made to the sum of medical knowledge; and for the diffusion of knowledge, were there not in existence endowed lectures, in which he himself had already achieved immortality by first setting forth in his Lumleian Lectures his proofs of the circulation of the blood? Viewed, then, as a whole there is little in the constitution of the medical societies of to-day on which Harvey has not long since pronounced substantial benediction. Perhaps, therefore, our three societies have done well to adopt his patronymic, for the circulation of medical knowledge is as vital to the higher professional life as is the circulation of the blood to higher animal life.

The contrast of Bacon and Harvey is well expressed in some lines of Browning in "A Grammarian's Funeral":

> The low man seeks a little thing to do,
> Sees it and does it;
> This high man, with a great thing to pursue,
> Dies ere he knows it.
> That low man goes on adding one to one,
> His hundred's soon hit:
> This high man aiming at a million
> Misses an unit.

GROWTH OF THE ROYAL SOCIETY

Time does not permit me to retell the familiar story of the growth of the Royal Society out of the union of those two groups of gifted amateurs known as the Invisible College of Boyle and the Philosophical Society of Oxford, or to insist on their indebtedness to the pioneer effort of Sir Thomas Gresham in the foundation of his College in 1575. The transition from a group to a society is something more than the passage from a coterie without a name to a coterie with a name: it is the first step towards the transference of an exclusive possession of the few to the participation of the many. The history of British Medicine is punctuated with informal groupings of fellow workers, such as those of William Gilbert, Glisson, and Erasmus Darwin, for the tendency to cohere is an instinct of the human herd. Such groupings become a society in name when they adopt a formal constitution, but they do not become a society in spirit until the evangelist spirit animates and inspires them to propagate knowledge beyond the narrow confines of their own community or to enlarge the confines by an extension of membership. This evangelist spirit was dominant in the early years of the Royal Society, side by side with its primary purpose of stimulating the creation of new discoveries. At first the work of the meetings consisted mainly in the exhibition of experiments by members and the reproduction of experiments already made by other scientific workers, together with the reading of papers. Besides discussion of experiments shown, a feature was the devising of fresh experiments to be carried out elsewhere. Great pains were bestowed on keeping in touch with work in other countries by an organized system of correspondence with foreign scientific workers, whose letters were duly communicated to the society. Abstracts of important articles in foreign journals were made and read, so that the purview of the society was international. Further, the society took care, by the publication of transactions, to communicate its own work to other countries, as the French *Journal des Scavans* had begun to do for Colbert's scientific coterie three months previously; and in taking upon itself the publication of treatises the society was willing to assume the paternity of Newton's *Principia*. Medicine, or rather the embryo sciences out of which medical science was to arise, received generous treatment at the hands of the society, for two of its eight constituent committees, the anatomical and the chemical, were entirely in the hands of physicians, who enjoyed there facilities not to be found in the College of Physicians.

So the Royal Society led the way in Great Britain in promoting the exchange of views among its members by means of discussion and in the publication of transactions which, both in what they received and in what they gave, looked beyond the narrow confines of their own country, and both these features have figured in many of their descendant medical societies.

THE FIRST MEDICAL SOCIETIES IN EDINBURGH AND LONDON

So far as corporate action for the progress of medicine went, the Royal Society and the Royal College of Physicians held the field until 1731. In that year there came into existence in Edinburgh the first exclusively medical society in the modern sense. The preface to the first volume of its *Transactions* leaves no doubt as to the reasons for its foundation, for these are explicitly stated to have been that the constitution of the Royal Society did not allow it to insert in its *Transactions* several things that a plan calculated for the improvement of physic would easily admit, and, further, the belief is expressed that a collection of observations wholly relative to medicine would be the most effectual way of improving physic. It was not that medicine had been found to be a bad stable companion, but only that she could go better in single harness. The change was momentous, for it involved not only the segregation of medicine from the general body of science, but the handing over of its future to those who were not primarily concerned with scientific research; and the consequence of this was inevitable, that the diffusion of knowledge, and not its creation, became the prime purpose of medical societies. That Scotland should have led the way in the development of the modern medical society is due to the fact that it was the first—inspired by the example of the Dutch—to organize, in 1725, a medical school of practical clinical teaching, and the founders of this society were those teachers of the school who desired that their voices should be heard beyond the four walls of the Edinburgh School of Medicine. The sole purpose of this society was the publication of medical papers, and there was no provision for reading or discussing them before the society.

In 1752 London followed suit in constituting its first medical society, and here again we must admit direct Scottish influence, for Fothergill, its founder, though a Yorkshireman, had received his academic training in medicine in Edinburgh, and had been a member of its second medical society. The London society limited itself to the publication of papers, and like its Scottish prototype rested on a narrow basis of membership of a few hospital physicians and surgeons. Each society was short-lived in its original form, for the Scottish society, by reversing the process of evolution, became first the Philosophical Society of Edinburgh by the inclusion of philosophy and literature, and later, in 1783, the Royal Society of Edinburgh. In this very same year the English society died a natural death, that not even the quickening influence of an annual banquet could stave off, for it had not been granted the faculty of making the dry bones of medicine live, without the vivifying guidance of Fothergill and William Hunter, who had been its mainstays. Maybe, too, its proclaimed purpose of excluding "whatever has rather a tendency to display the parts and erudition of the writer than to advance medical knowledge," led to a dearth of papers. This society, by its example, stimulated a group of Fellows of the College of Physicians in 1767, under the leadership of Heberden, to meet and read papers, which they issued in the form of *Medical Transactions*; but this effort to project the College along the lines laid down for it by Harvey flickered out with the publication of the last volume in 1820. One admirable suggestion in the preface to the first volume may still be practised with advantage: "It is to be wished," says the author, "that writers would not confine themselves to relate only their successful practice. A physician of great experience might write a very useful paper, if he would have the courage to give an account of such methods of cure only as he had found to be ineffectual or hurtful." This hushing up of mistakes and failures unhappily extends beyond writers, and is an almost universal feature of hospital teaching, to the very great impediment of the growth of clinical knowledge.

THE ROYAL MEDICAL SOCIETY OF EDINBURGH

In tracing the expansion of the functions of medical societies, we must again look north to Edinburgh, where in 1734 a few students had banded themselves together for mutual assistance in their studies; Fothergill joined them in 1735. By 1737 they had formally organized themselves into a society, which, growing from strength to strength, built itself a hall, and in 1778 became the Royal Medical Society of Edinburgh. This society marked a definite advance on its predecessor, for it had formal meetings, at which papers were read and discussed, but it

maintained at first the tradition of exclusive membership. Being at the outset a students' medical society, it gives Scotland the claim to have anticipated by many years the formation of the first students' society in London, the Physical Society of Guy's; that was not born till 1771.

THE MEDICAL SOCIETY OF LONDON

For the first far-reaching democratization of medical societies we must look to the foundation of the Medical Society of London by Lettsom in 1773. To Lettsom is due the credit of giving actuality to an idea, but beyond all question the society was the natural product of the professional circumstances of the time. Both Fothergill and Lettsom were licentiates of the Royal College of Physicians, and each had winced under the stigma of exclusion from the Fellowship, which was the virtual monopoly of Oxford and Cambridge graduates who were members of the Church of England. Fothergill had taken an active part in the struggle that was fought out between the College and its licentiates, not only in the law courts, but with a show of violence on the floor of the College itself. Now Lettsom sought to sap the very foundations of the citadel of exclusivenesss by setting up beside it a rival institution, as similar as he could make it in constitution, and as dissimilar in its professional spirit. One cannot fail to see, in its president, treasurer, registrar, librarian, council, library, and museum; in the language and ceremonial mode of admission of Fellows; in the annual oration, and much else, where Lettsom looked for his model. From the beginning this society possessed a meeting house furnished with a library, which Lettsom enriched greatly at his death. But there the resemblance ended, for Lettsom saw to it from the first that his society was broad-based on the enfranchisement of general practitioners on the same footing as physicians and surgeons. Lettsom's foundation seems to have served his purpose, for in 1782 a scheme was mooted for the foundation of a rival College of Physicians, to which the Royal College responded two years later by relaxing so far as to admit two rebel licentiates to its Fellowship.

THE MEDICAL AND CHIRURGICAL SOCIETY

With this democratic society in the field, it may be a matter of surprise that the Medical and Chirurgical Society should have come into existence in 1805. It is commonly alleged that this society was founded owing to dissatisfaction with the protracted presidency of James Sims over the Medical Society. I find it hard to believe that our robust ancestors of one hundred and thirty years ago were unequal to the task of unseating a senile president, and I find a far more convincing explanation in the professional circumstances of the time. The fact was that a young cuckoo had been hatched and had already become too large for the parent nest—namely, modern scientific surgery, brought to birth by John Hunter. The very change of name from "Medical" to "Medical and Chirurgical" tells its own tale, and the chief figure of the surgery of the day, Sir Astley Cooper, figures prominently among the seceders. A ripple had already appeared on the surface of the water in 1783, when John Hunter had established "A Society for the Improvement of Medical and Chirurgical Knowledge," the membership of which never exceeded twelve. Such an exclusive body was bound to go under in competition with its new democratic rival, and it died of inanition in 1818. Moreover, we must not forget that the Royal College of Surgeons had come into being five years previously, in 1800.

So if the birth of the first medical society in 1731 marks the severance of medicine from natural philosophy, and the birth of the Medical Society in 1773 marks the full democratization of medical societies, we may recognize in the birth of the Medical and Chirurgical Society in 1805 the emancipation of surgery from the mortmain of medicine.

MEDICAL SOCIETIES IN THE PROVINCES

Meantime another notable advance had been taking place in the spread of societies from their metropolitan homes to the provinces. Warrington had a medical society as early as 1770, but no provincial society of that century was so famous as the Gloucestershire Society, founded by Edward Jenner in 1788. The minute books of the Gloucestershire Society, in the handwriting of Jenner, are a treasured possession of the Royal College of Physicians, bequeathed to them by Sir William Osler, than whom no one in the whole history of medical societies did more to cement the social bond, by the charm of his personality, the catholicity of his friendship, and the inspiration of his enthusiasm as a crusader. In these manuscript pages may be found a living picture of a rural medical society of the day, but time forbids me to do more than reveal one gem from this treasure house. Rule XIII reads:

> "That as a principal part of the view of the Society is the mutual communication of knowledge, without fear, reserve or any other authority than that of Truth, no new member shall be admitted for these seven years to come whose age exceeds 40 years."

EVOLUTION OF MEDICAL SOCIETIES IN THE NINETEENTH CENTURY

I could have wished for time in which to unravel the tangled skein of fission and fusion by which the Medical and Chirurgical Society has become transformed into the Royal Society of Medicine, for therein lies a typical record of the evolution of medical societies in the nineteenth century; I must restrict myself to a few outstanding features. The first quarter of the century, indeed almost the first half, was a period of static equilibrium, for surgery had now come into its own, and was intent more on its own internal development than on its external relations; the process of decentralization within the metropolis, which gave birth to the Harveian Society, showed, however, that animation was only in suspense. In the second half of the century we find the growth of medicine and surgery asserting itself in an orgy of fission, out of which arose a succession of specialized societies, each engaged in the pursuit of its own limited ideal: the Medico-Psychological Association seems to have struck the first note in England in 1841. But though fission was the dominant note, fusion never passed entirely out of sight. Time and again we find overtures for reunion of the Medical with the Royal Medical and Chirurgical Society, and efforts of young seceders to re-establish relations with the parent body; it remained, however, for the twentieth century to reconcile these antagonistic tendencies by a comprehensive scheme of federation. Of these specialist secessions, two are of particular interest. In 1846 the Pathological Society gave expression by its foundation to the feeling that existing societies paid inadequate attention to pathological subjects. It was indeed the case that until its foundation, in a period when the intensive study of morbid anatomy had become a central feature of medicine, provision for the exhibition of morbid specimens existed only in name; and in 1850, when the Pathological Society was seeking shelter beneath the roof it had recently deserted, the reply of the council of the parent society was that the exhibition of many recent specimens would probably create a nuisance.

So again, in 1867, the Clinical Society came into being as a result of the belief that the parent society cultivated too little the practical aspects of medicine and surgery, but expected its members to extract nutriment from a dry diet of papers. Yet this young society was content for a decade to talk about cases instead of exhibiting them, and it was not till 1879 that it formulated regulations for the exhibition of living cases, and these seem to have borne no fruit until 1882. A lesson might have been learned from the Medical Society, which was showing cases at its meetings as early as 1861.

CONTRIBUTION OF MEDICAL SOCIETIES TO MEDICAL KNOWLEDGE

In the contribution of medical societies to the advancement of medical knowledge we must look for no harvest of great discoveries; their function is rather to afford a meeting place for the mutual exchange of everyday ideas. They do afford the opportunity of advancing or of receiving new ideas, of submitting them to criticism and correction, and of purging thereby the dross from the ore, and in this intercourse of fertile minds new conceptions will certainly be engendered. They do provide facilities for intercommunication to every type of practitioner, and one lesson of Jenner's life seems to be that even in the isolation of a country practice, amid the hourly demands of a toilsome calling, it is possible, with the aid of societies and interchange of ideas with those more fortunately situated, as John Hunter was, to keep the mind alive to every new source of information, and even to carry out original investigations in many branches of medicine, biology, and natural history. The modern development of libraries has brought wide facilities at a trifling cost to every practitioner's door, and, along with the medical journals, has rendered easy communion with the great minds of the present as well as of the past, both in this country and beyond the sea. Societies, too, have been important agents in promoting among medical men that feeling of good-fellowship that is essential for fruitful co-operation; men's minds are massaged by rubbing against each other, and they rub off their angles by mutual attrition. In this, conviviality has played its part, however humiliating it may be to reflect that the tiger in man needs ever to be appeased by the prospect or retrospect of a meal. La Rochefoucauld has said that nothing is so bad as we imagine it to be, and he might well have added "nobody." Few of us but are aware of some personal prejudice, founded on no better grounds than gossip or misunderstanding, melting like snow in the warmth of personal intercourse.

DANGER OF STAGNATION

Anyone who studies the domestic history of medical societies cannot fail to be struck with one circumstance. Time and again a new need has arisen, but the dead hand of inertia has prevailed, and no step is taken to meet the new need; then fission takes place, and a fresh society emerges—often out of the very vitals of the parent society and to its detriment. Why is it that societies tend to lose responsiveness to their environment? Is it that their official administration has in the past been far too much in the hands of the older members? Were Harvey and Jenner and Osler right in believing that 40 years is apt to be quite as critical an age in the lives of men as it is alleged to be in women's valuation of *their* lives? If so, would it not be well that every society should have a regulation that at least one-half of its governing body should be under 40 years of age? That is a question to which I leave each one to make his own answer.

MEDICAL EXAMINATION OF IMMIGRANTS TO CANADA

We have received from Dr. J. D. Pagé, Chief of the Immigration Medical Service of Canada, advance copies of the following paragraphs, which his Department proposes to include in its *Instructions to Medical Officers*. They are addressed particularly to medical practitioners in the British Isles, who, under a roster scheme, examine prospective Canada-bound emigrants.

INFORMATION FOR ROSTER DOCTORS

With a few exceptions, medical examination of immigrants to Canada prior to embarkation was made compulsory in February, 1928. The term "immigrant" includes all persons who are travelling to Canada to settle there, regardless of the class of travel. Transmigrants, bona fide tourists, visitors for business or pleasure, Canadian residents or citizens by birth or domicile, *do not* require medical examination. This examination is primarily to advise the Department of Immigration as to the physical and mental fitness of the applicant, and, secondarily, to protect the interests of the intending immigrant as well as to protect the travelling public and the new community.

In enlisting the services of the local medical practitioner in the examination of prospective British immigrants to Canada, the Canadian Government feels that the Dominion's interests will be served best when the British examiner best serves the interests of his patient, who in this instance will also be the prospective migrant. Years of experience and observation have convinced medical officers of the Canadian Department of National Health that it is altogether unfair and unkind to precipitate into either the general labour market or the pioneering life of this new country individuals from the comparatively sheltered life in the British Isles who are constitutionally below a high average with regard to either physical or mental reserve power.

Perhaps not greatly in any one instance, but certainly in the sum total, such conditions as indicated below constitute serious difficulties for all newcomers during their first few months in Canada, and in some cases prove to be insurmountable—for example, marked change in climate, including, by comparison, extremes in temperature, excessive amount of sunshine, high altitude, thin, dry atmosphere, all of which are trying on the nervous system. Comparative isolation in outlying districts, change in money standard, food, cooking, and dwellings. Complete change in local interests and details regarding social life and activities. Considerable difference in customs and routine methods of doing work and business generally, all tending to a period of home-sickness of such severity as to be really disabling.

Disappointment may arise, too, from the erroneous idea that less work will produce a better living in the new country, when as a matter of fact Canada offers better returns only in exchange for more, and often harder, work than is available in the Mother Country. Moreover, the release from the restrictions of a crowded community afford an apparent freedom, and the release from the restraining influences of the home environment is often too much for those persons lacking in self-control or moral responsibility.

It is of particular importance, therefore, in examining prospective emigrants to detect not only the obvious physical or mental defective, but also those cases on the borderline between sanity and insanity—individuals who possess defective judgement, instability of the nervous system, or who are emotionally hypersensitive; also those who at some time previous have been insane. As well, too, those who suffer from epilepsy, latent syphilis, chronic or recurrent conditions such as tuberculosis, rheumatism, bronchitis, renal, gastric, or arterial disease, skin diseases producing either disability or loathsome appearance.

Certain of the conditions mentioned may produce very few signs or symptoms, and fail to attract attention while

the individual is living a normal routine life in his native environment. Too often, however, these conditions prove to be the undoing of the new settler when subjected to the stress and strain of accommodating himself to an entirely different environment.

On account of the sparsity of Canada's population compared to her vast area, and the tremendous cost *per capita* of developing and maintaining public utilities and institutions, the immigration laws have provided for the rejection, at port of landing, of physically or mentally defective persons seeking admission to the country, or, if landed, the deportation to his native land of any immigrant who before qualifying for full citizenship becomes a charge upon public funds. The position of such a deportee upon returning to his homeland is usually far less satisfactory than before going abroad, for in all probability he will have no immediate employment and no home, and his physical, mental, and financial resources will be lessened, to say the least. Much of such hardship is preventable by means of careful and conscientious medical examination of prospective migrants before giving up their employment or disposing of their homes.

The Canadian Government feels that a close and friendly co-operation between the British medical man making the actual examination of British subjects and the Canadian medical officer specially trained in immigration medical work, will, on the one hand, mitigate suffering and hardship on the part of the immigrant, so far as is humanly possible ; and, on the other hand, relieve the financial burden on Canadian public funds resulting from the physical or mental collapse of new settlers. In such co-operative scheme the British practitioner's responsibility is purely medical ; that is, a careful examination of the prospective emigrant's physical and mental condition, together with an investigation of his medical history ; the submission of a report of the medical examiner's findings, with an expression of opinion as to diagnosis and prognosis regarding any abnormalities noted, having in mind that the patient is planning to migrate to a new country. With such a pen picture of the patient as above indicated before him, the Canadian medical officer, with his knowledge of Canadian conditions and special training in immigration work, would be in a position to express a reliable and intelligent opinion, from a medical viewpoint, as to the advisability of the applicant's migration to Canada.

ROYAL MEDICAL BENEVOLENT FUND

At a recent meeting of the committee of the Royal Medical Benevolent Fund, fifty-nine grants were made, amounting to £1,341. The following are particulars of a few of the cases helped.

Dr. X, aged 65, married. At the special request of the honorary secretary of the local British Medical Association Division, an emergency grant of £10 was given, also an annual grant of £40, payable in four instalments. Owing to being crippled with rheumatism, the applicant has been unable to carry out his professional duties, and he and his wife were known to be nearly destitute, and suffering from lack of food.

Widow, aged 78, of M.R.C.S. When her husband died in 1911 the widow went to live with her only son, who had a dental practice. When the son married ten years ago his mother continued to live with him, as she had no home of her own nor the means to support one. The son died three weeks ago, and the applicant was absolutely stranded ; the furniture and little else went to his widow. The applicant suffers much from chronic asthma, and at her age it is impossible for her to follow any remunerative occupation. A month ago the applicant was living comfortably with her son and daughter-in-law, enjoying the ordinary benefits of home life ; now she has to face the difficult problem of fending for herself on an income of under £50. The Fund voted an annual grant of £26, and is endeavouring to obtain further help from other societies for this very sad case.

Widow, aged 70, of M.R.C.S. The applicant has maintained herself since 1899 by working as a companion-housekeeper. Her employer died in August, 1930. She is now too old to obtain other employment, and her income consists of the old age pension of £26 and a grant of £25 from the Indigent Gentlewomen's Society, making £51. The applicant is an educated and cultured woman, feeling her position very acutely. It was only with a very great deal of persuasion that she would consent to an application being made to the committee. Fund voted £26.

Daughters, aged 76 and 69, of M.R.C.S. These two sisters, who, on the death of their father in 1871, were left comfortably off, now, through the reduction of dividends, were found to be sharing a total income of £89 a year, out of which they have to pay rates of £12. Fund voted annual grant of £20 to each sister.

Dr. Z, aged 75, married. Applicant gave up practice in 1927 to undergo a serious abdominal operation, from which he made a good recovery. Since then he has been doing locumtenent work from time to time. His last employment was for thirteen months, which ended in September, 1930. Since then he has been unable to find work, and has been drawing on his capital, which is now reduced to £45. His wife was trying to find employment, but recently met with an accident, and is in hospital. Fund voted £40.

Subscriptions and donations are very urgently needed in order that the activities of the Fund may be continued and the applicants given the help they need. Cheques should be forwarded to the Honorary Treasurer, Royal Medical Benevolent Fund, 11, Chandos Street, London, W.1.

The Royal Medical Benevolent Fund Guild still receives many applications for clothing, especially for coats and skirts for ladies and girls holding secretarial posts, and suits for working boys. The Guild appeals for second-hand clothes and household articles. The gifts should be sent to the Secretary of the Guild, Tavistock House (North), Tavistock Square, W.C.1.

Scotland

HEALTH OF SCOTLAND

The second annual report of the Department of Health for Scotland,[1] dealing with the year 1930, draws attention to the fact that the period under review was a particularly difficult one, owing to the continuance of unemployment and the great changes introduced in local government. In consequence of the Unemployment Insurance Act, 1930, the number of able-bodied unemployed chargeable to Poor Law authorities was reduced by about 50 per cent. ; the number on May 15th, 1930, being 181,759 (37 per 1,000 of population) compared with 210,956 at the same date in the previous year. Despite extension in the few schemes available for training and work the Department considers that there is urgent need to amend the Scottish Poor Law in order to provide for an alternative to unconditional relief in money. As far as the medical services are concerned, the year has been one of adjustment rather than of development, the local authorities having been occupied largely with problems of organization. Various suggestions are made in the report as to the lines on which future progress of a unified health service might be carried out.

Sanitation and Food Supply

A questionary was issued by the Department in August requesting particulars of water supplies in burghs and districts. The replies indicated that in many districts there was no adequate margin for future extension, while in some areas no provision had been made for filtering water obtained from cultivated land. A Reservoir (Safety Provisions) Act was passed during the year with respect to liability for damage caused by escape of water ; periodical inspections of reservoirs will take place at intervals of not more than ten years. Towards the end of the year the Department received the first report of the Scottish Advisory Committee on the prevention of river pollution, dealing with the River Tweed and its tributaries. The committee recommended the provision of sewage purification works for treating domestic sewage and trade wastes at various towns situated near the river, and the Department is urging the local authorities to take the necessary

[1] Cmd. 3860. Edinburgh: H.M. Stationery Office. (6s. 6d. net.)

action. The committee now proposes to direct its attention to the River Leven (Fife). Last year the Department investigated a complaint regarding mosquitos in the Trossachs district. These were found to be culicine mosquitos, incapable of conveying malaria, but becoming a nuisance in the summer months owing to their large numbers; the Department recommended that the area of their propagation should be drained.

In regard to food supply, attention is drawn to the fact that during 1930 two events gave a great impetus to public interest in the value of milk. One was the passing of the Education (Scotland) Act, 1930, which conferred power on education authorities to supply certified milk to school children, and the other was the investigation into the effect on growth of a daily ration of milk. This experiment was conducted in sixty-seven Lanarkshire schools upon 20,000 children, of whom 10,000 received three-quarters of a pint of Grade A milk for four months, 10,000 acting as controls. The conclusion was reached that no other food product possessed the intrinsic value of milk as a growth factor in nutrition. Improvement is recorded in the condition of town byres, and there is evidence of a continued transfer of milk production to landward areas. The Department decided that if veterinary inspection was to achieve its purpose, three inspections a year in landward areas and four inspections in burghs should be provided by local authorities. The figures obtained from the examination of 264,355 dairy cattle during 1929 showed that 0.35 per cent. were tuberculous, but it is believed that with more frequent inspection, a higher rate of tuberculosis would be disclosed. The report states that the proportion of tuberculous cows endangering the milk supply is slightly over 1 per cent., and urges that an increased demand by the public for tubercle-free milk would help towards the eradication of tuberculosis from dairy herds by producers themselves. There are now sixty-four certified herds and seventy-six Grade A (tuberculin-tested) herds licensed by local authorities under the Milk Order (Scotland), 1930, the number of animals in these herds being about 5,800.

Maternity Service and Child Welfare

The local authorities in Scotland for maternity service and child welfare are now the town and county councils. At the end of 1930 these employed 122 whole-time health visitors and 478 part-time visitors, of whom the greater number were district nurses. The maternal mortality rate in Scotland during 1930 was 7.0 per 1,000 births, of which 2.3 per 1,000 were attributed to puerperal sepsis. These rates have in recent years shown on the whole a tendency to increase. Attention is drawn to the reports issued in 1930 from the health departments of Glasgow and Aberdeen dealing with this subject, and the necessity is emphasized for further investigation as to its causes. During 1929, of the total births in Scotland, about one-half were attended by doctors, one-third by midwives, and one-sixth were supervised in maternity institutions. The proportion of expectant mothers who sought ante-natal advice at clinics amounted in Aberdeen to 40 per cent., in Edinburgh to 50 per cent., and in Glasgow to 60 per cent. The number of practising midwives in Scotland at March 31st, 1931, was approximately 4,900, representing an increase of 150 on the number at the same date in the previous year. The proportion of births attended by midwives has shown a tendency to decrease in recent years—for example, in 1922 midwives attended 37 per cent. of births, while in 1929 the proportion was 33 per cent. The supply of midwives in Scotland is regarded as more than adequate, but the Department is endeavouring by means of grants to ensure a higher standard of skill by encouraging trained nurses to undertake midwifery training. Infant mortality continues to decrease; the number of children under 1 year who died in Scotland represented a mortality rate of 83.0 per 1,000 births—the lowest yet recorded except in 1923, when the rate was 78.9. Reports of medical officers of health for 1929 revealed that in areas where child welfare schemes were in operation, 80 per cent. of the children born during the year were visited by health workers. The number of deaths among children between the ages of 1 and 5 represented a mortality rate of 10 per 1,000, as compared with 11.9 in the preceding year. Of the children in this age group, about a quarter come under health supervision provided by child welfare schemes. This proportion is not regarded as satisfactory, and the Department has emphasized the necessity for an improved service of health supervision for the pre-school child in circulars addressed to local authorities. The suggestions are made that parents should be educated in regard to the need for regular health supervision, that existing services for visitation, maternity, and child welfare centres should be extended, and that the school medical service should provide for medical inspection of pre-school children.

School Health Administration

Prior to the operation of the Local Government (Scotland) Act, 1929, arrangements existed in twenty-two counties whereby the public health and school medical services were co-ordinated, but now, for the first time, school health administration has become part of the general public health administration by local authorities. The medical personnel employed in this service at present includes 36 school medical officers, 67 assistant school medical officers, about 50 part-time local practitioners engaged in inspection and treatment, 44 whole-time and 39 part-time school dentists, 72 part-time specialists for the eye, nose, throat, skin, etc., and 694 nurses, including 176 engaged in whole-time work. The system of medical inspection is based upon a careful and detailed examination of generally three age groups. Children aged 5, 9, and 12 years respectively are examined in the primary schools, also children aged 16 years in the secondary schools. This work entails much more than systematic medical inspection, because it involves, for example, the provision of clothing for necessitous children, and the selection of suitable cases for convalescent and holiday institutions. Parents, it is stated, should be encouraged to attend the medical inspection of their children in the schools. The number of children of the selected age groups medically examined during the year was 263,334, while re-examinations amounted to 82,634, and special examinations to 146,332, making a total of 492,300 out of 741,801 children in average attendance at school. Details are given in the report of the percentages of children found defective in various respects; 2.3 per cent. had anaemia, 9.3 per cent. had enlarged cervical glands, 56.9 per cent. were found with one to four teeth decayed, 14.3 per cent. had enlarged tonsils, 5.4 per cent. bad vision, and the nutrition of 5.9 per cent. was below the average. According to the statistical data for these defects there appears to be a general and steady improvement. The report concludes that provision for the treatment of the common ailments of children is satisfactory in populous areas, but that more extensive arrangements must be made in rural districts, especially for dental treatment. Attention is directed to the special classes or schools for children with ringworm and allied conditions that have been established in Edinburgh and Aberdeen. Further reference to the report will be made in a later issue.

Contributory System for Voluntary Hospitals

An address on the future of voluntary hospitals was delivered by Sir Robert Bolam on May 29th in the City Chambers, Edinburgh, under the presidency of Lord Provost Whitson. Sir Robert indicated that the voluntary

hospitals had now come to serve about 80 per cent. of the community belonging to the working class, but that only about 4 per cent. of their patients belonged to the Poor Law class, for which the voluntary hospitals had originally been instituted. While the class of the self-employer in small individual businesses provided some 4 per cent. of their patients, those who in a financial sense constituted the upper and middle classes, amounting to about 12 per cent. of the community, were not provided for by the hospitals. A point had been reached where middle-class people could not command medical treatment outside hospitals which was equal to that provided in hospitals organized on a system of team work with specialists in different departments who could assist one another, and provided with expensive equipment for diagnosis and treatment. On the other hand, hospitals were greatly handicapped at present by the necessity of applying part of the revenue of their capital for current expenditure. He suggested that in the Edinburgh area, with a population of some 1,200,000, there were approximately 400,000 persons insured under the National Health Insurance Act, who, by subscribing 1d. per £ of their weekly wage, could provide some £200,000 yearly to finance the hospitals. Under such a contributory scheme the particular hospital in which a member was treated would be reimbursed for the work done. He instanced the experiment that was being conducted at Newcastle along these lines by which anyone with an income of less than £250 a year could have the benefit of a hospital service at 3 guineas per week. An important point in this connexion was that the medical profession could not afford to go on giving hospital service continuously on the present gratuitous system. The financial recognition need not be much so far as the individual patient was concerned; out of the charge of 3 guineas, 2s. daily was allotted to medical treatment and 7s. daily for the maintenance of the patient in hospital.

Elphinstone Celebration at Aberdeen

A four days' celebration of the five-hundredth anniversary of the birth of Bishop Elphinstone began on June 4th at Aberdeen. William Elphinstone, who was Bishop of Aberdeen and Chancellor of Scotland, founded King's College in the town of Old Aberdeen in the year 1494, the College being completed in 1505. It is noteworthy that one of the teaching staff from the beginning was a mediciner. This was the first university recognition of medicine in Great Britain, the appointment of the mediciner at Aberdeen preceding the appointment of a professor of medicine at Oxford and Cambridge by a generation. The leading part in the ceremonies at the dedication of the monument to Bishop Elphinstone and the opening of the Elphinstone Hall was taken by Lord Meston, Chancellor of the University. The memorial consists of a life-size recumbent figure of Bishop Elphinstone, executed in bronze and placed on a massive base of black marble. In his address Lord Meston gave a historical account of the period in which Bishop Elphinstone lived, and intimated that the cost of the memorial hall had been approximately £35,000.

Glasgow Home for Incurables

The Dowager Duchess of Montrose on May 30th opened a new annexe at the Glasgow Home for Incurables, Broomhill. The new building, which is of three stories, contains a recreation room, a new women's ward, and an electrical treatment room with dressing-rooms and dispensary. Mr. James Macfarlane, LL.D., presided at the opening ceremony, and recalled how the Duchess of Montrose had organized a bazaar in aid of this home during the war, the proceeds of which had amounted to £40,000. After the ceremony, there was an exhibition of handicraft work made by the patients.

England and Wales

London University New Buildings

The Court of the University of London has appointed Mr. Charles Holden, F.R.I.B.A., senior partner of the firm of Messrs. Adams, Holden, and Pearson, to be the architect of the new buildings which the University proposes to erect on its site in Bloomsbury, on the north side of the British Museum. The choice of Mr. Holden has been made after careful deliberation and exhaustive inquiries, and the procedure followed by the Court has included visits to various parts of the country to inspect the outstanding works of architects whose names were to be considered. Mr. Holden has had experience of buildings of a university character, among which may be mentioned the new buildings of King's College of Household and Social Science on Campden Hill. Probably his best-known work of recent years is the new Underground building at St. James's Park, for which he was awarded, by the Royal Institute of British Architects, the London architectural medal for 1929. The Court believes that its appointment of Mr. Holden as the architect of the University's new buildings will meet with the approval both of members of the architectural profession and of the general public. Mr. Holden's task will be a large one. When building operations begin the site will be an island one of over ten acres, bounded on the south by Montague Place, on the west by Malet Street, on the east by Russell Square and Woburn Square, and on the north by Gordon Square and Byng Place. Among the first buildings to be erected will be the Administrative Offices, the University Hall, and the University Library, premises for the Officers' Training Corps, and buildings for the Institute of Historical Research and the Courtauld Institute of Art. To these will in all probability be added the London Day Training College, and the Court's programme provisionally includes accommodation for Birkbeck College, the School of Oriental Studies, and the University Students' Union. Space will also be reserved for other purposes, among which residential accommodation for students, a faculty club, and residential chambers for staff will be considered. This building programme will of necessity have to be undertaken in stages, and will take many years to complete, but, with a view to ensuring that, when the work is ended, all the buildings will form part of a dignified and harmonious scheme, Mr. Holden is being asked to prepare at once a design for the whole of the site.

Cancer Research in Yorkshire

The fifth annual report of the Yorkshire Council of the British Empire Cancer Campaign covers the twelve months ending March 31st, and reveals the contributions made to progress in this respect by that county. Special attention is drawn to the researches conducted at the Universities of Leeds and Sheffield. Professor R. D. Passey, discussing the work done at Leeds by Dr. Young on experimental hyperplasia, mentions that evidence has been obtained that the onset of epithelial hyperplasia conforms to the same principles of physical chemistry as those which regulate the precipitation of negatively charged colloids. Such precipitation would appear to be an essential phase in the sequence of biological changes which culminate in cell division, preceding, indeed, the earliest alteration which can be recognized microscopically—namely, swelling of the cells. Dr. Berenblum has advanced further with his study of the anticarcinogenic action of dichlorodiethyl sulphide (mustard gas). His experiments fail to support the suggestion that mechanical irritation normally plays an important part in the production of tar tumours, and Dr. Bonser, following lines

parallel with those of Dr. Berenblum, has shown that four Scottish blast-furnace tars, and one English tar, possess carcinogenic properties, though not in so high a degree as one would expect to find in ordinary gas tar. The question of heredity is still being investigated, and there seems to be a certain correlation between the date of appearance of warts in parent and offspring. The cancer-producing powers of radium are being tested experimentally, and so far no support has been obtained for the view that radium has growth-promoting properties dissociated from concomitant injuries. At Sheffield Professor E. Mellanby has continued the observation of the metabolic changes of cancerous growth, and especially the lactic acid production, which is generally regarded as indicative of the main energy changes of such tissues. It has been found that phosphatase, unlike diastase, does not influence the lactic acid production of cancer, a fact which is in accordance with the view that phosphates play no part in cancer glycolysis. It has become increasingly clear that the problem of cancer, in so far as it is related to nutrition, is quite different from the problem of many pathological conditions which are influenced by nutritional factors. Certain foods are known which prevent in specific ways the development of hyperplastic changes in growing tissues. These foods do not inhibit the growth of cancer in animals, however, but actually, in many cases, increase the rate of growth when the specific carcinogenic agent is present. So far there is no evidence that suitably selected food will prevent cancerous growths from developing when the specific stimulus is present. Propaganda lectures to medical practitioners, the public, and, for the first time, to nurses, have been given in Yorkshire during the year under review, and literature has been circulated.

Development in Relation to Heredity

The Cavendish Lecture, delivered to the West London Medico-Chirurgical Society at Kensington Town Hall on June 5th by Professor Julian Huxley, was a fascinating discourse on biological problems. Professor Huxley began by pointing out the apparent anomaly that the minute particles, so to speak, which constitute the hereditary outfit and determine the shape of the head, the colour of the eyes, and so forth, were scattered in a mosaic, without relation to one another; while, on the other hand, development was always an extremely orderly process, following a unity of its own. How did the unconnected units of hereditary endowment become translated into an orderly process of development? All recent work, both on fossil forms and on closely allied species or sub-species, said Professor Huxley, showed that while the original conception that evolution consisted of very gradual steps, obeying definite laws, was correct, yet, coincidently with this, there were changes which took place in jumps. All the higher organisms began as a single fertilized egg; and it was now known that in the early stages, with the division of the egg into a number of cells, each one of the cells got the same outfit of chromosomes. How, then, did differentiation occur during development? The explanation appeared to be that the factors which elicited the difference between different regions of the body were, in the first instance, always outside the egg itself. Bilateral symmetry, for example, was determined by an agent outside the egg—namely, the entry of the sperm. An external agency imposed the primary axis of symmetry on the egg, and once this axis of symmetry was imposed there seemed to be a physiological gradient. Professor Huxley, with the aid of lantern slides, illustrated some recent and older work in experimental embryology, such as that in which the immersion of the embryo in slightly toxic solutions had caused the development of monstrosities. One illustration concerned the gills of the salamander larvae, which evidenced a compensatory adjustment to oxygen in the environment; with excess of oxygen the gills shrank almost to nothing, and with deficiency of it they expanded to a very great extent, so as to present as wide a surface to the available oxygen as possible. The stresses and strains to which the organism was subject during development accounted for much differentiation in structure and function. One did not need to ascribe to natural selection or heredity, for example, the adjustment of the tendons to the weight and stress they had to carry. The ductless glands Professor Huxley described as a great labour-saving device from the point of view of heredity, because one quantitative change in one ductless gland could produce a great many complicated changes all over the body. Professor Huxley also discussed different physical types in human beings—the asthenic, the athletic, and so on—in relation to temperament. How unthinkable was Dr. Johnson's physical endowment with the fanatical mentality of Calvin. No one could imagine Don Quixote as fat or Sancho Panza as thin. The lecturer went on to show how differences of proportion were due in the long run to differential growth rates. He instanced the claw of the fiddler crab, which grew at a rate greatly in excess of the body, the enormous jaw of the male stag-beetle, and the antlers of forest deer. Graded effects were represented by the beautiful involuted shell of the nautilus, and the spiral horn of the rhinoceros and other mammals, due entirely to the fact that the rate of growth on one side was different from what it was on the other, otherwise the horn would be a mere cone. It was this graded change which had transformed a creature originally something like an ox into the giraffe. Professor Huxley concluded by saying that the biologist to-day was able to link up different aspects of his subject and to provide food for further thought by those who were studying the development of the finished product in the human organism. Biology hitherto had proceeded in watertight compartments—comparative anatomy, physiology, a study of heredity, and development, and so on—but the time was now coming when these various studies were beginning to be linked up in the same way as the different branches of physical and chemical science began to link up at the end of last century.

Child Guidance

The second report of the children's clinic at "The Quest," 85, Clarendon Road, W.11, indicates the progress made during the twelve months to September 30th, 1930, in restoring to mental and physical health children suffering from neuroses, by enabling them to face their own difficulties and work out within themselves the solution of their conflicts. The first report was referred to in the *Journal* of January 25th, 1930 (p. 167). In spite of inadequate income the work of the clinic grew apace in the second year, and during the last six months there was built up an administrative machinery and a system of recording and analysing the results. A scheme of medico-sociological research is being devised for tracing the causes of neurosis in children. Lack of accommodation has prevented children from being received on more than two afternoons a week; even so, much difficulty has been encountered in providing suitable conditions for the clinical investigations and treatment. The Child Guidance Council has lent one of its social psychiatric workers to help on the social side of the clinic, and a formal training course has now been brought into being. A unified method of handling each case is set out, full scope being allowed for individual differences. The course covers one year of three terms; students are accepted who have already passed some

standard test in any recognized branch of training in medicine, teaching, social work, or welfare work. Practical work in psychology is supervised by the director of the clinic, the cases are summarized, and lectures and demonstrations are provided. The fee is 21 guineas for the year, payable 7 guineas a term in advance. Further particulars of this training course, as well as other information about the clinic, may be obtained from the secretary.

Correspondence

RADIUM: POSSIBLE EFFECT IN PROPHYLAXIS OF CANCER

SIR,—At the present time there are a considerable number of patients treated for small fibroids and menorrhagia at the menopause by means of radium. The radium is generally placed in the cervix and body of the uterus, and it will be of considerable interest to watch these cases and see if they all remain free from malignant disease of the uterus in after-life. It will, of course, require many years, and a great many cases, before any statistics worthy of the name can be collected. I would, however, ask through your columns that all practitioners take careful notes of any of their patients in whom this treatment has been carried out, so that at a later date large statistics may be available. If it should prove a prophylactic for carcinoma of the cervix it will be a very big step forward.—I am, etc.,

London, W.1, June 6th. MALCOLM DONALDSON.

MICROCEPHALY

SIR,—In his letter on microcephaly (*British Medical Journal*, June 6th) and its kindly reference to myself, Dr. Noel H. M. Burke correctly reflects my views on the association of microcephaly with amentia, and points to my departure from the hitherto more usual practice of regarding microcephaly as only one of several types of mental deficiency. The reasons for my conversion are, very briefly, as follows.

I know of no satisfactory methods by which a definite shape of head can be proved to be associated with either amentia or dementia. Circumferential tape measurements and the cephalic index have both been tried and found wanting, and there does not seem to be any satisfactory instrument which will do for the living head what the dioptrograph does for the skull. I am therefore unable to accept previous teaching that microcephaly as one of the types of mental deficiency depends far more on shape than on size.

On the other hand, size of head as recorded in accordance with the recommendations of the Anthropometric Committee of the British Association for the Advancement of Science, from which can be calculated the cubic capacity of brain and the results compared with the now known and well-established percentile figures for both sexes and all ages, is a new departure which gives positive and illuminating results, and even enables us at times to form some notion of the probable state of development of the individual's pyramidal and fusiform cortical cell layers.

In an examination of 1,391 unselected mentally deficient patients from a large Victorian Children's Hospital in Melbourne, I found that 62.2 per cent. were definitely microcephalic, whereas a check experiment on 8,533 normal public and State school children revealed only 19.5 per cent. to be of similar microcephalic dimensions.

Of 131 adult female defectives now under examination at Stoke Park Colony, all over 16 years old, with a mental ratio of not less than seven years and all feeble-minded, 88 cases, or more than 67 per cent., are at definitely microcephalic levels, and of these, 49 are so microcephalic as actually to fall below the zero percentile for their age and sex.

But macrocephaly is also associated with amentia, though to nothing like the same degree as microcephaly; but as it is impossible to enter here into this larger field I may content myself with a sentence from my report on mental deficiency in the State of Victoria (1929), which is confirmed by later experiences amongst English defectives. "This dispersal of the abnormal (mentally defective) cases away from the true means is also shown by the greater readings of the standard deviations, and thus both tables (that is, the mathematical true means and the percentiles) prove once more that the mentally abnormal tend to have abnormal heads, and the generalization is applicable to both sexes."

I have therefore been compelled to the conclusion that there is no particular shape of head associated with mental deficiency. But that two-thirds of all defectives are so small-headed as to be microcephalic, while another 25 per cent. are at abnormal macrocephalic levels, appears to me to be both true and proved.—I am, etc.,

Stoke Park Colony, June 8th. RICHARD J. A. BERRY.

OPERATION FOR CATARACT

SIR,—In your issue of June 6th (p. 1001) Dr. Traquair raises the question whether an operation for cataract in one eye, when the vision of the other is sufficiently good to enable the patient to carry on his work, is advisable or justifiable. In my opinion, when the sight of the cataractous eye is so defective as to be useless for ordinary visual purposes, but in the opinion of the surgeon is operable, the cataract should be removed by operation if the better eye shows that cataractous changes have already begun. My reason for this is that opacification of the lens of the better eye will probably increase, and it is advisable to prepare the more definitely cataractous eye for visual purposes in advance, and not to wait until the patient is reduced to a condition of visual impotency.

The designation of some cataracts as immature is frequently a misnomer. When the opacity is situated in the posterior cortex of the lens, leaving the rest of the lens almost clear, the cataract is often styled immature. Such a cataract interferes very greatly with visual acuity. It may, however, be removed entire by any of the various methods of operation without the slightest difficulty.

The question of driving a car after cataract operation depends not only on the visual acuity obtained with the cataract glasses, but also on the individual psychology of the patient.

Dr. Traquair's third point is: If a patient has had a successful operation performed on one eye, is any material advantage to be gained by operating on the other commensurate with the risks involved? In my opinion, if the cataract in the other eye is operable, there is very great advantage to be gained by successful operation. In most cases the patient regains binocular vision, and, what is of very great importance, restoration of his visual field. Even in cases of monocular cataract resulting from traumatism I am accustomed to advise operation in order to restore, as far as possible, the normal visual field, a matter of great importance to motorists.

There is little doubt in my mind that the most important cause of cataract is the long-continued presence of some form of focal sepsis. The careful search for such a focus, and its elimination, have often, in my hands, delayed the further development of such cataractous changes in the lenses as are likely to interfere with

vision (see *Westminster Hospital Reports*, vol. xx, 1929). The failure to look for possible sources of sepsis, which may be the roots of previously extracted teeth in an edentulous patient, is responsible for many unsuccessful cataract extractions. By carrying out this procedure and employing modern methods of local anaesthesia, the risks of a cataract operation, of which Dr. Traquair speaks, have been greatly diminished during the last few years.—I am, etc.,

London, W.1, June 8th. A. F. MACCALLAN.

SIR,—The letter by Dr. H. M. Traquair in your issue of June 6th in reference to the above is of considerable interest, and I think brings out the point that each case must be decided on its own merits, and that no hard-and-fast rule can be laid down as to the advisability of operation in cases of cataract where there is still useful vision in the other eye.

The patient, of course, generally expects to recover full single binocular vision after removal of the cataract. This, unfortunately, is an impossibility, as one can readily understand from a brief study of the optical principles involved; so that if one does remove a cataract from one eye whilst the other eye has 6/18 vision or more, the patient is then faced with the choice of using either the "sound" eye or the operated eye with a correcting lens. He cannot use both together (if he wears his cataract lens) without getting diplopia, owing to the difference in the size of the retinal images. He will generally, as Dr. Traquair says, prefer to use the unoperated eye even though the other with a correcting lens may have the better vision.

One practical point, of great advantage in these days of fast-moving traffic, which I think should be considered when deciding for or against operation in cases of cataract where there is still useful vision on one side, is that while it cannot restore single binocular vision it does restore the normal field of vision for moving objects—thus enabling the patient to walk with much less risk in traffic.

I think the same point arises when one is considering whether to remove a cataract from the second eye subsequent to a successful operation on the first. If the patient is active and able to walk about, I think his chances of avoiding accident in the street are much increased by removing the second cataract. In this connexion I have heard it stated that there is more risk, other things being equal, in operating on the second eye than on the first, and I would be glad to know if this is a general experience, as it is contrary to my own.—I am, etc.,

Bournemouth, June 6th. DAVID HARDIE.

OBSTETRIC SHOCK

SIR,—The paper on obstetric shock by Professor Miles H. Phillips in the *Journal* of May 16th was so admirable and well reasoned that I hesitated to point out what to me appears a tiny flaw in it—the inconsistency of his opening assumption that "a fatal case of shock following a labour is a rare experience for any individual medical practitioner" with his conclusion as to "the grave danger caused by the use of chloroform." The latter phrase, torn from its context, does not quite represent the meaning of the paper; but if chloroform were as active in the production of shock as Professor Phillips, on theoretical grounds, insists, obstetrical shock would be an occurrence familiar to most of us. In general practice the drug is still widely used.

What leads me into this discussion now is a desire to amplify certain factors which may bear upon the tragedies cited in detail by Professor Phillips (p. 837) and Dr. Peter McEwan (p. 955)—protracted labours, both, in which death took place hours after delivery, with the placenta still *in utero*—emotional shock or pituitrin being blamed or suspected as cause. Dr. F. G. Crookshank (p. 912) emphasizes the psychological aspect which modern obstetrics, for all its preoccupation with the affairs of expectant mothers, tends to ignore. The majority of women are obsessed with the idea that they will die in labour. Women have always felt so, and generally they are silent about it; but their dread cannot nowadays be diminished by the publicity given to facts and figures concerning maternal mortality, the vivid definition of the risks of motherhood. For months they live under sentence; but things reach a crisis in labour; the woman is tortured with apprehension as well as racked with pain. Mental excitement and physical effort exhaust her nerve centres. If labour goes briskly forward she hopes again, but delays make her alert to every look and whisper—and modern obstetrics is, too often, a matter of "masterly inactivity" and looks and whispers. Professor Phillips says that the onset of shock is predisposed to by the use of chloroform "on two or more occasions during a labour—for example, for the induction of labour, or for a thorough examination in the earlier stages, and later on for the actual delivery or for repairs of lacerations"—and his words conjure up the disappointments and protraction of too many modern labours. Even when she awakes from the anaesthetic a woman may be disappointed. Consciousness that the placenta has not come away will engender dread. I am not advocating reckless intervention, but there is such a thing as reckless inaction, and a woman may easily reach exhaustion in efforts, hour after hour, alone or aided only by doses of pituitrin, to accomplish the impossible or the next-to-impossible. When she awakes from the anaesthetic the realization that her task is quite accomplished is one great antidote to obstetrical shock. Another, as Professor Phillips hints, is the support of a firm binder.—I am, etc.,

Belfast, June 1st. ROBERT WATSON.

BLOOD TRANSFUSION AND DAMAGED KIDNEYS

SIR,—I would like to express my appreciation of Dr. Arnold Osman's timely warning against blood transfusion when the kidneys are known to be damaged.[1] I have had to deal with a number of cases of blackwater fever, and the profound and progressive anaemia associated with haemoglobinuria tempts one to seek the aid of blood transfusion. My early impressions of this remedy would have persuaded me to hail it with enthusiasm, but further experience has brought enough wisdom to curtail my ardour. In a series of cases I have realized that the earlier in the disease the transfusion was given, the worse were the results. In the early acute stage, when there may be suppression of urine and jaundice, and marked toxaemia, I have found blood transfusion to be an utterly useless remedy—in fact, I am inclined to think it has made things worse. The anaemia becomes complete, the toxaemia more marked, the pulse weaker, the heart dilates rapidly, and death soon closes the scene. This is the type of case in which the renal damage is definite and extreme, and blood transfusion does exactly what it did for Dr. Osman's nephritis case.

On the other hand, given a blackwater case in which the albuminuria has disappeared, urine with little or no albumin is passed in normal quantity, jaundice has disappeared, and the patient is left with a rapid pulse, a very grave anaemia, a low red cell count, and a high remittent temperature—all the features of post-haemoglobinuric fever—then, and only then, may we turn to blood transfusion as a valuable remedy. The stage of marked renal

[1] *British Medical Journal*, 1930, ii, 268.

damage has passed, and I have seen magical results from blood transfusion. The anaemia disappears, the temperature falls almost immediately, and the patient ceases to be a problem. The best result I have seen occurred in such a case where there was an interval of three weeks between the disappearance of the albuminuria and the transfusion. Patience is required in these cases; if the transfusion is hastened, disaster invariably threatens. I remember very vividly the case of a young man who was in this stage of post-haemoglobinuric fever with grave and progressive anaemia. His albuminuria had cleared, and five days afterwards I transfused 600 c.cm. of citrated blood. In about twelve hours the left ventricle margin had come out a full inch, there was complete anuria, and he succumbed rapidly.

I have had personal experience, and have known of cases in the experience of others, where blood transfusion has been urged and given as the remedy for that stage of blackwater fever in which are found grave toxaemia, jaundice, vomiting, and complete suppression of urine. Every patient without exception has died.

Dr. Osman draws attention to the possibilities of prophylactic alkalinization. If he tries this I am sure he will be disappointed. I have never given a blood transfusion in blackwater fever without it, and so my opinions are based on its routine use. Blood transfusion has a place in the treatment of blackwater fever. Out of its proper place it is destined to failure and disrepute.—I am, etc.,

Luanshya, Northern Rhodesia. JOHN PHILLIPS, M.B.Lond. F.R.C.S.Eng.

RUPTURE OF TENDONS

SIR,—Major C. M. Finny asks whether a rupture of the plantaris tendon has ever been demonstrated at operation. Since the publication of my paper in the *Journal* of April 11th, I have operated on a professional footballer who had sustained a complete rupture of the plantaris tendon at the same level. This combination of lesions I regard as exceptional.

Owing to the exigencies of space my paper contained merely a passing reference to that common lesion, partial rupture of the gastrocnemius or soleus, with its characteristic clinical picture so graphically described by Major Finny in his letter. The ambulatory treatment of this injury adopted by Major Finny is the correct one, and a similar regime is applicable in all partial muscle ruptures—namely, firm compression of the injured area by strapping or bandage, contractions of the muscle belly (induced if necessary by the faradic coil), and the avoidance of overstretching until sound healing has taken place.—I am, etc.,

Manchester, June 8th. HARRY PLATT.

TREATMENT OF DYSMENORRHOEA

SIR,—I have read with great interest Mr. Venn Dunn's paper on the treatment of dysmenorrhoea in the *Journal* of June 6th. Everyone will agree with him that the advances made in endocrinology call for a revision of the old classification into spasmodic and congestive types. There are, however, two statements in his paper which appear to call for modification.

He says that "In many cases of dysmenorrhoea the uterus is abnormally small." This statement should surely be modified to read: "In many cases of dysmenorrhoea the uterus *feels* abnormally small." From an experience of a large number of cases I have frequently been struck by the fact that the uterus feels small; but the passage of a uterine sound, and the measurement of its total length thereby, practically never reveals any shortening; on the contrary, the length of the cavity is often greater than 2½ inches.

In dealing with dilatation as a treatment for dysmenorrhoea, he states that "to be efficacious, dilatation must be sufficient. The cervix should be dilated up to No. 14. Further, the patient must be warned that the operation may have to be repeated in three months' time." With the first sentence of this paragraph I am in thorough agreement. The repetition of dilatation in three months' time is, in my experience, rarely necessary, provided that the dilatation in the first place is carried out far enough to secure paresis of the internal os.

Mr. Venn Dunn does not tell us what type of dilators he employs. I use Hawkins Ambler's pattern, and find that the highest number used to secure paresis varies greatly. It is rarely less than No. 26 of this pattern, and yet No. 36 may sometimes have to be used. To ensure that this amount of dilatation is carried out in safety it is wisest to divide the fibres of the internal os posteriorly, before any tearing takes place.—I am, etc.,

Liverpool, June 8th. A. A. GEMMELL.

CLOSED DRAINAGE IN THE TREATMENT OF EMPYEMA

SIR,—The description of his method by Dr. J. D. McEachern, given in the *Journal* of March 7th, and the question of priority in using the closed method in treating empyema raised by Dr. William Mitchell in a letter published on March 21st, clearly indicate the modern drift in the surgical treatment of abscessed conditions. Apart from that question, I would like to say at once that, to my way of thinking, Dr. McEachern does not make any claim to priority, and no doubt he will take an early opportunity to say so. Apart from the claim of others in this matter, we must not omit to mention Dieulafoy's method of intermittent drainage. The fact that modern practice has gone back to these primitive surgical times for ideas amazes me. The beautiful results which Lister obtained by open drainage, and his regard for that great principle in surgery that pus once discovered should be evacuated without delay, may be learned by the perusal of his addresses on the subject in the *Collected Papers*, and more particularly in a model clinical lecture published in the *Lancet* (1879, ii, 901). If anyone wants a swift, sure, and simple way of treating empyema, one within the limits of the most inexperienced surgeon, he will find it in the clinical lecture quoted above. A greater good will be done to surgery if we copy Lister's method rather than deliver panegyrics about him. Harvey's observations and experiments have been reproduced; why not Lister's? He is no more a back number than Harvey.—I am, etc.,

Brisbane, Queensland, April 28th. A. C. F. HALFORD, M.D.Melb., F.R.A.C.S.

ACUTE MASSIVE COLLAPSE FOLLOWING LIPIODOL INJECTION

SIR,—As an old-fashioned physician I still think that in the diagnosis of pulmonary disease, whether acute or chronic, we cannot dispense with a careful and full examination of the chest for direct physical signs. These signs are more varied and trustworthy than the signs, or rather shadows, obtained by means of *x* rays. *X* rays cannot show us the exact pathological condition or the exact import of any lesion. Over-confidence in *x*-ray diagnosis may lead to mistakes in diagnosis and treatment. The easy way to knowledge is not always the best or safest.

In criticizing the joint article of Dr. Scott Pinchin and Mr. Morlock it is my duty to say that a pain in the side of a healthy-looking young man of 18 (the site, intensity, and character of the pain being ignored), without cough or expectoration, and with "no physical signs except feeble breath sounds," hardly justifies a surgical operation under an anaesthetic, even though there was some suspicion of "fibrosis with bronchiectasis," in spite of the absence of any evidence, either in the history of the patient or by physical signs, to suggest such a possibility. I do not wonder, therefore, that "many hundreds of lipiodol examinations for many varying pulmonary conditions" have been made at the Victoria Park Chest Hospital.

Neither in the brief report of the state of the patient before the lipiodol injection, nor during the subsequent period, can I find any convincing evidence of acute massive "collapse of the lung on one side." We read: "At the time of the collapse the patient showed only slight respiratory distress." This condition developed in three minutes after the operation. There was "diminished movement, slight impairment of percussion note, and a considerable diminution of the air entry over the affected side of the chest" (rather a contradiction of signs). Verily a scanty array of phenomena upon which to base the diagnosis of acute massive collapse of the lung. There is no mention of altered breath sounds, bronchial, tubular, or of increased tussive resonance, and, strangest of all, no mention of displacement of organs, especially of the heart, towards the affected side.

To me it is hardly conceivable that acute massive collapse of the lung on one side could occur in three minutes without causing severe symptoms and disturbance of the heart's position and action. I should like to know the subsequent history. My own provisional diagnosis in this case would have been localized pleurisy—perhaps interlobar—perhaps mediastinal—perhaps diaphragmatic; or even a lesion in a subpleural gland. In any event a single intracutaneous injection of tuberculin might have excluded tuberculosis. Certainly lipiodol injections could not help in the diagnosis of localized pleurisy.—I am, etc.,

London, W., June 4th. W. CAMAC WILKINSON.

HAEMOLYTIC ICTERUS

SIR,—May I be allowed to make a note on Lord Dawson's first lecture on haemolytic icterus (published on May 30th), where he describes the origin of bile pigment? It is stated that "the origin of bile pigment is extrahepatic," as it had been shown by Whipple and Hooper in 1913 that bile pigment accumulated in the blood, followed by jaundice, "in dogs in which the liver had been isolated from the general circulation." After other observations it is stated to be "clear that the marrow and spleen are sites for the formation of bilirubin."

A paper on "haematogenous jaundice" was communicated by me to the Annual Meeting of the British Medical Association in 1895, and appeared in the *Journal* of January 18th, 1896 (p. 137). It was pointed out that up to that time the existence of such a form of jaundice was considered inadmissible. By treating rabbits with phenylhydrazin assisted by metaphenylendiamin, I showed that the bilirubin was formed in the spleen and carried to the liver, kidneys, etc., and that a haematogenous jaundice was not to be discarded. The work took me many months, but a full account will be found in the *Journal* referred to.—I am, etc.,

London, W.1, June 8th. A. G. AULD.

MATERNAL MORTALITY

A Disclaimer

SIR,—While some papers correctly, though briefly, reported an address which I gave before the College of Nursing post-graduate course at the London School of Hygiene on May 18th, others did not, and serious misstatements were included in certain reports. My official position normally precludes me from attempting to correct any perversion of my addresses or papers by communicating with the press. In the present instance, however, I fear that serious misunderstanding may arise from the incorrect attribution to me of a statement that if I had the supervision of maternity cases I could guarantee a reduction of three-quarters of the present average mortality. What I did say was that if effective medical and midwife supervision of maternity cases began early enough and was properly maintained up to and after childbirth, ultimately the maternal mortality rate might well be reduced by as much as three-quarters. This is indicated by the excellent results already secured in existing practice, which are recorded on page 106 of the interim report of the Departmental Committee on Maternal Mortality for 1930.—I am, etc.,

Ministry of Health, S.W.1, June 9th. GEORGE NEWMAN.

APLASTIC ANAEMIA

SIR,—In the paper by Drs. Fenton and Taylor in your issue of May 30th the case of aplastic anaemia does not seem from their account to have been investigated bacteriologically. Until such cases are, their etiology must remain a mystery. If cultures are made from the urine I have always been able to find a minute Gram-negative bacillus which I have not so far been able to put into any particular category; nor do I know whether there is a specific organism, or whether more than one organism can produce these conditions. One thing that is quite certain is the wonderful response pernicious anaemia—plastic and aplastic—makes to immunization with these microbes. I am writing in the hope that the urines of cases will be sent to me for investigation, so that my views as to etiology may be proved or disproved.—I am, etc.,

University College, Dublin, June 2nd. W. M. CROFTON.

NUTRITIONAL VALUE OF MILK

SIR,—The *Journal* of May 30th, 1931, contains a leading article on the Ministry of Health's recent memorandum on bovine tuberculosis in man. The article concludes with the following words: "Meanwhile, under careful methods of operation and scientific control, pasteurization can ensure a milk supply which is not only perfectly safe for consumption, but which retains its food value practically unimpaired by the heat to which it is subjected." This statement is a quotation from the memorandum, and is based solely upon a report on the pasteurization of milk which was issued by the Ministry of Health in 1923. In view of the great advances that have been made in our knowledge of nutrition during the past ten years it is astonishing that the Ministry of Health should have been content to rely upon an opinion which was expressed eight years ago.

The extensive experiments that have now been carried out for several years upon school children in Great Britain have made it clear that the addition of milk, even separated milk, to their ordinary diets has had a wonderful effect upon their health. These results demonstrate two things: first, that milk in any form is a wonderful foodstuff, and secondly, that the ordinary diets of the children

concerned were not adequate to produce the highest physical standard. Had that been the case, the great increases in height and weight within the time limits of the experiments could not have occurred. The truth of this probability is further confirmed by J. B. Orr and M. L. Clark's studies of the diets of 607 families in Scotland, from which they conclude that "the great majority were incapable of supporting the optimum rate of growth." The facts which have been related show that the study of the true nutritional values of the foodstuffs of the nation, and among them milk, is one of primary importance. This work has not yet been adequately carried out, but evidence is accumulating which indicates its urgent necessity.

The most recent experiment upon the effect of the addition of milk to the home diets of school children was carried out in Lanarkshire. In this experiment, which only lasted for about four months, 5,000 school children received daily three-quarters of a pint of raw Grade "A" (tuberculin-tested) milk, and 5,000 were given the same quantity of the same milk after pasteurization in accordance with the requirements of the Ministry of Health. In the report which Gerald Leighton and Peter McKinlay issued upon the results they state that "in so far as the conditions of this investigation are concerned, the effects of raw and pasteurized milk on growth in weight and height are, so far as we can judge, equal." These conclusions have been criticized by S. Bartlett, and R. A. Fisher and S. Bartlett. The latter state that:

"It seems evident that the conclusion should have been that the growth response in height to raw milk is significantly greater than that to pasteurized . . . . These results are put on record to avoid the danger that, from a superficial examination of the report, the conclusion should be drawn that this extensive experiment demonstrates the equivalence of pasteurized and raw milk. In reality the reverse is the case; and the very marked difference in response to two materials, which in their gross nutritional contents are so closely equivalent, raises a problem of very great interest, which can probably only be cleared up by more deliberate experimentation."

They further point out that the boys appeared to obtain much greater relative benefit than the girls, a conclusion which is confirmed by the work of E. C. V. Mattick and J. Golding, who fed generations of rats on raw, pasteurized, and sterilized milk, and found that the weights of the bucks were much more rapidly affected by the different types of milk than those of the does.

In America, also, the work of A. L. Daniels and G. Stearns; of M. Ladd, H. W. Evarts, and L. W. Franks; and of M. S. Lewis, upon the feeding of infants up to 12 months of age, appears to demonstrate that there is a real difference in the nutritional values of fresh milk and milk that has been treated by heat. Those who study the chemistry of milk know well its extreme complexity and the very delicate state of balance in which its constituents exist, a balance which cannot be replaced easily if it is once altered.

The influence of nutrition upon the incidence of disease is undoubtedly great. This has long been recognized by those who have studied the effects of war or famine upon the health of nations, but it is improbable that we have appreciated its importance in our daily lives sufficiently. Recent work, however, as for example that of R. McCarrison, and of J. B. Orr, J. J. R. Macleod, and T. J. Mackie, is bringing home to us the necessity for its more complete study.

These facts are set out because of their importance to the nation and to the milk industry, since recent publications indicate that many people desire the compulsory pasteurization of practically the whole of the milk supplies of our great centres of population. This procedure has hitherto led to the almost entire extinction of fresh milk in the cities of those countries which have adopted it. The question whether we shall or shall not follow in their footsteps is one of very great gravity, which should only be decided after most careful consideration of all the issues involved.

Those who are within the milk industry know well the very great advances it has made within the last ten years under a voluntary system of licensing which has only been in existence for a short time. They realize the vast improvements that have taken place in the supplies of pasteurized and other forms of treated milk which are sold in our cities, and along with them the increasing production of fresh milk from cows which do not react to the tuberculin test, and its sale at a reasonable price in provincial towns, and even in districts like Bermondsey in London. In Reading, for example, Grade "A" (tuberculin-tested) milk amounts to about one-fifth or one-sixth of the total milk supply, and there is no reason why this should not be the case in other towns in England.

The greatest credit is due to the milk industry for the work which is being accomplished, and it would be a great pity if any action were taken which hindered its progress.—I am, etc.,

R. STENHOUSE WILLIAMS.

National Institute for Research in Dairying, Reading, June 1st.

TREATMENT OF BRAIN ABSCESS

SIR,—Mr. Courtenay Yorke, in his account of an acute cerebellar abscess following closely on acute mastoid infection, states that a knife was inserted into the cerebellum to a depth of one inch in different directions, but without result. A Record syringe with a stout needle was then tried, and at a depth of one and a half inches one drachm of pus was withdrawn. On the strength of this success Mr. Yorke appears to advocate the use of the hypodermic syringe as a searcher. Surely it was the depth to which the searcher penetrated, and its direction, which determined failure or success. Then Mr. H. V. Forster, in a letter, proclaims his "enthusiasm" for the hypodermic syringe method, and rather naïvely remarks: "If the findings are negative, then there is either no brain abscess or it is out of reach, or has not been entered by the needle." What Mr. Punch would call "Another glimpse of the obvious"!

It is rather surprising to find aural surgeons of the stamp of Mr. Yorke and Mr. Forster advocating finicking and "rest and be thankful" methods of operating on otitic brain abscesses. It is true that some abscesses recover by whatever method they are opened and drained, but there are many that do not, and it is to the treatment of this type of case on true surgical lines that the attention of otologists should be directed.—I am, etc.,

Upper Bangor, June 7th. HUGH E. JONES.

INJECTION TREATMENT OF HAEMORRHOIDS

SIR,—The report in the *Journal* (May 23rd, p. 898) of the discussion on the injection treatment of piles at the Royal Society of Medicine makes it appear that I was condemning the interstitial carbolic-glycerin method, whilst praising by comparison not only other injection methods, but also surgical operation. My remarks should have conveyed almost the opposite meaning. The inaccuracy of the report may have been partly my fault in not making my meaning clear, as I am an unpractised speaker.

I stated that an extensive practical experience of over fourteen years had confirmed me in my opinion of the efficacy of injection, which I considered the treatment of choice for suitable cases, but thought its scope more

limited than was formerly my opinion. My remarks were principally a plea that the injection method which gave such " excellent " results in skilled hands should not be exposed to the risk of discredit by extravagant statements claiming for it almost universal applicability. For this reason I confined my comments to the factors which should determine the type of case suitable for treatment and the correct technique and solution of choice. My definition of " uncomplicated " haemorrhoids from the point of view of injection as " piles which contained little fibrous tissue and in which the veins were not much fibrosed " explains, I stated, the type of case suitable, and also accounts for success or failure with injections. In skilled hands injection cured this type of case rapidly and painlessly, but here we had the limitations of injection treatment as a safe and permanently effective method.

I did not suggest that ligature was the best and injection the next best method. Ligature was best for " complicated " cases, especially as the technique affected only an area less than the size of the pile ; on an average less than an inch of mucous membrane was involved. The injection method which approximated most to this was best. The interstitial carbolic-glycerin method which I advised (it was first advocated by my teachers, Mr. Swinford Edwards and Mr. Lockhart-Mummery) was therefore ideal, as the small dosage necessary (3 minims to at most 10) was injected into the pile alone. Injection cured solely by its action on the veins, causing thrombosis leading to sclerosis and shrinkage ; thus haemorrhage and prolapse were cured. No injections (not merely carbolic and glycerin, as the report suggests) could get rid of fibrous tissue unless excessive strength of dosage was used, causing painful sloughing and proctitis, which may last several weeks, with possibly dangerous haemorrhage. This condition is worse than can result from operation ; for such cases ligature under local anaesthesia was simpler, safer, and comparatively painless, and a combination of injection and ligature for the same case was frequently best. I told the meeting I had seen such cases in the hands of those who had recorded them without understanding the cause. The ligature operation was, however, as unnecessary and drastic for " uncomplicated " piles as injection was unsuitable for the other variety ; there is an extensive field within which each is the method of choice.

As to the injection technique of choice, the meeting was asked to decide between the *interstitial* glycerin-carbolic method and the *submucous* carbolized oil method. The greater part of my remarks were devoted to this point. I condemned the out-of-date but rediscovered submucous carbolized oil method advocated by several speakers, as I had previously done (*Journal*, September 20th, 1930, p. 498), as retrograde, dangerous, and unnecessary. My reasons were that the large dosage employed (some advised 10 to 15 c.cm.) had to be injected " to a height until the mucous membrane ceased to be loose, beyond Houston's valves if necessary," to procure a generalized inflammation sufficient to make the mucous membrane adhere permanently to the rectal muscle and thus effect cure, " but the haemorrhoids still remained uncured unless injections were also made down to their level." With this technique, therefore, more than half the rectum was involved even in average cases, the mucous membrane becoming " hard as parchment." When, however, the reaction is excessive the whole rectum becomes acutely affected, and a dangerous and painful condition results. I said I had seen such cases, and the literature records numerous instances. It seemed to me unnecessarily drastic treatment to damage the whole rectum in order to cure a few piles in the lowest inch of the bowel ; it was difficult to see how its sponsors could call it an " improved technique." I assured the meeting that if permanent adherence occurred " patients would be damaged for life, as the rectal mucous membrane was normally loose and should be left so, its free movement on the rectal muscle being necessary during defaecation." This alone was sufficient to condemn the submucous oil method (or any submucous method), which is simply a bludgeoning attempt by some who are ignorant of the rationale of the treatment (that is, who deny that cure is effected by thrombosis) to cure every type of pile, whether suitable or not, by injection. The eminent proctologists who introduced injection treatment to this country, and who still advise the interstitial method, never claimed almost universal applicability, but were careful to indicate the limitations of injection whilst extolling its merits.

I was alone in condemning the submucous oil method, and described a pitiful case I had seen in which pyrexia, rigors, and generalized proctitis occurred ; the patient was completely disabled for two months. I was also the only speaker who considered it necessary to give reasons, anatomical and pathological, for the approval or disapproval of the methods advocated. During many years past, when those who are now advising the submucous carbolized oil method were advocating large doses with the interstitial method (as much as 40 minims of the 20 per cent. carbolic-glycerin solution, instead of the 10 minims which I advised as a maximum), I warned the general practitioner that this procedure was dangerous, and that sloughing, ulceration, and proctitis would be liable to result, due to excessive thrombosis. (Their disastrous technique was founded on their erroneous belief that thrombosis seldom or never occurred with injection, whereas pathologists have demonstrated that it almost invariably occurs.) I again warn the profession that if this oil method becomes widely practised, especially if it is " forced " in an effort to cure unsuitable types of haemorrhoids, disasters will be increased manifold ; I have seen them, and the literature records many instances. These points should be made known to the general practitioner, and I was the only one to do so. Mr. Perrin and Mr. Turner Warwick, whose contributions were such an instructive feature of the discussion, were good enough *to say that they agreed with my opinions, and in fairness* to your readers the disadvantages and dangers of this alleged " new and improved " method of treatment should be indicated.—I am, etc.,

London W., June 3rd. P. KENNEDY MURPHY.

A SUBSTITUTE FOR HAND TOWELS

SIR,—When in Paris recently I was amused to see at the Gare St. Lazare a new method of " drying " one's hands after washing. After washing my hands with the ordinary French powder soap I searched hopelessly for a towel, until somebody indicated a foot pedal in the corner. This started a motor which blew hot air through the outlets of two pipes, about a foot apart, one delivering upwards, the other downwards. One's hands placed between the pipes became dry in a few seconds. This machine may be familiar to some of your readers, but it was new to me. Hygienically, it seems an improvement on the communal English roller towel, the impossibly expensive single towel for each person, or the uncomfortable American sheets of crinkled paper. What the cost of the machine or its maintenance is I do not know. I made a note of the address on it: *Sogenex, 80, Rue F.* St. Denis.—I am, etc.,

June 2nd. D.P.H.

ETIOLOGY OF ULCERATIVE COLITIS

SIR,—In the article by Dr. Arthur F. Hurst, which appeared in your issue of April 25th, the following sentence appears: "Several American physicians have told me that they have been quite unable to confirm Bargen's enthusiastic reports about vaccination with his organism, which has not been accepted by any other American workers as the cause of ulcerative colitis." I would like to point out that the final clause gives scarcely an accurate impression. The enclosed list of articles is only a portion of a number that have appeared, in which our work has been confirmed.—I am, etc.,

Mayo Clinic, Rochester, Minnesota, May 22nd. J. A. BARGEN.

Obituary

A. T. MACCONKEY, M.B., B.CH., D.P.H.

Late Bacteriologist in Charge, Serum Department, Lister Institute

The death of Dr. Alfred T. MacConkey, on May 17th, at the age of 70, recalls to bacteriologists his early researches connected with the bacteriology of sewage and water supplies. It was his work for the Royal Commission on Sewage Disposal which led him to devise the culture media known by his name. The most distinctive feature of the liquid and solid MacConkey media was the use of bile salts in order to inhibit the growth of bacteria not derived from the intestine, and so to recognize those of faecal origin. He also incorporated glucose or lactose with the bile salt in the nutritive media. Later the commonly used "MacConkey agar" always contained not glucose, but lactose and neutral red, so that not only were the characteristic intestinal bacteria given an advantage over other forms, but also colonies of various pathogenic bacteria in faeces which did not ferment lactose were made conspicuous and differentiated from the non-pathogenic *B. coli*. In spite of the many other prescriptions for media intended to fulfil the same purpose, "MacConkey agar" is still used in this country and in other parts of the world in preference to its many rivals, especially by British workers, on account of its simplicity and effectiveness. When MacConkey began to work for the Royal Commission in 1899 the knowledge of the great variety of bacteria present in faeces and their differentiation from others commonly found in water was very elementary. The task in this field of work must have appeared overwhelming. MacConkey became intensely interested in the important problems involved, and by his enthusiastic and persistent work added considerably to our knowledge of the most useful means of distinguishing the bacteria, generically called *B. coli*, which were of recent intestinal origin from others associated with cultivated and uncultivated soils, and he helped to investigate the distribution in nature of the various somewhat similar bacteria, especially *B. lactis aerogenes*. Between 1900 and 1909 he published several papers on aspects of the same subject.

Alfred Theodore MacConkey began his medical studies at Cambridge, where he took an honours degree in Natural Science. After subsequent work at Guy's Hospital he graduated M.B., B.Ch. in 1889, and then served as house-surgeon at that hospital. He was in practice for some years at Beckenham, but illness following influenza determined his retirement from practice and devotion to bacteriology. In 1901 he joined the staff of the Lister Institute at Chelsea, and very soon was transferred to the serum department of the Institute at Elstree. In 1906, when Dr. George Dean retired, Dr. MacConkey succeeded him as bacteriologist in charge of the serum department, and thenceforward his interests lay in the technique of preparing serums. He devoted himself with characteristic attention to detail to the production of toxins and other antigens, the care and inoculation of the animals, and the management of the laboratories and farm. He took great personal interest in the individual horses, showing much kindly feeling for them. His work in producing therapeutic and prophylactic serums he looked on as a form of public service The enthusiasm with which he rapidly enlarged the stables and laboratory accommodation during the war in order to make greatly increased supplies of serum for the Expeditionary Forces was for him an expression of his desire to be of use to the country. He was especially interested in antitetanic serum, and published several papers on its value and in exposition of his belief that it should be used more actively as a therapeutic agent. He was always ready to give help and the benefit of his experience to visitors from other serum institutes and to those starting to make medicinal serums in various parts of the Empire. His kindly advice, and hints warning beginners against avoidable difficulties, must have proved of great value to many who sought his assistance.

Dr. and Mrs. MacConkey delighted to entertain visitors from all over the world and to display his remarkably successful garden, in which he spent so much of his leisure. After 1926, when he retired from his post at Elstree, he lived at Blindley Heath in Surrey, and continued to gratify his love for the culture of flowers, especially roses.

J. A. A.

There recently died in a Dublin hospital Daniel Crowly, formerly a student of Queen's College, Cork, who graduated M.D. in 1888 at the old Queen's University. Until quite lately he carried on a large practice in the town of Loughrea and the surrounding part of County Galway, and was much esteemed. He recently resigned the coronership of the County Galway (Southern Division), and at that time he was probably the last survivor of those who had been elected to the office by vote of all the electors on the parliamentary franchise of the county; it speaks much for the charm of his personality and character that he should have been elected by popular vote in a county where clannishness was such a dominant factor. Dr. Crowly is greatly regretted by his colleagues, who could always rely on his helpful kindliness and consideration. They offer their sympathy to his widow and son, Albert Crowly, who is also a member of the medical profession.

J. M.

The following well-known foreign medical men have recently died: Dr. JEAN DUMONT, secretary of the *Presse Médicale*, aged 63; Professor AXEL HOLST, the eminent bacteriologist and hygienist of Oslo, aged 71; and Dr. J. WAGENHAUSER, formerly professor of otology at Tübingen, aged 81.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

At a congregation held on June 6th the following medical degrees were conferred:

M.D.—R. M. B. MacKenna, C. C. R. Downing, J. P. Marsden, M. E. Lampard.

M.B.—H. L. Hoffman.

B.CHIR.—C. O. Barnes.

Sir Humphry Rolleston, Bt., Regius Professor of Physic, has been appointed to represent the University at the celebration of the 250th anniversary of the Royal College of Physicians, Edinburgh, from November 29th to December 1st, next.

Presentation to John Lane

The completion of fifty years' service by John Lane, chief assistant at the Anatomy School, was celebrated in the large lecture theatre of the Anatomy School on June 2nd, when Mr. Lane was presented with a gold watch and chain and a cheque for 105 guineas. The Vice-Chancellor of the University honoured the occasion with his presence, and Professor Wilson presided over a large and enthusiastic gathering. Miss Macalister represented the family of the late Professor Macalister. Letters expressing regret for absence were read from Sir Donald MacAlister and Professor E. Barclay Smith. Before making the presentation, Professor Wilson called upon the senior members of the presentation committee to report on their proceedings. In response, Dr. Duckworth and Mr. Hopkinson recounted the progress of their appeal, and illustrated its success by reference to the large number (1,066) of those who had contributed. Particular reference was made to the co-operation of Cambridge men now holding prominent positions on the staffs of the principal London hospitals. Thanks to their devoted efforts, the presentation had been brought to the notice of a large number of medical graduates and of students who, having left Cambridge, were now engaged in clinical work in London. Warm acknowledgement was also made of the assistance rendered by the committee and college representatives of the University Medical Students' Society, whose president was a member of the presentation committee. Professor Wilson then made the presentation, and Mr. John Lane made a brief but effectively appropriate and grateful reply. The inscription inside the cover of the watch was as follows:

"1881–1931. The presentation of this watch marks the completion of John Lane's 50th year of service in the Anatomy School, and assures him of the warm appreciation of that service by those who have combined to make the gift."

UNIVERSITY OF LONDON

The following have been recognized as teachers of the University at the medical schools indicated. Westminster Hospital Medical School: Mr. E. P. Brockman (orthopaedic surgery), Mr. C. P. Thomas (surgery), Mr. Reginald Worth (mental diseases); London Hospital Medical College: Mr. Victor W. Dix (surgery), Mr. W. S. Herman (dental surgery), Mr. E. P. Stibbe (anatomy); Charing Cross Hospital Medical School: Dr. C. W. Hutt (hygiene).

Regulations for Examinations

The regulations for the M.D. and M.S. examinations for internal students have been amended by the addition of the following sentence at the end of the first paragraph on page 219, and the last paragraph but one on page 224 of the Red Book, 1930–31:

In the pass list a mark of distinction will also be placed against the names of all candidates who, in the opinion of the examiners, have qualified for the award of a University medal, irrespective of whether the medal is awarded to them or not.

The regulations for the M.D. and M.S. examinations for external students (Blue Book, September 30th, 1930, pp. 271 and 276) have been similarly amended.

It has been decided that in and after 1932 the regulations for the academic diploma in public health be amended by the substitution of the following for the last paragraph on page 468 and the first paragraph on page 469 (Red Book, 1930–31):

(1) Part I of the examination will be held twice a year, beginning on the first Monday in April, or, if that be a bank holiday, on the second Monday in April; and on the Monday of the week prior to the first Tuesday in July.

(2) Part II of the examination will be held twice a year, beginning on the Monday in the week following that in which the June–July examination for Part I is held; and on the fourth Monday in September.

It was also decided that in 1931 Part II of the examination shall begin on the Monday in the week following that in which the September examination for Part I is held, and not on the Tuesday in that week, as provided in the existing regulations.

Mickle Fellowship

Applications for the William Julius Mickle Fellowship must reach the Principal of the University by October 1st. It is of the value of at least £200, and is awarded annually to the man or woman who, being resident in London and a graduate of the University, "has, in the opinion of the Senate, done most to advance medical art or science within the preceding five years, and has therein shown conspicuous merit. Full particulars can be obtained on application to the Academic Registrar, University of London, S.W.7.

The following candidates have been approved at the examination indicated:

THIRD M.B., B.S.—§*H. W. Howell, §*L. H. Howells, §*Alison F. Z. Judd, §†Muriel H. E. Long, §‡‖P. V. Reading, §‖T. F. Todd, §‖Marion E. Townsend, R. M. Alderton, Gwendolen E. Austin, F. Back, E. E. SOCIETY OF APOTHECARIES OF LONDON

The following candidates have been approved at the examination indicated:

MASTER OF MIDWIFERY.—A. V. Clemmey, B.M., B.Ch.Oxf., A. Gardiner, M.B., B.Ch.Glas., Greta Hartley, M.B., B.S.Lond., Eva J. Newton, M.B., B.S.Lond.

The Services

SHORTAGE OF MEDICAL OFFICERS IN THE SERVICES

COMMITTEE OF INQUIRY

A committee, constituted as follows, has been appointed by the Prime Minister to investigate the causes of the shortage of officers and nurses in the medical and dental branches of the three defence Services, and to recommend by what means the situation can be remedied: Sir Warren Fisher, Permanent Secretary to H.M. Treasury (chairman); Mr. C. L. Bullock, Secretary of the Air Ministry; Sir Herbert Creedy, Permanent Under Secretary of State for War; Mr. H. E. Fass, Principal Assistant Secretary to the Treasury; Lieut.-General Sir Harold Fawcus, Director-General Army Medical Services; Professor G. E. Gask, Director of the Surgical Unit, St. Bartholomew's Hospital; Surgeon Vice-Admiral Sir Arthur Gaskell, Medical Director-General Royal Navy; Dr. A. M. H. Gray, Dean of University College Hospital Medical School; Air Commodore J. McIntyre, Director of Medical Services Royal Air Force; Sir Oswyn Murray, Secretary of the Admiralty; and Sir S. Findlater Stewart, Permanent Under Secretary of State for India. The secretary of the committee is Mr. W. Lindsay Scott of the Air Ministry.

RECEPTION AT R.A.M. COLLEGE

The officers of the Royal Army Medical Corps held a reception at their headquarters mess at Millbank on the evening of Thursday, June 4th. The guests were received by Lieut.-General Sir Harold Fawcus (Director-General, Army Medical Services) and Lady Fawcus, and the large company present included the President of the General Medical Council, the Presidents of the Royal Colleges of Physicians and Surgeons, leading representatives of the metropolitan medical schools, and many other members of the profession in London. The laboratories and lecture rooms of the Royal Army Medical College were on view during the evening.

DEATHS IN THE SERVICES

Surgeon Rear-Admiral John Hutton Stenhouse, R.N. (ret.), died in a nursing home in Edinburgh, on April 4th, aged 65. He was educated at Aberdeen University, where he graduated as M.B. and C.M. in 1886, and, entering the Navy soon after, attained the rank of rear-admiral on July 3rd, 1920. He served through the war of 1914–18, receiving the medals.

Surgeon Captain William Kenneth Dudoit Breton, R.N. (ret.), died on April 4th. He was educated at St. Mary's; took the M.R.C.S. and L.R.C.P.Lond. in 1902, and after holding the posts of resident medical officer at St. Mary's and house-surgeon and dental house-surgeon at the West London Hospital, entered the Navy. He attained the rank of surgeon commander on January 1st, 1917, and retired, with an honorary step as surgeon captain, on August 10th, 1925. He served throughout the war of 1914–18, receiving the medals.

Major Douglas Noel MacLeod, R.A.M.C., died in the Cambridge Military Hospital at Aldershot on May 9th, aged 44. He was born on December 25th, 1886, the younger son of the late Dr. Neil MacLeod of Shanghai, and was educated at Cambridge, where he graduated B.A. with honours in the Natural Science Tripos in 1907, and at Birmingham, where he graduated B.Ch. in 1911, and M.D. in 1913. After filling the posts of house-surgeon and house-physician in the Queen's Hospital, Birmingham, he joined the R.A.M.C. when the war began, as a lieutenant in the Special Reserve, before the end of 1914, took a permanent commission as lieutenant on January 1st, 1917, and became major on November 25th, 1926. He served throughout the war of 1914–18, and was mentioned in dispatches in the *London Gazette* of May 29th, 1917. He had only recently returned to England from Cairo.

Medico-Legal

CONVICTION FOR FALSELY PRETENDING TO BE A MEDICAL MAN

At Warrington police court on May 29th, D. Tindall, or Richard Tindall, of Warrington, was summoned by the Medical Defence Union on four charges—two of falsely pretending to be a bachelor of medicine, another of falsely using that title, and a fourth of pretending to be a general practitioner in medicine. He was fined £5 on each of the four summonses—£20 in all—with the alternative of one month's imprisonment on each summons.

Mr. T. S. Steel, solicitor, who conducted the prosecution, said that Tindall was an undertaker and certified embalmer. He had claimed to be a fully qualified medical man, holding the degrees of M.B., Ch.B. (which was printed on his visiting cards), and stated that he was a member of the Royal College of Surgeons, had issued prescriptions which were made up by local chemists, and had presumed to treat professionally people suffering from various diseases. He claimed to have acted as an anaesthetist to three prominent Manchester practitioners, to have made application for the post of anaesthetist at Warrington Infirmary, and to have interviewed the clerk of the local insurance committee with a view to starting an insurance practice in Warrington.

Mr. George Sturgess, solicitor for the defence, said that Tindall served in the R.A.M.C. during the war, and his duties in that capacity created in him a desire to be a medical practitioner. He failed to pass matriculation, but he had a library of medical books, and had studied the subject. He was the victim of a pathetic ambition.

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

The House of Commons was in committee on the Finance Bill for four days this week.

On June 9th the House of Lords gave second readings to the Housing (Rural Workers) Amendment Bill and the Merchant Shipping (Safety and Load Line) Bill. The Widows', Orphans', and Old Age Contributory Pensions Bill passed through committee.

The Parliamentary Medical Committee and other members of the House of Commons were addressed by Sir Leonard Hill on June 9th, his subject being the ventilation of the House of Commons. Dr. Salter presided. Sir Leonard Hill said he objected to the present system, whereby air entered the House through the floor. He proposed the admission of a stream of cool air at the level of the gallery, to descend on the heads of members. If desired, hot-water pipes could be installed under the feet. Comfort was best secured when the air was cool but the walls warm. He suggested that the Chamber and other rooms of the House should be heated at night and then flushed out with cool air. Tests made in the Chamber had shown that the present upward current carried away infectious spray from the mouth. There was more danger of infection when members talked and coughed in the division lobbies.

A discussion followed Sir Leonard Hill's address. Speakers agreed that the improvement of ventilation was not only desirable in the Chamber but in the committee rooms and the library. Mr. Lansbury suggested that there should be a further inquiry into the ventilation of the whole building.

The Budget: Petrol Tax

On June 8th the House of Commons began consideration of the Finance Bill in committee. Clause 1 increases the Customs duty on hydrocarbon oils from 4d. to 6d. a gallon.

Dr. Fremantle and other members had put down amendments to exempt from the duty petrol used by medical practitioners and veterinary surgeons in carrying on their medical and veterinary practices, and petrol used in hospital ambulance work.

During the debate on the motion that Clause 1 should stand part of the Bill, Dr. FREMANTLE said under the guillotine resolution they were compelled to pass over a number of amendments to the clause which were of definite importance. As illustrations, he mentioned two amendments, in which he was particularly interested—amendments which suggested exemption in the case of ambulances attached to hospitals and in the case of medical and veterinary practitioners. There were precedents for these proposals, and he only spoke of them as illustrating the damage which could be done by imposing a general duty of this sort without giving time for the consideration of exemptions. In the Finance Act, 1910, which originally imposed the motor spirit duty, medical men were given a rebate of half the duty in respect of motor cars owned and used by them in carrying out the duties of their practices. As regarded ambulances, there was also a definite precedent; at present, lifeboats were exempt. Why, then, should ambulances of hospitals be taxed? They were required more than ever to-day, because of the increasing number of road accidents. The cost of those accidents was not paid by the Government, and was not, to any large extent, borne even by the people who suffered. To a large extent they were borne by the voluntary hospitals, the ambulance services, and the St. John Ambulance Association. A very small proportion was paid by the people who had the benefit of these services. He knew that in theory the Government proposed to their Socialist supporters that there should be Socialistic services of this kind and that all those things should be run by the State. On the other hand, they came to the House of Commons and said, "We have to take things as they are." Then they put even greater burdens on the people who

already had to bear the handicaps of this service. They said that they were compelled to do so pending the nationalization of those services. There might one day be the nationalized medical service proposed by Mr. Hastings, but it would be a long time before it came. It would be the acid test of the theory, because people would then have an opportunity of realizing the rights and wrongs, the advantages and disadvantages, of a mechanical system. This clause would add considerably to the cost of running ambulances and to the expenses of the country doctor. He reckoned that to the ordinary country doctor who covered 20,000 miles a year, and whose car did twenty miles to the gallon, the extra 2d. would cost an extra £10 a year. Therefore the clause would place an additional burden of £10 a year on the country doctor who used his car in order that he might get more quickly about his district and attend the people under his care. There was a definite case which the Government ought to face.

The clause was agreed to.

Vaccination

Mr. FREEMAN put a question, on June 4th, concerning a boy aged 7, who (he alleged) had lost the sight of his right eye as a result of vaccination by the public vaccinator at Dagenham in October, 1930, while under treatment at the same time for a septic knee. Mr. GREENWOOD said his attention had been drawn to the case. The vaccination had been performed with the consent of the parents, and the public vaccinator found no physical reason why the boy should not be vaccinated, nor did he observe any evidence of an affection of the eye when he inspected the vaccination on November 4th. It was not until thirty-six days after the date of vaccination that the boy was taken to the school clinic at Barking on account of eye trouble. Mr. Greenwood was advised that the course of events was not consistent with the suggestions which had been made that the affection of the eye was the result of the vaccination, or that vaccine entered the eye at the time of vaccination. Mr. FREEMAN asked whether the Minister knew that the parents of the child were not present at the vaccination, and whether any medical examination of the child took place to show that he was in a fit state to stand the result of the operation, Mr. GREENWOOD said the public vaccinator was himself a medical man and he should accept his report. The Minister could not say without notice whether an inspection of the child was made or whether the public vaccinator found that there was a septic condition at the time. It was very difficult to say that medical evidence, or an examination of the child, could prove vaccination was the cause of the blindness, when the additional disability was discovered well after a month from the vaccination.

Replying to Mr. Freeman, on June 4th, Mr. GREENWOOD said the circumstances of the death at South Wigston, near Leicester, of twin children, both considered to be in good health, who were vaccinated on May 14th and died on May 29th and 30th respectively, had been inquired into by a medical officer of his department, and pathological investigations were now in progress. He would communicate with Mr. Freeman when the results were available. He could not say without notice whether Government lymph was used in this case, or whether public vaccination had now ceased in that district.

Small-pox

Miss LAWRENCE, on June 2nd, stated that there were 11,839 cases of small-pox among the civilian population notified in England and Wales (including port sanitary districts) during the fifty-three weeks ended January 3rd, 1931. Of the total deaths registered in England and Wales during 1930, 28 were classified to small-pox.

Committee on Food Standards

On June 4th, in reply to Mr. R. J. Russell, Mr. GREENWOOD stated that a Committee on Food Standards had been set up to inquire into the working of the law as to the composition and description of articles of food other than milk, and to report what alterations, if any, in the law or its administration appeared to be desirable. The members of the committee were Sir Frederick Willis (chairman), Mrs. J. L. Adamson, Mr. W. Barratt, Mrs. E. Beck, Mr. J. N. Beckett, Mr. G. A. Birse, Mr. H. F. Carlill, Mrs. M. E. Cottrell, Mr. A. T. A. Dobson, Mr. H. E. Goodby, Dr. J. M. Hamill, Mrs. Jean Roberts, Mr. R. A. Robinson, Mr. H. Shaw, and Mr. G. Stubbs.

Sale of Butter

Replying to Captain P. Macdonald, on June 2nd, Miss LAWRENCE said that an examination was made of butter imported into Great Britain for sale. Butter exposed for sale might be seized and destroyed if found to be unfit for human consumption. Samples were taken by officers of local authorities under the Food and Drugs (Adulteration) Act and the Sale of Butter Regulations, and the vendor was liable to prosecution if there was evidence of adulteration. Answering Colonel Ruggles-Brise, Miss LAWRENCE said that samples of recent consignments of Russian butter had been found on analysis to be genuine. She was having further samples examined bacteriologically.

Supervision of Nursing Homes.—Mr. GREENWOOD told Mr. West Russell, on June 4th, that under the Nursing Homes Registration Act, 1927, the London County Council was the local supervising authority for private nursing homes in the metropolitan area outside the City of London, and a complete statment of the present position would be included in the Council's report for 1930, which was now in preparation.

Indian Hospitals and Dispensaries.—Mr. BENN, in reply to Mr. Freeman on June 4th, said that in 1928 there were 552 State-public hospitals and dispensaries in British India, 3,713 local fund institutions of the same character, and 306 privately aided institutions. During that year 888,651 indoor and 49,229,903 outdoor patients were treated at these institutions.

Tuberculosis in H.M.S. Warspite.—On June 8th, Mr. G. HALL told Sir B. Falle that the number of cases of tuberculosis which had occurred in H.M.S. *Warspite* since she recommissioned on January 23rd, 1929, was thirteen, of which eleven had been invalided and two had died in hospital. Sir B. FALLE asked Mr. Hall specially to inquire into this matter and ascertain why there had been so many cases, and how many of these men had been pensioned. Mr. HALL replied that eight were pensioned out of thirteen. An inquiry had already been held, but unfortunately they were not able to ascertain the actual cause of the very high percentage of cases in 1929.

Veterinary Medical Research.—Dr. ADDISON told Mr. C. Williams, on June 8th, that he could not say at present whether it would be necessary for him to ask the House to pass a supplementary estimate to carry out the scheme now being prepared for the development of veterinary medical research.

Medical News

In the list of medical men included in the Birthday Honours, published last week at page 1004, we accidentally omitted the name of Lieut.-Colonel Thomas Reginald St. Johnston, C.M.G., Governor and Commander-in-Chief of the Leeward Islands, who receives the K.C.M.G.

On the afternoon of Tuesday, June 30th, H.R.H. The Duchess of York, President of St. Mary's Hospital, will lay the foundation stones of the new medical school and pathological institute, and the Right Hon. Stanley Baldwin will give a short address. The operating suites, wards, and laboratories of the hospital will be open for the inspection of visitors.

The next meeting of the Biochemical Society will be held at the Marine Biological Station, Plymouth, to-day (Saturday, June 13th), at 3.30 p.m.

Sir W. R. Morris, Bt., will distribute the prizes at St. Thomas's Hospital Medical School on Wednesday, June 24th, at 3 p.m. The whole hospital will be open for inspection during the afternoon.

Lord Macmillan, chairman of the University Court of the University of London, will distribute the prizes at the London Hospital Medical College on Wednesday, June 24th, at 3 p.m.

Sir Robert Horne will be the principal speaker at the dinner to be held by the British Science Guild at the Hyde Park Hotel on Friday, June 19th, with Sir Samuel Hoare in the chair.

The Home Secretary, Mr. J. R. Clynes, will speak at the annual meeting of the National Institute for the Deaf, to be held at the Church House, Westminster, to-day (Friday, June 12th), at 3.30 p.m., when Dr. F. E. Fremantle, M.P., will preside. The meeting is a public one, and those who are interested in deafness and the welfare of those suffering from it are invited to attend.

The annual meeting of the Incorporated Lancashire and Cheshire Society for the Permanent Care of the Feeble-Minded will be held at the Sandlebridge Institution, Alderley Edge, on Wednesday, June 17th; the Lord Mayor of Manchester will take the chair at 3.15 p.m. The Thomasson and Sam Gamble Day School will be open for inspection at 2.30 p.m., and tea will be served at Warford Hall at 4 p.m.

Particulars of the lectures and demonstrations arranged for next week by the Fellowship of Medicine will be found at page 244 of the *Supplement*. The special evening lectures to candidates for the M.R.C.P. are being continued. Syllabuses and tickets for all the courses may be had from the Fellowship of Medicine, 1, Wimpole Street, W.1.

The secretary-general asks us to state that the second International Congress for Light will be held in Copenhagen in *1932* and not this year. A detailed programme will be issued in the autumn of this year.

The first International Neurological Congress, the foundation of which was suggested by the late Professor Hermann Oppenheim in 1912, will be held in Berne from August 31st to September 6th under the presidency of Dr. B. Sachs of New York. The four official languages will be English, French, German, and Italian.

On Sunday, June 7th, H.R.H. Princess Victoria visited Gerrard's Cross, and in the parish church unveiled a tablet which has been placed there to the memory of the late John Llewelyn-Jones, M.D.Lond., J.P., well known in South Bucks, who died in February, 1930. A short address was given by Mr. D. Cotes-Preedy, K.C., Recorder of Smethwick, himself a member of the medical profession and an old friend of the deceased. A large congregation testified to the esteem in which—to quote the words on the tablet—"a beloved physician and steadfast friend" was held.

At a special meeting of the Royal Society of Medicine, held on May 19th, a resolution was adopted abolishing the Sections of Balneology and Climatology and of Electro-Therapeutics. It was also decided to establish in substitution thereof a Section of Physical Medicine, which shall have for its object the study of balneology, climatology, and electrology, and ancillary subjects, and also a Section of Radiology for the study of radiology and subjects relating thereto.

Commemoration Day at Livingstone College, Leyton, was held on June 4th, when the chair was taken by Mr. W. McAdam Eccles, F.R.C.S., the visitors including many representatives of missionary organizations. The chairman recalled that some thirty-nine years ago Dr. Harford, Dr. Guinness, and himself worked out, in a very small way, the great desire that they had that men and women going to the mission field might be so instructed as to be able to take care of their own health. In those days there was terrible mortality among British and American folk going to unhealthy climates. Personal experiences, testifying to the great practical value of the courses of instruction at Livingstone College, were given by the Rev. F. Hart of the Regions Beyond Missionary Union, Congo, and the Rev. *Geoffrey Holmes*, Church Missionary Society, Ruanda, *East Africa*. Mr. R. L. Barclay, the treasurer, spoke as to the financial position of the College; he appealed for £100 in order to close the financial year without an overdraft at the bank, and for a further £250 to £300 for urgent necessary repairs. The principal, Dr. Tom Jays, made a short statement with regard to the work of the College, and a vote of thanks to the chairman was accorded on the motion of Dr. L. E. Wigram.

A new series of conducted tours has been arranged in aid of King Edward's Hospital Fund for London. On June 18th there is to be a river trip to Tilbury Docks, including inspection of s.s. *Orontes*, with buffet lunch on board, by invitation of the Orient Steam Navigation Co., Ltd. The party will leave Westminster Pier at 9.30 a.m. On July 2nd a visit will be paid to Somerset House, where the party will meet in the quadrangle (off the Strand) at 4.30 p.m. The assistant Registrar-General, Mr. W. L. Rind, will receive the visitors and tell them something of the history of Somerset House. The last visit will be to the Air Port of London on July 14th, a private omnibus leaving Charing Cross underground station, Victoria Embankment, for Croydon at 2 p.m. As the number of each party is limited, application for tickets (price 25s. for the first tour, and 7s. 6d. for each of the others) should be made without delay to the secretary, King Edward's Hospital Fund, 7, Walbrook, E.C.4.

The twenty-fourth Voyage d'Etudes Médicales to the watering places of France will take place this year in the Western Pyrenees during the second and third week of September, under the leadership of Professors Paul Carnot and Maurice Villaret. The party will assemble on September 8th, at Capvern. The principal places to be visited are Bagnères-de-Bigorre, Le Cirque de Gavarnie, Cauterets, Lourdes, Argelès, Pau, St. Jean-de-Luz, Biarritz, Hossegor, Dax, Arcachon, Bordeaux (Faculty of Medicine and the hospitals), continuing along the coast to Royan, where the tour ends on September 20th. Further information can be obtained from Madame Juppé-Blaise, Federation of the Health Resorts of France, Tavistock House (North), Tavistock Square, W.C.1.

The issue of *La Medicina Ibera* for May 23rd contains an illustrated account of the first Hispano-Portuguese Congress of Obstetrics and Gynaecology, held at Madrid from April 28th to May 4th.

A general account, by Dr. P. Hefferman, of the trans-atlantic tuberculosis tour of 1930 has been published in the April issue of *Public Health*. It contains some comparative statistics of tuberculosis in England and Wales and Canada, a description of the work at Ninette Sanatorium, Manitoba, and a general evaluation of British and Canadian sanatorium methods. Dr. Heffernan also contributed to the January number of *Tubercle* some notes on pneumonoconiosis, in which he referred to silicosis in Canada, and mentioned the adoption by the Government of Ontario of the Bulmer air mask, which is thought by some to have gone far towards solving the problem of the dust risk in the mining industry.

The jubilee issue of the *Journal de Médecine de Paris*, the official organ of the Paris medical societies, contains the history of the journal, which was founded by Auguste Lutaud in 1880.

A bronze bust of the late Professor Clemens Pirquet was unveiled in the garden of the New General Hospital of Vienna on May 12th, when addresses were delivered by Professors Argt, Hamburger, and Noeggerath, and Miss Harriette Chick of the Lister Institute.

Dr. H. I. Daggett, on the occasion of his retirement after over thirty-eight years' practice at Boroughbridge, Yorks, has been presented by his friends and patients with an inscribed wallet, containing a cheque for £161, as a mark of their esteem and appreciation of his services.

Professor Raffaele Bastianelli has been nominated director of the Institute for the Study and Treatment of Cancer at Rome.

According to the Japanese Red Cross the average duration of life in Japan is 42 years for men and 43 years for women, as compared with 55 and 59 years in England, and 50 and 53 years in the United States.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are *MUSEUM* 9861, 9862, 9863, and 9864 (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Medisecra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62350 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS

"Naturkultur"

"X. X. X." (London, W.C.) writes: One of my patients is anxious to try naturkultur. Can any of your readers tell me of any centres in Germany or elsewhere where this is practised under medical supervision?

Catarrh of Upper Respiratory Tract

"S. S." writes: Can any reader suggest a remedy for catarrh in a suffering colleague? The condition—chiefly laryngeal and tracheal, but sometimes also post-nasal—is such that life has become a burden. The sufferer has had pulmonary tuberculosis (arrested some years ago). The larynx appears normal. All the usual remedies have been tried in vain, and vaccines have only aggravated the condition.

Income Tax

Appointment : Qualification Expenses

"G. C." holds an appointment at an institution which has been taken over by a county authority. If he wishes to continue to hold the appointment after the expiration of the original three years' contract he will have to take an additional qualification. Can he deduct as a professional expense the amount of the examination fee?

*** We do not think so, though the circumstances are admittedly unusual. The fee is incurred in adding to his qualifications for an indefinite future period, and would probably be regarded by the courts as capital outlay. In Simpson *v.* Tate, Rowlatt, J., distinguished between the expense of qualifying for an office and the (allowable) expense of performing it, and in that case even the cost of annual subscriptions was refused.

Changes in Partnership : Cash Basis

"R" has been affected by the following partnership changes: M, R, and B were in partnership until September, 1929, when B died and F entered the firm. The practice was treated as continuing for income tax purposes. R is retiring on July 1st next, and X is coming in as a partner. The firm's accounts have been made up to December 31st, and in 1930 R received £321 from book debts of the old firm M, R, and B, and £1,047 (net after deduction of the usual expenses) from the new firm M, R, and F. The inspector of taxes claims that for 1931–32 R must pay tax on the £321 plus one-quarter of £1,047, leaving the new partner to pay on three-quarters of £1,047, in respect of the nine months from July, 1931, to April, 1932; further, that for 1932–33 and 1933–34 R will be liable to assessment on the amount of cash paid to him in respect of collected book debts.

*** We are in disagreement with the inspector's suggestion. It cannot be too strongly emphasized that the amount of the cash receipts is merely a convenient method of calculating the earnings of a practice for a year—admittedly liable to variation from the amount of the true profit in any one year, but near enough in the long run if the practice is not substantially altering in volume. Having ascertained the "cash basis" profit of the whole practice for, say, 1930, that amount is deemed to be the "income" of the firm, as a firm, for the financial year commencing April 5th, 1931, and, for purposes of fixing the amount of tax to be borne by each partner individually, should be regarded as split up between the partners according to the arrangements in force for the taxation year. For instance, suppose that the profits of the practice, reckoned on a cash basis, for 1930 are £3,600, and that throughout the partners have taken one-third shares, then R will have to account, as for the financial year commencing April 5th, 1931, on one-quarter of one-third of £3,600—that is, on £300 only. The amount of cash paid to him out of the firm's account is not relevant. There is no real hardship on the new partner paying tax on unrealized earnings, or if there is, it is shared by every tradesman who finds his profits being locked up in stock and book debts.

LETTERS, NOTES, ETC.

Concurrent Herpes and Varicella

Dr. J. SPEARS (London, S.W.19) writes: On May 15th I was consulted by a female patient, aged 46, and found her to be suffering from a typical attack of herpes of the forehead and scalp on the left side, which had commenced on the previous day. It was accompanied by much pain. On May 18th I was called in to see her again on account of the pain, and found her affected also by an attack of varicella affecting the chest, arms, and back. The eruption came out in successive crops during the next three days. She thinks she had an attack of varicella in infancy. Probably it is rather rare to see the two eruptions simultaneously.

Warnings

"J. R. H." writes: The young man referred to by "A London Surgeon" in the *Journal* of June 6th (p. 1008) has, I regret to say, been extending his operations into the West of England. He has paid me two successful visits, and has traded upon my regard for his father, who served in the same unit in France with me. Unfortunately, also, he did not hesitate to appeal to my sympathy on the ground that his mother was away from home and unable to help him, having been called to the bedside of his younger brother at school, who was suffering from meningitis and seriously ill.

Dr. ROBERT HUTCHISON writes: I should like to warn doctors in the Harley Street neighbourhood against a seedy-looking, rat-faced individual who may call to make an appointment for a lady alleged to be living in Bournemouth, and who wishes to come up to London with a view to entering a nursing home. From my experience the appointment will not be kept, and some article of value will probably be missed after the caller has gone.

A Wrapping for Medicine Bottles

Medical practitioners who do their own dispensing, or keep dispensers, may be glad to know of a new device, which we are informed has already been well received. This is a neat paper bag or envelope, with gummed flap, to take 4, 6, or 8 ounce medicine bottles, and it appears to be a great improvement over the loose sheets of paper and sealing wax generally used. One of the main advantages of the new method is the speed with which bottles can be packed, for the whole operation takes only a fraction of the time required for wrapping in the old way. The prices range from 12s. 3d. to 17s. per 1,000, according to the size of the bag and the quantity ordered at one time. These bags are obtainable from Messrs. Charles Stevens and Son, 12–14, Great Central Street, Leicester, who will send samples to any medical man or dispenser on request.

Vacancies

Notifications of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 44, 45, 46, 47, 48, 49, 50, 51, 54, and 55 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 52 and 53.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 243.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

564 Agranulocytosis

W. DAMESHEK and M. INGALL (*Amer. Journ. Med. Sci.*, April, 1931, p. 502) report 9 cases of agranulocytosis (termed malignant neutropenia), of which 4 were typical of the angina agranulocytica of Schultz. Two were infantile cases, which is rare; two patients recovered. In one case arsphenamine injections were a probable etiological factor. Six patients were in the fourth decade of life. Though the disease is said to be more frequent in women, in this series the sexes were equally divided. The onset was usually with fever, chill, and sore throat; the high fever and marked prostration were at times out of all proportion to the very few physical signs. The outstanding laboratory finding was marked leucopenia; in severe cases the leucocytes may be so few as to be practically uncountable. As the disease progresses, not only does depression of the granulocytic tissue occur, but also marked depression of lymphoid and reticulo-endothelial tissue, so that the numbers of lymphocytes and monocytes become much reduced. In atypical cases without angina the differential diagnosis from blood dyscrasias may be difficult. Recoveries, if they occur, are spontaneous. Rational treatments are repeated transfusions, foreign protein therapy, and irradiation over the long bones. Numerous theories of the pathogenesis of the disease have been advanced; the present authors agree with Stocké that it is not a special disease but an abnormal reaction to sepsis. On the other hand, C. W. BALDRIDGE and R. J. NEEDLES (ibid., p. 533), from a study of four cases, conclude that the neutropenia was primary and the infection secondary. They emphasize the similarity between aplastic anaemia, aleukaemic leukaemia, and idiopathic neutropenia, and discuss the similarities which the latter condition bears to anaphylaxis and the Schwartzman reaction.

565 Choleriform Syndrome in Infantile Diphtheria

A. M. CROSS-LEBOURLIER (*Thèse de Paris*, 1931, No. 28) records eleven illustrative cases in infants aged from 17 days to 5 months, and states that diphtheria plays a very important part in the causation of the choleriform syndrome in infants which is characterized by sudden onset of choleriform diarrhoea, apyrexia, and rapid improvement after the injection of diphtheria antitoxin. Complete recovery, however, ensues only in cases due to the Klebs-Loeffler bacillus alone. The choleriform syndrome may be due to a mixed infection of the diphtheria bacillus and staphylococcus, either simultaneously or successively. In such cases, after improvement following diphtheria antitoxin, death follows from complications (probably due to the staphylococcus) such as suppuration or a recurrence of the choleriform syndrome. Congenital syphilis, evidence of which may be found during life or only at the necropsy, seems to predispose to the occurrence of the choleriform syndrome.

566 Herpes Zoster with Varicella

R. R. MCCORMICK (*Journ. Amer. Med. Assoc.*, March 7th, 1931, p. 766) records four cases of herpes zoster among persons in contact with one another during an epidemic of varicella. In the case of a man aged 23, a generalized vesicular eruption closely resembling varicella, and involving the skin of the entire body and the extremities, developed on the twelfth day of herpes zoster. Death ensued on the nineteenth day from general sepsis. No cases of varicella resulted from contact with this patient during the period of the generalized eruption. Post-mortem examination showed severe inflammatory and gangrenous lesions in all the layers of the skin, and a posterior poliomyelitis involving the posterior root ganglia, which were very friable and haemorrhagic, and the posterior half of the spinal cord.

567 Oxycephaly with other Malformations

H. SAETHRE (*Norsk Mag. f. Laegevid.*, April, 1931, p. 393) records a case of oxycephaly in a woman, aged 32, associated with a giant hairy naevus on the back, bone defects in the bodies of the cervical vertebrae and sacrum, and signs of increased cerebral pressure as shown by *x*-ray examination and lumbar puncture. Migraine with a retarded physical and mental development, as well as with a tendency to severe hallucinatory depression, was regarded by Saethre as connected directly or indirectly with the cranial deformity. The patient's mother and half-sister had oxycephaly, homologous syndactylism, and crooked fingers. The author has also seen a case of oxycephaly associated with malformation of the eyelids in a family where the father and three children (one daughter and two sons) had these deformities, while the mother was normal, as well as an isolated case of a woman in whom oxycephaly was associated with ptosis, syndactylism, and dystrophic hands and fingers. The combination of oxycephaly with other malformations is attributed to early embryonic disturbances. Similar malformations have been produced experimentally by treating the mouse embryo by *x* rays.

Surgery

568 Litholapaxy

J. R. CAULK (*Annals of Surgery*, April, 1931, p. 891) discusses the advantages and disadvantages of the suprapubic removal of stone from the bladder, as compared with litholapaxy. He considers that the latter is the ideal procedure for simple uncomplicated stones in the bladder, and that it may be employed even when a good number of stones are associated with other conditions. In 225 patients with vesical calculi the average age was 56.6 years; 197 cases occurred in males and 28 in females. The largest number of stones was found in patients between the ages of 60 and 70. About 25 per cent. of cases had an association of upper urinary calculus. Associated prostatic enlargement was present in 116 cases, and obstruction in some form or other in 55.8 per cent. of all cases. Out of the 196 operations performed, litholapaxy was employed in 112 cases, and vesical diverticulum, carcinoma of the bladder, and severe cystitis were not considered to be contraindications; many cases showing one or other of these complications were successfully treated by litholapaxy. The size of the stone, within reasonable limits, offers no difficulty to this form of treatment, and often the larger the stone the softer and easier it was to crush. In simple cases a local urethral anaesthetic is sufficient, but in the majority of cases caudal and twilight anaesthesia have been found to be the most satisfactory. Repeated litholapaxies, at intervals of about a week, have been more successful than a one-stage operation, and post-operative instillations of *B. bulgaricus* have given good results. Where repeated crushings are required an indwelling catheter is used, and careful attention given to the bladder. In 112 cases of litholapaxy, there was only one death and very few cases of post-operative complications. The average duration of stay in hospital was ten days, simple cases being dischargeable in two or three days. There was recurrence in 7.1 per cent. of cases.

569 Gastric and Duodenal Ulcer

M. WEINSTEIN and J. P. MCHUGH (*New York State Journ. Med.*, April 1st, 1931, p. 391) summarizes the records of 50 cases of acute ulcers of the stomach and duodenum admitted to the St. John's Long Island City Hospital during the past two and a half years. The youngest patient was aged 19 and the oldest 72; 88 per cent. of the patients gave a history of indigestion. Spinal

anaesthetic is considered by the authors to be the anaesthetic of choice; it was employed in ten of the cases, and only one death occurred, the patient being an emaciated old woman in whom perforation had ensued 22 hours before operation. In one instance, with recovery, the interval between perforation and operation was 29 hours. Simple closure of the perforation was adopted in 46 (92 per cent.) of the cases, and in the majority the omentum was sewn over the suture line for reinforcement. Gastro-enterostomy at the time of closure was performed in only one case, in which the suture of a large perforation considerably narrowed the duodenal lumen. Most patients remained free from a recurrence of symptoms, provided that a restricted diet was adhered to; early cure results from simple suture if the proper post-operative medical treatment is followed. In the event of the condition progressing a secondary gastro-enterostomy can be performed later. In the opinion of the authors gastric resection is too radical to be consistent with a low primary mortality.

570 Tenodesis in Paralysis of the High Adductors

TAVERNIER (*Lyon Chir.*, March–April, 1931, p. 177) records the case of a girl, aged 8, who suffered from serious loss of power in the left leg as the result of infantile paralysis. The thigh, owing to paralysis of the adductors, was in abduction and marked flexion; the position of the pelvis, assumed to overcome this abduction, had caused a high degree of scoliosis. Though the hip and knee were stabilized by preliminary operations, the muscular paralysis persisted. The age of the child prohibiting arthrodesis, and her growth necessitating constant change of apparatus, Tavernier decided to replace the paralysed great adductor by an inhibiting tendon, employing the tendon of a stillborn calf, which had been preserved in alcohol; such material had given excellent results in previous tendon restorations. The operation is described. The marked improvement which followed has lasted for four months. As a rule, the more stable bony grafts are preferred to tendinous ones owing to the progressive relaxation of the latter. However, Tavernier hopes that the improvement will be maintained, since the antagonist adductors were partially paralysed and had lost their normal power. Should the tendon lengthen more than the growing femur it can be shortened, and arthrodesis or arthrorisis performed when the age and ossification of the hip permit. The result in this case conforms to the conclusions of Nageotte as to the functional value of heterogeneous tendons.

Therapeutics

571 Antigangrene Serum in Scarlet Fever

A. STROË, D. HORTOPAN, and J. BAZGAN (*Rev. franç. de pédiat.*, 1931, No. 1, p. 23) state that since the war scarlet fever has been endemic in Bucarest, more than 1,500 cases having been admitted annually to the Children's Hospital. The increasing severity of the disease is shown by the fact that, whereas up to September, 1929, necrotic angina occurred in only about 2 per cent. of the cases, during last year its frequency had been as high as 7 per cent. Local treatment was not only useless, but might even prove dangerous, owing to its liability to aggravate the lesions and to spread the infection to the Eustachian tube and middle ear. The Dicks' scarlatinal antitoxin also proved inefficacious. Owing to the success obtained by injection of antigangrene serum in a case in which the bacteriological examination of cervical adenitis accompanied by gaseous oedema showed the presence of *B. perfringens*, the authors were encouraged to make use of antigangrene serum in cases of necrotic angina; they found that the results were more likely to be successful when the injections were given early and in large doses. The serum employed was polyvalent, and was composed of four different serums mixed in the following proportions: anti-*perfringens*, 40 per cent.; anti-*vibrion septique*, 30 per cent.; anti-*oedematiens*, 20 per cent.; and anti-*histolyticum*, 10 per cent. Of 70 patients, 39 being seriously ill, treated by antigangrene serum, 61 recovered and 9 died—a result which may be regarded as remarkably favourable in view of the fact that the usual mortality of severe necrotic angina is 80 per cent. Records are given of 15 illustrative cases in children aged from 2 to 15 years.

572 Sanocrysin in Pulmonary Tuberculosis

STUB-CHRISTENSEN (*Ugeskrift for Laeger*, April 2nd, 1931, p. 353) reports from the Silkeborg Sanatorium in Denmark observations on 438 cases of pulmonary tuberculosis in which treatment with sanocrysin had been completed by April, 1930. In 54 of these cases this treatment had been supplemented by other measures such as artificial pneumothorax. In the remaining 384 cases the only supplement to the injections of sanocrysin was ordinary sanatorium treatment. The cases were classified according as they belonged to the first sanocrysin period, with as a rule large doses, or the second period, with comparatively small doses. The results in the first period were not so good as in the second, the percentage of patients becoming sputum-negative being 55 as compared with 70 in the second period. Stub-Christensen does not trace this improvement in the percentage of successful results unreservedly to the reduction in dosage; he is more inclined to associate this improvement with a more discriminating selection of patients for this treatment in the second period. In the first period albuminuria occurred in 84 per cent., in the second period in only 13 per cent. Intestinal complications were reduced from 43 to 3 per cent., and the incidence of a rash from 39 to 10 per cent. The class of case found to be most suitable for sanocrysin treatment was the early case without cavity formation. Next, in order of their suitability, came early cases with cavities, mixed cases, and fibro-cavernous cases. There were twelve deaths among the 438 patients, and in two cases the sanocrysin was certainly responsible. The dosage in the earlier period usually began with 0.25 to 0.5 gram, succeeding doses of 1 gram, at intervals of three to five days, being injected until a total of 5 to 7 grams had been given. In the second period the initial dosage was 0.05 to 0.1 gram. The amount was then gradually increased to a final dose of 0.5 gram, and, in the last 75 cases, only to 0.3 gram. No injection was repeated till any reaction it might have caused had passed off. Three clear days were allowed between the first and second injections if the former had caused no reaction, and four clear days between the subsequent injections. The total dosage in most of the cases in the second period was 4 to 5 grams.

573 The General Therapeutic Value of Ergotamine

Besides the action of ergotamine and related substances on the uterus, an effect is produced on various parts of the sympathetic nervous system, and particularly a depressing or paralysing influence on the motor elements of that system which are stimulated by adrenaline. J. B. YOUMANS, W. H. TRIMBLE, and HELEN FRANK (*Arch. Int. Med.*, April, 1931, p. 612) describe a series of experimental and clinical studies devised to determine the action of ergotamine on the basal metabolism, circulation, and blood sugar content of normal persons, and of patients suffering from thyrotoxicosis. They report that in single subcutaneous doses of 0.5 mg. ergotamine had no significant effect on the basal metabolic rate or the fasting blood sugar level of normal human subjects, but the pulse rate was slowed and the diastolic pressure was slightly, but definitely, raised. The administration of 1 mg. by mouth, three times daily, for several days, also failed to modify the basal metabolic rate. In patients with thyrotoxicosis the action on the pulse rate and blood pressure was generally greater, and a rather higher individual variation was noted than in normal subjects. It is concluded that many of the reported instances of lowered heat production, slowing of the pulse rate, and alteration in the blood pressure following the administration of ergotamine should not be attributed to the action of this drug, but to failure to secure a true basal condition at the beginning of the experiment. The slowing of the pulse is not to be attributed to depression or paralysis of the accelerator nerves of the heart, but to a stimulating or sensitizing action on the vagus.

Ophthalmology

574 The Operative Treatment of Glaucoma

E. DE GRÓSZ (*Arch. of Ophthalmol.*, March, 1931, p. 327) reviews the history of glaucoma and its treatment. In attempting to compare the efficacy of the various operations, the issue is somewhat clouded by the nebulous state of the classification of the disease. The present author adopts Graefe's nomenclature: (1) inflammatory or congestive glaucoma (prodromal, acute, chronic, absolute, degenerative; (2) simple glaucoma; and (3) juvenile glaucoma. Discussing the various operations, de Grósz states that trephining gives good results in 83 per cent. of chronic congestive, and in 68 per cent. of absolute glaucoma. Cyclodialysis is beneficial in 48 per cent. of absolute (18 per cent. five years after); in 78 per cent. of chronic congestive (55 per cent. five years after); and in 88 per cent. of simple glaucoma (75 per cent. five years later). Iridosclerotomy proved effective in 94 per cent. of simple glaucoma (76 per cent. after some years). Cyclodialysis, causing the least disturbance, may be repeated several times, and if after several attempts the tension is not reduced trephining should be tried. Iridosclerectomy is only performed in simple cases which are controllable with pilocarpine. Iridectomy is employed for prodromal and acute congestive glaucoma, anterior sclerectomy for the juvenile form, and enucleation for degenerative cases. Though glaucoma has been kept in check for thirty-five years with myotics, operation is practically always required, and is still the best treatment.

575 Argyrosis of the Cornea

B. FRIEDMAN and A. RÖTTH (*Amer. Journ. Ophthalmol.*, December, 1930, p. 1050) report that in ten out of twelve cases of conjunctival argyrosis slit-lamp examination reveals the presence of the same condition in the cornea. In countries where trachoma is prevalent, argyrosis of the conjunctiva is so frequent that, perhaps for this reason, a concomitant argyrosis of the cornea is overlooked. This condition is most marked at the limbus, and diminishes towards the centre; it becomes a little more pronounced again at the upper limbus. The colour variation between the strongest and weakest cases may be brown, yellowish gold, yellowish green, greenish blue, and ultramarine. The pigment layer appears in most cases to be finely stippled; it lies at the posterior surface of the optical section, and probably between Descemet's membrane and the endothelium. In severe cases, in both cornea and lens, the precipitate between the cell layer and glass membrane seems to pile up from the cell layer towards the glass membrane. In some cases there is also argyrosis of the lens, which appears as a yellowish reflex from the anterior capsule, and as a diffuse yellowish colouring of the posterior cortex. In nearly all cases the scleral conjunctiva is tinged with gold. One patient, aged 41, had had bilateral trachoma for seven years. He had been using silver nitrate, two drops in each eye, almost daily. With the slit-lamp the conjunctiva of each eye showed argyrotic changes. The golden colour of the bulbar conjunctiva was visible by retro-illumination as a homogeneous tint. In the lower third of each cornea the deepest layers were stained deep gold, more pronouncedly near the limbus. The pigmentation was homogeneous. The anterior capsule of each lens threw a very marked golden reflex, more intense in the lower part of its periphery. No opacities were present. The iris, vitreous, and fundi were negative.

576 Ocular Hypertensive Conditions

Ocular hypertension secondary to arterial hypertension is usually attributed to glaucoma, but P. BAILLIART (*La Médicine*, January, 1931, p. 24) denies this, holding that there is only a very indirect relation between the two. In generalized hypertension there is usually no ocular increase; there may even be ocular hypotension. On the other hand, all glaucomatous subjects are not hypertensive. One cause of failing vision in glaucoma is an elevation of the tension of the ocular media above that of the retinal arteries, thus arresting their circulation; the extent of this arrest determines whether the ensuing blindness shall be partial or total. The lowest retinal arterial pressure is half that of the vitreous; if this equilibrium is disturbed the retina is imperilled. In acute glaucoma, measures which lower the pressure, such as venesection or brisk purgation, tend to aggravate this want of equilibrium. Bailliart believes that the ocular complications of arterial hypertension must be studied in the retina, and he discusses the production of retinal changes such as haemorrhages, papillary oedema and stasis, and venous thromboses. The appearance of retinal, as of cerebral, lesions is of grave prognosis in hypertension. The aspect of hypertensive retinitis is analogous to that of the albuminuric form; arterial hypertension is the basis of each, and the first symptom in both is a vaso-dilatation of the vessels of the optic nerve and retina. The former will assume the albuminuric type if renal insufficiency is present. However, the second can exist without, or be only slowly manifested by, signs of albuminuric retinitis. Therefore, in all cases of retinal hypertensive lesions, attention should be paid immediately to the kidney.

Obstetrics and Gynaecology

577 Lower Caesarean Section

V. B. GREEN-ARMYTAGE (*Indian Med. Gazette*, April, 1931, p. 184) commends the operation of Caesarean section of the lower uterine segment, since it preserves the life of the mother and child and is attended with a far lower mortality rate than is craniotomy. In 104 craniotomies in the Eden Hospital, Calcutta, the maternal mortality rate was 32.69 per cent., whereas in 75 cases of lower Caesarean section, clinically comparable, there were only eleven deaths (14.66 per cent.). The author uses de Lee's vertical incision through the lower uterine segment, and sometimes the transverse incision of Hendry. He remarks that this operation can be performed late in labour, and after the unsuccessful application of forceps, provided that the foetal heart sounds are audible and over 100 per minute. The incision heals better than in the classical Caesarean operation because it does not involve a contractile portion of the uterus. It is fully covered over by the peritoneum, which is an important barrier against infection, and the catgut stitches need not be pulled tightly, because they are only used for the approximation of the wound edges, and not for haemostasis, as in the classical incision. There is very little post-operative haemorrhage and no shock, the whole procedure lasting less than half an hour. There is hardly any risk of secondary rupture of the scar—a sharp contrast with the usual 4 per cent. incidence after the classical operation. In many cases, when the liquor amnii was decomposing, it was possible to drain successfully the operation area with a tube introduced subrapubically into each lateral sulcus of the lower part of the abdomen. The patients do not suffer from the distension, vomiting, and exhaustion which so frequently follow the classical operation. According to the author the maternal mortality with this operation in Chicago has fallen below 2 per cent., and he believes that his own statistics will improve when better conditions are established for the patients as regards early treatment of the labours on hygienic lines and the prevention of any septic infection.

578 L. E. PHANEUF (*Amer. Journ. Obstet. and Gynecol.*, April, 1931, p. 498) states that cervical Caesarean section in America is gradually replacing the classical forur. He reports an investigation of 418 cervical sections, of which in 198 the incision was transverse, in 160 longitudinal, in 58 transperitoneal, and in 2 extraperitoneal. He agrees that this operation provides protection against septic peritonitis, better healing of the incision, and an easier convalescence. The uncorrected maternal mortality in his series was 5 per cent., and the best maternal mortality statistics were obtained in the 198 consecutive transverse sections, where it was 3 per cent.

Pulmonary embolism was responsible for 1.19 per cent. of the deaths. This complication is frequently associated with any form of Caesarean section, and has to be borne in mind when an abdominal delivery is contemplated. The cervical procedure is easily repeated, if required; the highest number performed on one woman was six.

579 Ovarian Cancer

P. MOULONGUET and L. MALLET (*Bull. Soc. d'Obstét. et de Gynécol. de Paris*, March, 1931, p. 151) do not consider malignant ovarian tumours varieties of the same type of neoplasm; they maintain that these differ entirely from one another in their histogenesis, clinical nature, and evolution. They are classified as follows: seminoma; folliculoma; malignant vegetating papilloma; endodermoid epithelioma; degenerated teratoma (often containing chorion-epithelioma); fuso-cellular sarcoma; lympho-sarcoma; carcinoma secondary to a Krükenberg tumour; and exceptional types, such as pavement-celled epithelioma and ganglioneuroma. Some of these (the seminoma, folliculoma, etc.) are radio-sensitive; others, as the vegetating papilloma, are radio-resistant; the results of irradiation in any case will depend, therefore, on the type of tumour. Five cases, with the results following radiotherapy in each, are recorded. These indicate that in certain types radiotherapy is most valuable, and should be employed; it must be commenced early, and be applied over all the parts capable of being invaded through the peritoneum or lymphatics. Patients tolerate these extensive irradiations very well, and no ill effects due to anaemia or massive resorption have been recorded. Metastases, whatever their seat or number, should be similarly treated. A. BÉCLÈRE (ibid., p. 160) cites further cases illustrating the efficacy of x rays in ovarian cancer. Among other conclusions he states that the rays employed should be very penetrating, highly filtered, and emitted at a great distance; also that the fractional method by doses at suitable intervals is preferable to intensive treatment by massive doses in a short time.

580 Anaesthetization of the Lumbo-aortic Plexus

E. ABUREL (*La Gynécol.*, March, 1931, p. 163) describes the technique of injection of the lumbo-aortic plexus with novocain or percaine. The plexus, lying on the front of the fifth lumbar vertebra near the aorta, is reached by insertion of a long needle half-way between the last rib and the iliac crest on the left. In spontaneous labours pain is much diminished in the abdomen, loins, and thighs, without being affected in the perineum and sacrum. In obstetrical operations the cervix is rendered insensible to dilatation, and the corpus uteri to intrauterine manœuvres. According to the same author (*Bull. Soc. d'Obstét. et de Gynécol. de Paris*, January, 1931, p. 35), this mode of local anaesthesia may be supplemented during the expulsive stage of labour by epidural injection, or by bilateral infiltration of the perineum from the coccyx to the external abdominal rings. Two cases are recorded (ibid., p. 34) of severe hyperemesis gravidarum which yielded to two anaesthetic injections of the lumbo-aortic plexus; the effect is ascribed to severance of the utero-gastric reflex path.

Pathology

581 The Mode of Action of Vitamin D

L. J. HARRIS and J. R. M. INNES (*Biochem. Journ.*, 1931, XXV, No. 1, p. 367) record experiments on rats undertaken to elucidate the mechanism of production of hypervitaminosis D. It is known that an excessive amount of irradiated ergosterol may lead to undue calcification in bones and arteries, and to an increased quantity of calcium in unstriated muscle. The present work indicates that vitamin D exerts a profound effect on the metabolism of calcium and phosphorus. The ingestion of abnormal quantities of vitamin D gives rise to an increased titre in the blood of calcium and phosphorus, with a tendency to deposition of calcium in certain sites. Vitamin D deficiency, on the other hand, such as occurs in rickets, leads to a fall in the calcium and phosphorus in the blood, and to a consequent failure in the normal degree of calcification of the bones. In hypervitaminosis D the increased calcium in the blood is derived both from the calcium in the food, owing to greater absorption from the gut, and from that in the bony stores; the relative importance of these two sources of supply is determined by the available calcium in the diet, and by the degree of vitamin D excess. To compensate for the increased blood calcium and phosphorus the kidney responds by an abnormal urinary excretion of these two substances. The authors believe that vitamin D can act independently of the parathyroid, for that hormone seems to raise the blood calcium solely by withdrawing it from the bones, and without increasing the net absorption from the gut.

582 The Causal Organisms of B. coli Pyuria

M. FRANK (*Arch. f. Kinderheilk.*, February 23rd, 1931, p. 254) has investigated 31 cases of pyuria in children, 26 being infants and 5 older children. Catheter specimens were collected and cultivated on media. The resulting colonies were tested as to fermentation with the customary sugars—hexose, saccharose, maltose, mannite, and lactose; in addition, rhaminose, dulcite, adonite, sorbite, inosite, and arabinose were used, and some glucosides. For further differentiation Frank used the salicin, æsculin, and phloridzin tests, and estimated the capacity for indol formation and haemolysis. Fifteen different types of *B. coli* were found. The most frequent was one which behaved like *B. neapolitanus;* the next was *B. coli communior*, then *B. coli commune*, and finally a type which differed from *B. neapolitanus* in not fermenting dulcite. The other types were found only in single cases. Swabs were then taken from the vagina of some healthy babies; on culture a number of *B. coli* groups were found, and on further testing they proved to be identical with those causing pyuria. A similar investigation of the genital mucous membrane in male infants showed only scanty *B. coli*; to this fact may be due the relative infrequency of *B. coli* pyuria in male children. In examining the faeces of children fed on different diets it was found that the *B. coli* strains which fermented sugar were most numerous where the diet was rich in starches, and less frequent where it was richer in fats. The strains appearing most often in pyuria were found also particularly common in the intestines of artificially fed infants, most of them being also present in the vagina and intestines of healthy children of the same age.

583 Etiology of Encephalitis in Childhood

H. KNAUER and P. A. JAENSCH (*Jahrb. f. Kinderheilk.*, February, 1931, p. 265) report that by inoculation of the cerebro-spinal fluid containing the virus of encephalitis on to the cornea of a rabbit by Grüter's method a slight reaction was produced resembling superficial keratitis punctata; it was only visible with a powerful corneal microscope and a slit-lamp. Serial investigations showed that the virus of encephalitis was much more frequently found in the cerebro-spinal fluid than had hitherto been supposed. Positive reactions were obtained in all the cases of encephalitis examined, including those following influenza, whooping-cough, measles, and vaccination. The virus can be found in the spinal cord in cases of chronic encephalitis many years after the onset, and even in patients who have recovered. That the substance is a living virus and not a toxin is shown by its successful passage through animals. The virus is extremely resistant to cold, and can survive for months in the ice chest. Healthy persons can harbour the virus without becoming ill themselves, but are able to infect others. Well-known organisms such as staphylococci, streptococci, influenza bacilli, meningococci, and tubercle bacilli and their toxins can never produce keratitis punctata in the rabbit's eye, and if these organisms are present at the same time as the virus of encephalitis they generally disappear in the course of the disease. Inoculation of the measles virus does not give rise to keratitis punctata. The conclusion therefore appears justified that in post-infective encephalitis the virus of true encephalitis is still the cause of the condition.

FINEST BRITISH PRODUCTS.

KEROL CAPSULES

FOR DEAFNESS

Doctors prefer "ARDENTE" because—

"ARDENTE" STETHOSCOPE.

Mr. R. H. Dent makes a Stethoscope specially for members of the medical profession suffering from deafness. Many are in use, and excellent results are reported on the latest, as evidenced by the interest shown at the last B.M.A. Meeting

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, thus relieving head noises, giving inconspicuous hearing.
4. It conveys sounds from varying ranges and angles.
5. It is entirely different, uncopyable, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf through various causes.
7. It is helpful for conversation, music, talkies, wireless, home, office, public work, and sports.

FREE HOME TESTS
arranged for Doctors and Patients.
Medical Prescriptions made up to the minutest detail.

MEDICAL REPORTS.

Commended by all leading medical journals.—Mr. Dent will be happy to send full particulars and reprints on request.

Telephones: Langham 1411-1412. Secretary: N. Rutherford Watson.

MEMBER'S STATEMENT:

—, *Wimpole Street, W.1.*

Dear Mr. Rutherford Watson,

I am much obliged for your cheque for £100 sent me in respect of one special debt you have recovered amongst others. I would like to take the opportunity of expressing my great satisfaction with what you have been able to do for me.

To judge by letters received accompanying remittances sent directly to me in response to your appeals, all has been done without the slightest offence and my pleasant relations with the clients remain unaltered.

The work of the B.M.P.S. should be particularly appreciated by those who, like myself, are subject to limitations in respect of recovery by judicial process.

Very truly yours,

———M.D., F.R.C.P.

THE TREATMENT OF **GOUT**

PISTANY

RADIO-ACTIVE MUD PACKS

PISTANY SPA REPRESENTATION, 38, Sackville Street, W.1. Tel. Regent 2638.

Pistany (Czechoslovakia) offers the most effective treatment for the cure of gout.

Special provision is made for the diet of gouty patients in the hotels.

In mild cases a few weeks suffice to relieve the condition but the need for prolonged intermittent treatment often makes a course with Pistany Mud Cubes or Compresses at home, under the patient's own doctor's supervision indispensable for a complete cure.

The method of application is safe and inexpensive for Pistany's sulphur Mud is inert and sterile of mineral content and keeps indefinitely.

Send for interesting Medical and Tourist literature.

ST. ANDREW'S HOSPITAL

FOR MENTAL DISORDERS,

NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or who wish to prevent recurrent attacks of mental trouble; temporary patients; and certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

THE COPPICE, NOTTINGHAM.

HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. BRITISH SPAS
ARE BEST

and membership of the British Spas Federation is a guarantee of efficiency

AT British Spas, treatment is only given (except in a few minor cases) upon medical prescription.

At British Spas the staffs are educated and properly trained and, in some cases, medically trained and medically certificated.

Equipment and administration are thoroughly up to date and scientific. Every new treatment is tested and reported upon before being adopted.

British Spas are also remarkably fortunate as regards situation, scenic beauty and pure air. These factors, combined with the social amenities of a home town, aid the cure considerably.

BATH Hot Springs (120° F.) Radio-active. Royal Baths extensions now open.

SWISS SPAS

BADEN.

On the main line Zürich-Basle and Zürich-Berne. The hot springs of Baden were already known to the Romans. 17 radio-active wells at a temperature of 118.4°F. They contain sulphur and sodium chloride. The baths are obtainable in the hotels themselves. Treatments: warm baths, shower baths, massage, electric baths, inhalation, drinking cure, diagnostic-therapeutic institute, mechanotherapy. Recommended for metabolic diseases, rheumatism, gout, sciatica, diseases of the muscles, bones, and joints, retarded convalescence after injuries and operations.
Season: April 1st to November 1st.
For information apply to: Spa Director, Baden, Switzerland.

LOÈCHE-LES-BAINS.

One hour by electric railway from Loèche (main station on the Simplon route). Mild alpine climate. The baths were already known to the Gauls and Romans. The radio-active springs contain chiefly sulphate of lime. Two swimming pools. Every hotel has its own bathing installation. Treatments: warm baths, douche-massage, injections, air and sun baths. Recommended for: gout, rheumatism, sciatica, anaemia, post-operational conditions, convalescence, gynaecological diseases, circulatory disturbances, skin diseases.
Season: May to October.
For information apply to: Hotel Association, Loèche-les-Bains, Switzerland.

PASSUGG.

Near Chur. Situated on a picturesque plateau. Mild sub-alpine climate. Vast forests.
Treatments: The Ulricus spring (alcaline-muriatic), Belvedra spring (chalybeate), Fortunatus spring (alcaline-muriatic with iodine), Helen spring (mildly alcaline and acid), Theopnil spring. All varieties of accessory treatment. Dietetic treatment. Indications: Diseases of the digestive organs, diseases of the liver and bile ducts, kidney and bladder diseases, diseases of nutrition and metabolic diseases, especially diabetes, arterio-sclerosis, diseases of the blood and tropical diseases.
Season: May to October.
For information apply to: Spa Director, Passugg, Switzerland.

RHEINFELDEN.

10 miles from Basle, on the railway line Zürich-Basle. Famous for its vigorous brine, containing 31% salt, and for its "Kapuziner" spring, a highly diuretic calcium and boric acid well, and for its "Magdalena" spring, containing sulphates of calcium, sodium, and magnesium. 8 bath establishments with up-to-date installations. Treatments: brine baths, carbonic acid brine baths, drinking, mud-packs, "Mutterlauge" packs, inhalation, massage, gymnastics, all varieties of electric treatment, dietetic treatment. Recommended for: gout, rheumatism, arthritis, women's diseases, sterility, obesity, children's diseases, arterial hypertension, diseases of the heart, affections of muscles, bones, and joints, convalescence.
Any information and detailed booklet gladly supplied by: Enquiry Office, Rheinfelden, Switzerland.

SCHINZNACH.

Railway connections: Basle-Brugg-Zürich, and Berne-Brugg-Zürich. The hot springs of Schinznach were in use in Roman times and belong to the strongest radio-active sulphur wells on the Continent. Newly equipped, comfortable baths and inhalation rooms. Treatments: baths, drinking, sulphur-mud and sulphur-water packs, irrigations, inhalatorium, massage, X-rays. Recommended for: gout, rheumatism, affections of bones and joints, non-tuberculous catarrhs of the air passages, arterio-sclerosis, diseases of the skin, diseases of women, children's diseases.
Season: May to October.
For information apply to: Spa Director, Schinznach Bad, Switzerland.

TARASP-SCHULS-VULPERA.

The chief spa of the Lower Engadine. Glauber salts wells. The advantage of this spa lies in the combination of the curative properties of the waters with the alpine air and sun.
10 mineral springs of various composition. Up-to-date equipment for drinking and baths, air and sun baths, swimming baths, Zander-hall, X-ray institute, diet. Recommended for: affections of the digestive organs, metabolic ailments, nervous troubles, affections of the organs of circulation, of the organs of respiration, of the genito-urinary system, malaria.
Information supplied by: General Manager, Kurhaus Tarasp.

The introduction of special dietary tables for diseases of the digestive organs and the kidneys, as well as for diabetes, permits the physician to treat to the fullest extent each patient individually.

For information and the booklet "Swiss Spas and their Mineral Springs" (sent gratis), please apply to the Office of the Swiss Federal Railways, 11b, Regent Street, London, S.W.1.

ITALIAN HEALTH RESORTS

IN SUMMER AND AUTUMN. The greater part of Italy is more pleasant in Summer than at any other Season of the year. There are HUNDREDS of DELIGHTFUL ALPINE, DOLOMITE, LAKE and SEA-SIDE RESORTS.

E. W. OSBORN, Secretary.

Swansea General and Eye HOSPITAL. (316 Beds.)

HOUSE PHYSICIAN wanted, gentleman, single. Salary £150 per annum, with board, residence, and laundry. Duties to commence June 17th.

Applications, stating age, nationality, qualifications, and experience, together with copies of three recent testimonials, to be forwarded to the undersigned.

O. C. HOWELLS,
Secretary-Superintendent.

County Council of Middlesex.

RESIDENT ASSISTANT MEDICAL OFFICERS—REDHILL HOSPITAL, EDGWARE, and PARK ROYAL HOSPITAL, WILLESDEN.

The County Council invite applications for the positions of Resident Assistant Medical Officers at the Redhill Hospital, Edgware, and Park Royal Hospital, Willesden.

Candidates must be registered Medical Practitioners who have held resident appointments in a General Hospital. The officers appointed *will work under the control of the Medical* Superintendents, and will devote their whole time to their official duties.

Salary in the case of each appointment is at the rate of £400 per annum, rising by annual increments of £50 to £600 per annum, together with board, lodging, and laundry.

The successful candidates will be required to pass such medical examination as the County Council may direct, and, unless subject to the Poor Law Officers Superannuation Act, 1896, to contribute to the County Council's Superannuation Fund. The appointments will be held *during the pleasure of the Council, and subject* to one month's notice on either side.

Applications, stating (1) age, (2) qualifications, and (3) *previous experience, together* with copies of not more than three recent testimonials, must be received by the undersigned not later than June 20th.

No special application forms are provided. Envelopes must be endorsed "Resident Assistant Medical Officer."

Canvassing, directly or indirectly, will be a disqualification.

N.B.—Redhill Hospital is a modern General Hospital with accommodation for some 200 acute cases, and a similar number of patients at the adjoining Redhill Institution suffering from chronic disease are under the care of the Medical Staff of the Hospital. Park Royal Hospital provides accommodation for over 600 *acute and chronic cases.*

ERNEST S. W. HART,
Clerk of the County Council.

Middlesex Guildhall, Westminster, S.W.1.
June 2nd, 1931.

City of Nottingham.

CITY INFIRMARY.

The Health Committee invite applications from duly qualified Medical Practitioners for *the post of FOURTH RESIDENT MEDICAL* OFFICER (male) at the above Infirmary. The Hospital contains 875 beds for the treatment of all classes of sick persons. It is a recognised Training School for Nurses, and is equipped with all modern requirements.

Candidates must have held the post of House *Physician and House Surgeon in a General Hospital*, and preference will be given to those having had experience in a Poor Law Institution. Experience in the administration of Anaesthetics is also desirable.

The salary will be £350 per annum, rising by annual increments of £25 to £450, with rations and furnished apartments. Quarters for married men are not available. The successful candidate will be required to contribute to the Corporation Superannuation Fund.

Forms of application, together with particulars of duties, may be had from the undersigned, *to whom applications, with copies of not more* than three recent testimonials, and endorsed "Medical Officer," should be forwarded not later than June 20th.

Guildhall, W. J. BOARD,
Nottingham. Town Clerk.
June 2nd, 1931.

The Welsh National School of MEDICINE.

LABORATORY ASSISTANT wanted for the Medical Unit Laboratories, to commence duties on October 1st. *Must be a smart, active* man, fully trained and experienced in all Bacteriological and Pathological methods and *modern Laboratory technique.* Wages £5 per week.

Applicants must state their age and give full particulars of their training and experience in the various branches of laboratory work.

Applications, accompanied by not more than four testimonials, should be sent on or before *June 22nd to D. BRYNMOR ANTHONY, University* Registry, Cathays Park, Cardiff.

Dorset County Council.

EDUCATION COMMITTEE.

APPOINTMENT OF SCHOOL DENTIST.

Fully qualified School Dentist required. Salary £450 per annum, rising to £600, *with* further discretionary merit advances to £650 per annum. Application form and terms of appointment may be obtained on receipt of *stamped addressed envelope, from Director of* Education, County Education Office, Dorchester, to whom the applications must be sent not later than June 23rd.

Surrey County Council.

ASSISTANT MEDICAL OFFICER.

Applications are invited for the appointment of an Assistant Medical Officer. Candidates must possess a qualification in Public Health, and have had experience in the Medical Inspection of School Children, Maternity and Child Welfare, and the treatment of Tuberculosis and Venereal Diseases. The officer appointed will be required to undertake such other public health duties as may be *allocated to him. He will be* on the staff of the County Medical Officer of Health, must reside in the County, and devote his whole time to the work. Salary £600 per *annum, rising by annual increments of £20 to* £700 per annum. Travelling expenses in accordance with the Council's scale will be *allowed.*

The appointment will be subject to the approval of the Ministry of Health, to the provisions of the Local Government and Other Officers Superannuation Act, 1922, and to the Standing Orders of the Council, which provide, inter alia, that appointments may be determined at any time by three months' notice.

Applications, stating age, qualifications, and experience, together with copies of three recent testimonials, should be made on the prescribed form and sent to the County Medical Officer of Health, County Hall, Kingston-upon-Thames, from whom copies of the application form may be obtained, and to whom any enquiries relating *to the appointment should be addressed.*

Last day of receipt of applications, Friday, June 19th. Canvassing, directly or indirectly, will disqualify.

County Hall, *DUDLEY AUKLAND,*
Kingston-upon-Thames. Clerk of the
May 27th, 1931. County Council.

City of Leeds.

GATEFORTH SANATORIUM.

Applications are invited from duly qualified and registered Medical *Practitioners (male) for* the post of RESIDENT MEDICAL OFFICER at the City of Leeds Sanatorium at Gateforth (*50 beds*). *Applicants should have had pre*vious Hospital and Sanatorium experience.

The successful candidate will be attached to *the staff of the Tuberculosis Sanatorium at* Killingbeck, and will work under the direction of the Medical Superintendent of that institution.

The salary will be *at the rate of £450 per* annum, rising by biennial increments of £25 to £550, together with board, residence, and laundry. The candidate appointed will be required to pass a medical examination and to contribute to the Superannuation Fund.

Schedule of duties and form of application *may be obtained from the Medical Officer of* Health, 12, Market Buildings, Vicar Lane, Leeds.

Applications, endorsed "*Tuberculosis Officer*," together with copies of three recent testimonials, should be delivered at the Town Clerk's Office, 26, *Great George Street*, Leeds, not later than 10 a.m. on Saturday, June 20th.

THOS. THORNTON,
Town Clerk.

County Borough of Middlesbrough.

MUNICIPAL HOSPITAL (273 Beds), and BROOMLANDS CHILDREN'S HOSPITAL (55 Beds).

Applications are invited for the post of a JUNIOR RESIDENT *MEDICAL OFFICER.* The appointment will be for six months, with a possible continuation for a second six months. Salary at the *rate of £160* per annum for the first six months, and £170 per annum for the second six months, with board, residence, and *laundry.*

The appointment affords good opportunities for gaining experience, as the Hospital is equipped for modern X-Ray, Electrical, Medical, and Operative treatment.

Applications, stating age and qualifications, together with copies of three recent testimonials, must be forwarded to the undersigned not later than June 20th.

PRESTON KITCHEN, Town Clerk.
Municipal Buildings, Middlesbrough.
June 8th, 1931.

Kent County Council.

Wanted, LOCUM TENENS, with Sanatorium or Hospital experience, for eight weeks' commencing July 6th, to act as Assistant Medical Officer at the County Sanatorium, Lenham. 165 beds.

Salary seven *guineas per week*, in addition to board, lodging, and washing.

Applications, stating age and experience, to be sent to the undersigned.

ALFRED GREENWOOD, M.D.,
County Medical Officer.

Sessions House, Maidstone.
June 8th, 1931.

ROYAL ARMY MEDICAL CORPS.

TWENTY-FIVE permanent COMMISSIONS in the ROYAL ARMY MEDICAL CORPS will be offered in July, 1931. Applications should reach the War Office not later than July 20th, 1931.

Candidates will be selected for Commissions without competitive examination, and will be required to present themselves in London for interview and medical examination towards the end of July. They must be under 28 years of age on August 1st, 1931, and registered under the Medical Acts.

Officers of the R.A.M.C. are liable to serve in any part of the world where British Troops are quartered.

Ample opportunities exist in the Army for clinical professional work, both Medical and Surgical, as well as for the study and practice of Hygiene, Pathology, and all the special branches.

The cost of Post-Graduate study, which is compulsory, is met from Army Funds.

Pay and Allowances.—From £488 to £2,000 a year according to rank and length of service.

Candidates who have held a full-time house appointment in a recognised civil hospital before appointment to a permanent Commission in the R.A.M.C. may, subject to certain conditions, be allowed to count the period of service in such an appointment, up to a maximum of 12 months, as Army service for promotion and increase of pay.

Gratuities on Retirement.—After 7 years' service £1,000.
„ 15 „ „ £2,800.
„ 18 „ „ £3,500.

Current rates of retired pay range from £364 10s. per annum normally earned by a Major after 20 years' service, to £920 per annum, the maximum for which a Major-General is eligible. The rates of pay and retired pay are subject to periodical variation consequent on fluctuation in the cost of living.

Outfit Grant.—An officer on joining receives £50 as outfit allowance.

Marriage Allowance.—Officers of 30 years of age and over who are married are entitled to draw special rates of allowances.

A Voluntary Widows' and Orphans' Fund exists for officers of the Corps.

A certain number of temporary Commissions will be offered at the same time under the same conditions as regards age and qualifications as those required of candidates for permanent Commissions.

All particulars may be obtained by application, in writing or personally, to the Under Secretary of State, The War Office (A.M.D.I.), Whitehall, London, S.W.1.

INDIAN MEDICAL SERVICE

Recruitment of European Officers.

Applications are invited from medical men for permanent commissions in H.M.'s Indian Medical Service. The terms offered include a gratuity of £1,000 on retirement after six years' service, or £2,500 after 12 years' service, together with free return passages, for those who no longer desire to remain in the Service. In other respects the terms will be as detailed below.

Candidates must be British subjects under 32 years of age at the time of application, and must be registered under the Medical Acts in force in Great Britain and Northern Ireland.

CAREERS.

The Indian Medical Service offers wide opportunities of medical experience, including clinical, preventive, specialist, and research work. At the beginning of his career an officer is employed on the military side, which has medical charge of the Indian Army. Promotion is on a time scale up to the rank of Lieutenant-Colonel, and by selection to the ranks of Colonel and Major-General. An officer may apply after one year's Indian service to have his name registered for transfer to the civil side, from which appointments are made to Civil Surgeoncies, which are established at the principal civil centres to provide for the medical needs of civil officials and for general medical administrative purposes; to specialist (for example, public health and bacteriological) services; to research posts; and to professorships at the Medical Schools.

NOTE.—It is not possible to state at present what, if any, prospects of employment on the civil side will be open to Indian Medical Service Officers under the proposed new constitution for India.

PAY.

The monthly rates of pay for European officers in the Service who have a "non-Asiatic" domicile are as follows:

Rank.	Service in Rank.	Basic Pay.	Overseas Pay.	Years of Total Service.
1	2	3	4	5
		Rs.	Rs.	
Lieut.	—	500	150	1st
			150	2nd
			150	3rd
Capt.	(i) During first 3 years' service as Captain	650	150	4th
			£15	5th
			£15	6th
	(ii) With more than 3 and less than 6 yrs.' service as Captain	750	£25	7th
			£25	8th
			£25	9th
	(iii) With more than 6 years' service as Captain	850	£25	10th
			£25	11th
			£30	12th
Major	(i) During first 3 years' service as Major	950		
	(ii) With more than 3 and less than 6 years' service as Major	1100		
	(iii) With more than 6 years' service as Major	1250		
Lieut. Col.	(i) Until completion of 23 years' total service	1500	£30	13th and over
	(ii) During 24th and 25th years' service	1600		
	(iii) After completion of 25 years' total service	1700		
	(iv) When selected for increased pay	1850		

EXTRAS.—In addition to the above rates various allowances are admissible for a large number of special appointments on both the military and the civil side which may be held by members of the Indian Medical Service. Special high rates of pay are also attached to the numerous administrative appointments open to officers in both branches of the Service.

ANTEDATES IN COMMISSION.

Any service rendered by an officer during the war as a medical or combatant officer, or in a position usually filled by an officer, may be counted as service for increments of pay, promotion retirement and retired pay, but not for gratuity.

One half of any service in the ranks during the war may be counted as service for retirement and retired pay only.

Candidates possessing certain higher medical qualifications may be granted an antedate of one year in their commissions. Past service in certain hospital appointments may also render candidates eligible for an antedate of one year. Persons holding or about to hold resident posts at recognized hospitals may be seconded in those posts for a period not exceeding one year. The maximum period of antedate, secondment, or antedate and secondment combined, admissible under this paragraph, is limited to one year.

OUTFIT ALLOWANCE.

Officers on appointment will receive an outfit allowance of £50.

PRIVATE PRACTICE.

With the exception of Administrative Officers, military or civil, and officers holding certain special appointments, officers are not debarred from taking private practice, so long as it does not interfere with their proper duties.

LEAVE.

Leave can be taken at reasonable intervals, and adequate rates of leave pay are provided. Extra leave (known as study leave), which may not exceed 12 months in all during an officer's service, may be granted to officers desirous of pursuing special courses of study of a post-graduate nature. During such leave, study allowance, at present fixed at the rate of 12s. a day in the United Kingdom, £1 a day on the Continent of Europe, and £1 10s. a day in the United States of America, is granted to an officer in addition to ordinary rates of leave pay.

PENSIONS.

The rates of pension are as follows:

	Per annum.
	£
After 17 years' service for pension	400
,, 18 ,, ,, ,, ...	430
,, 19 ,, ,, ,, ...	460
,, 20 ,, ,, ,, ...	500
,, 21 ,, ,, ,, ...	540
,, 22 ,, ,, ,, ...	580
,, 23 ,, ,, ,, ...	620
,, 24 ,, ,, ,, ...	660
,, 25 ,, ,, ,, ...	700
,, 26 ,, ,, ,, ...	750
,, 27 ,, ,, ,, ...	800

These rates are subject to alteration on account of a rise or fall in the cost of living as compared with the year 1919 to an extent not exceeding 20 per cent. in all, the revision being undertaken triennially. With effect from July 1st, 1930, a reduction of 5¼ per cent. has been made on this account from the amounts shown.

There are additional pensions ranging from £65 to £350 per annum for officers who have held administrative appointments.

PASSAGES.

An officer on appointment is provided with free passage to India. The wives and families of officers who are married prior to the date of the officers' embarkation on first appointment will also be provided with free passage to India, subject to the payment of messing charges.

Officers and their families are also eligible for passage concessions under which they are granted a certain number of return passages home at Government expense during their service.

INSTRUCTION PRIOR TO EMBARKATION.

Officers are required to undergo courses of instruction at the Royal Army Medical College and at Aldershot, lasting approximately six months, prior to their embarkation for India on first appointment.

Full details regarding these appointments and forms of application may be obtained from the Under-Secretary of State for India, Military Department, India Office, London, S.W.1. The Selection Committee will meet at the India Office early in July next, and the selected candidates will be required to join a course of instruction commencing early in August, prior to sailing for India early in 1932. Applications should be submitted as soon as possible.

The Board of Management invite applications from fully qualified Medical Women for the undermentioned appointments:

Two HOUSE SURGEONS. Each for a period of six months from August 1st.

Salary at the rate of £100 per annum, with board, residence, and laundry. Candidates are required to call on Members of the Hon. Medical Staff before Saturday, June 27th, by which date applications and copies of testimonials must reach the Secretary at the Hospital.

Oldham Royal Infirmary.

HOUSE PHYSICIAN and CASUALTY OFFICER required forthwith. Appointment tenable for a period of six months. Salary at the rate of £175 per annum, with board, residence, and laundry. Successful candidate will be required to assist the Honorary Pathologist, and will be eligible for re-appointment.

Applications to be submitted forthwith, together with copies of three recent testimonials, to the undersigned.

CHARLES D. DRAKE,
General Superintendent.

Manchester Ear Hospital, GROSVENOR SQUARE, ALL SAINTS'.

The Board invite applications for the post of NON-RESIDENT HOUSE SURGEON. 24 beds. Salary at the rate of £150 per annum, with partial board. Candidates must be duly qualified and registered. Applications, with copies of four recent testimonials, to be forwarded to Mr. REGINALD S. MILFORD (Hon. Secretary, Manchester Ear Hospital), c/o Mr. W. J. ELLAM, 33, Brazennose Street, Manchester.

Rotherham Hospital. (130 Beds.)

Wanted, CASUALTY HOUSE SURGEON (male), qualified. Salary £150, with board, residence, and laundry.

Applications, with copies of recent testimonials, to be sent to the Secretary, G. W. ROBERTS, 8, Moorgate Street, Rotherham.

Huntingdon County Hospital.

HOUSE SURGEON needed. Salary £120 per annum, and laundry. Testimonials, etc., to Dr. GROVE, County Hospital, Huntingdon.

Bristol General Hospital.

The Committee invites applications for the following appointments which become vacant on August 1st next:

Two HOUSE PHYSICIANS; Two HOUSE SURGEONS; RESIDENT OBSTETRIC OFFICER; HOUSE SURGEON to the Special Departments; and a CASUALTY HOUSE SURGEON.

The appointments will be for six months at salaries at the rate of £80 per annum and at the rate of £100 per annum for the Casualty House Surgeon, and, in the event of second appointments being held, at the rate of £100 per annum in each case, with board, residence, etc., provided in the Hospital.

Candidates must be registered under the Medical Acts and produce testimonials of good personal character and ability, and must have recent experience in the administration of Anæsthetics.

Forms of application, etc., to be obtained from the Secretary, must be returned completed with copies of testimonials, addressed to the undersigned, on or before Monday, July 6th, from whom further particulars may be obtained.

THOMAS W. GREGG, Secretary.

Manchester Royal Infirmary.

RESIDENT SURGICAL REGISTRAR TO OUT-PATIENTS.

The Board of Management of the Manchester Royal Infirmary invite applications for the above appointment, vacant on August 1st. Applicants (men only) must be registered and hold a Medical and Surgical qualification and have held a Hospital appointment. The appointment is for six months, renewable for further periods of six months, subject to the provisions of the By-laws as to notice, etc. Salary £150 per annum, with board, residence, and allowance for laundry.

Further particulars of the post may be obtained on application to the Chairman of the Medical Board.

Letters of application, with testimonials, to be sent in not later than June 24th.

By Order,

F. G. HAZELL, Gen. Supt. & Sec.

June 8th, 1931.

All Saints' Hospital (for Genito-Urinary Diseases).

In-patient Dept.: 91, Finchley Road, N.W.8. Out-Patient Dept. and Secretary's Office: 49, 55, Vauxhall Bridge Road, S.W.1.

HOUSE SURGEON (male) required on July 1st for period of three months as Junior House Surgeon (non-resident), followed, subject to the approval of the Board of Management, by a period of three months as Senior House Surgeon (resident). Salary will be at the rate of £150 per annum, with board and laundry during the resident period. The duties of the non-resident House Surgeon consist of attendance at the Out-patient Department every afternoon and three evenings weekly.

Applications, stating age, experience, and qualifications and enclosing copies of recent testimonials, should reach me not later than June 20th.

D. H. EADE, Secretary.

The Royal Hospital,

WOLVERHAMPTON.

(Incorporated under Charter.) (300 Beds.)

Owing to the sudden and lamented death of Mr. Anthony Blackstock, F.R.C.S.Eng., there is a vacancy on the Honorary Staff for a Fracture and Orthopædic SURGEON.

Applicants should possess special qualifications and experience in the treatment of fractures as well as orthopædic surgery. The Surgeon appointed will be expected to devote considerable time daily to his hospital work, and he will be paid a substantial annual honorarium for doing so. He will be at liberty to practise privately as an Orthopædic Surgeon, for which there is a good opening in the large and populous district served by the Hospital.

Further particulars may be obtained from the undersigned.

W. H. HARPER, House Governor.

Wolverhampton.

June, 1931.

West End Hospital for Nervous Diseases.

(In-patient Dept., Gloucester Gate, Regent's Park, N.W.1.

The Wandsworth Borough Council invite *TENDERS for the supply of the undermentioned* furniture and equipment for the Borough Maternity Home at Grove Road, Balham, as follows, viz.:

1. BEDDING, etc.
2. CROCKERY.
3. FURNITURE.
4. HARDWARE.
5. HOSPITAL EQUIPMENT.
6. LINEN.
7. STERILIZING APPARATUS.
8. WATERPROOF SHEETING.
9. MISCELLANEOUS ARTICLES, ELECTRIC TABLE LAMPS, TIMEPIECES, etc.

Schedules containing quantities of the articles required and forms of tender and contract may be obtained on payment of 1/- per schedule on application to the undersigned, and no tender will be entertained unless it is made upon one of such forms and delivered at the Council House, East Hill, Wandsworth, S.W.18, not later than 10 a.m. on Friday, June 19th.

Where possible all articles must be of British manufacture. Any goods of foreign manufacture must be *specified in the form of tender.*

Council House, D. A. NICHOLL,
Wandsworth, S.W.18. Town Clerk.
June 1st, 1931.

APPOINTMENTS.—Contd.

City and County of Bristol.

NORTHAM COLONY FOR MENTAL DEFECTIVES.

ENGINEER. Salary £300 per annum, non-resident. Board of Trade certificate (with motor endorsement), or similar qualification necessary.

Applicants for these posts must not be over 40 years of age.

Forms of application, with further particulars, can be obtained from and must be delivered to the undersigned at the address below not later than June 30th.

The Council House, JOSIAH GREEN,
Bristol. Town Clerk.

Derbyshire County Council.

LOCUM FOR SANATORIUM.

Applications are invited for the post of Locum Resident Assistant Medical Officer at WALTON SANATORIUM, near CHESTERFIELD (130 beds), for a period of twelve weeks commencing June 29th. Salary at the rate of £350 per annum, with board, lodging, etc. Experience in Artificial Pneumothorax desirable.

Applications, together with copies of two recent testimonials, to be sent to the undersigned on or before June 20th.

New County Offices, W. M. *ASH*,
St. Mary's Gate, County Medical
Derby. Officer.
June 9th, 1931.

Royal South Hants and SOUTHAMPTON HOSPITAL, SOUTHAMPTON.

Applications are invited for the following resident appointments, which will fall vacant on June 30th next:

One HOUSE PHYSICIAN, £180 per annum. Six months' engagement.
One CASUALTY OFFICER, £180 per annum. Six months' engagement.
All with full board, lodging, and laundry.

Applications, together with not more than three testimonials, should be sent to the undersigned as soon as possible.

HY. TRUSSON, Secretary.

North Staffordshire Royal INFIRMARY, STOKE-ON-TRENT. (350 Beds.)

ASSISTANT HOUSE PHYSICIAN.

The Committee invite applications for the post of Assistant House Physician.

Salary at the rate of £125 per annum, with board, residence, and laundry. Previous Hospital experience necessary.

Applications, stating age, sex, and *experience*, accompanied by copies of two recent testimonials, to be submitted to the undersigned immediately.

By Order,
W. STEVENSON,
Secretary & House Governor.
June 8th, 1931.

Evelina Hospital for Children, Southwark, S.E.

Applications are invited for the post of CASUALTY AND OUT-PATIENT OFFICER (male) for six months from July 1st. Salary at the rate of £120 per annum, with board *and residence*. Hours of duty from 9.30 a.m. to 5.30 p.m. from Monday to Friday inclusive, Saturday until 2 p.m.; no Sunday duty.

Applications, stating age, experience, and qualifications, accompanied by copies of four testimonials, to be sent at once to the undersigned, *from whom rules and other particulars* can be obtained.

By Order of the Committee of Management,
W. H. SIDNELL,
June 8th 1931. Secretary-Supt.

Hertford County Hospital.

Applications are invited for the post of HOUSE SURGEON (male). Salary £200 per annum, with board, residence, and laundry. The appointment is for six months in the first instance.

Applications, with copies of three recent testimonials, should be sent to the undersigned.

PERCY G. BROOKS, Secretary.

The Hospital for Sick Children,
Great Ormond Street, London, W.C.1.

A PART-TIME JUNIOR CASUALTY OFFICER is required on July 9th, to assist in the Casualty Department, from 10 a.m. to 3 p.m. (Saturdays 10 a.m. to 1 p.m.), under the direction of the Casualty Officer.

The work of this officer includes a large number of Tonsillectomies and other minor operations.

Candidates must be registered Medical Practitioners, and have held a responsible Hospital appointment.

Gentlemen are invited to send in their applications, addressed to the Secretary, before 12 o'clock on Monday, June 29th, accompanied by copies of not more than three testimonials written specially for the purpose.

The appointment is made for six months, and is non-resident. Salary at the rate of £150 per annum, with luncheon.

All candidates must be in attendance to appear before the Joint Committee, if required, at their meeting on Wednesday, July 1st, at 5 p.m. precisely.

Forms of application and copies of the Rules may be obtained from the Secretary, at the Hospital.

By Order of the Board of Management,

June, 1931. JAMES MCKAY, Secretary.

West London Hospital,
Hammersmith, W.6. (234 Beds.)

Required, One HOUSE PHYSICIAN (General and Skin), one HOUSE SURGEON (General and Genito-Urinary), and one AURAL AND OPHTHALMIC HOUSE SURGEON for six months from July 1st next, subject to one month's notice on either side. Salary at the rate of £100 per annum, with board, lodgings, and laundry allowance.

Candidates must be registered under the Medical Act. Applications (which must be made on printed forms obtainable from me) must reach me not later than Thursday, June 18th. Selected candidates will be required to call upon such members of the Medical Staff as directed, to be in attendance at a meeting of the Medical Council on Friday, June 26th, at 4 p.m., and the House Committee meeting at 4.45 p.m. the same day, when the appointments will be made.

H. A. MADGE, Secretary.

Warwick County Mental
HOSPITAL, HATTON.

A vacancy has arisen for a SECOND ASSISTANT MEDICAL OFFICER. Candidates must have had considerable experience in the treatment of Acute Mental Disorders, and be able and willing to conduct Pathological investigations, etc.

The salary is £450 per annum, rising by £25 per annum to a maximum of £500, together with board, apartments, etc. In addition, £50 per annum is given for a qualification in Psychological Medicine.

There are no married quarters.

Applications, together with copies of testimonials, should be sent to the Medical Superintendent at the Hospital.

Knowle Mental Hospital,
FAREHAM, HANTS.

Required, a JUNIOR ASSISTANT MEDICAL OFFICER (male). Preference will be given to candidates who either have or are anxious to obtain a Diploma in Psychological Medicine.

The salary is £350 per annum, rising to £450 by yearly increments of £25, with board, lodging, washing, and attendance, valued at £150 per annum, and an extra £50 per annum will be paid to the selected candidate on obtaining the Diploma.

The appointment is subject to the provisions of the Asylums Officers Superannuation Act, 1909.

Applications, with copies of recent testimonials, should reach the Medical Superintendent by June 17th.

Lowestoft and North Suffolk
HOSPITAL.

JUNIOR HOUSE SURGEON (man or woman) required. Salary £120 per annum, with board, residence, and laundry. Applications, together with copies of three recent testimonials, to be sent to the Honorary Medical Superintendent.

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)
(FOUNDED 1880.)

Tele. Address: Triform, Wesdo—London.

12, Stratford Place,
Oxford Street, W.1.

Telephone: Mayfair {1782 1783

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION have every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence. Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUMTENENTS.

Assistants and Locumtenents can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The British Medical Bureau has its own staff of fully qualified Accountants wholly engaged on medical work—i.e., Investigation of Practices for purchasers, Income Tax, Auditing Books & Accounts, etc.

Good modern house, with special professional rooms. Nice garden. Garage. Freehold for sale, part on mortgage. Good sport and schools within reach. Premium 1½ years' purchase
30. NORTH OF ENGLAND.—GOOD TOWN.—A one-third share is offered in a very sound PRACTICE averaging about £5,000 p.a. Ingoing partner must be well qualified, not over 35, and interested in medicine. Suitable house available. Premium 2 years' purchase.
31. NEAR HEREFORDSHIRE BORDER.—A one-third to one-half share in a well-established good-class non-dispensing PRACTICE, producing about £1,800 p.a. Panel of over 500. Good house can be rented at £60 p.a. Sport of all kinds. Premium 1½ years' purchase, part by instalments. Welsh not necessary.
32. CHESHIRE.—COAST TOWN, within reach of Liverpool.—Well-established PRACTICE, averaging over £1,200 p.a., including panel of 720. Fees from 3/6. Mid. 2 to 5 gns. Double-fronted house, with 3 reception, 4 bedrooms, etc. Price for freehold £1,200, £800 on mortgage. Premium £1,100 for quick sale.

Full Schedule of Terms and Conditions will be forwarded on application.

Printed and published by the British Medical Association, at their Office, Tavistock Square, in the Parish of St. Pancras, in the County of London.

THE TUBERCULOSIS DANGER!

It has been stated in Parliament that *over two thousand children die every year through tuberculous milk.* How many children who survive grow up weaklings through the taint of bovine tuberculosis? This hardly bears thinking about. Cow & Gate Milk Food is guaranteed absolutely free from tuberculosis and other pathogenic organisms.

Read the following extract from the Presidential Address at the Royal Sanitary Institute Congress at Margate, it is of vital significance to the medical and nursing professions:

'The loss on the agricultural and veterinary side of 52,222 bovines during the three years 1926, 1927, 1928, slaughtered under the Tuberculosis Order of 1925, and at least twice that number not reported but otherwise disposed of, the estimate that 40 per cent. of the cows of our dairy herds producing milk for human consumption are tuberculous, are circumstances in themselves that demand immediate attention. But when to this is added the fact that in England 31.5 per cent. of tuberculosis in children up to 15 years is of bovine origin, and deaths from tuberculosis in children up to 5 years is 29.5 per cent. of bovine origin, that 57 per cent. of cervical adenitis in the same ages is of bovine origin, that 33 per cent. of bone and joint tuberculosis in children under 5 years and 24 per cent. in children from 5 to 10 years is of bovine origin, that in Scotland it is recorded that in certain hospitals in Edinburgh as much as 90.3 per cent. of cervical adenitis and 61.2 per cent. of bone and joint tuberculosis in children up to 12 years is of bovine origin, it is high time that this grave condition and this very serious menace to public health should be mended and ended. It is no credit to us as scientists and protectors of public health that such a state of affairs should be permitted to continue, or even to exist.'

-IS SAFE!

Another remark made at the meeting was as follows:

'It would be better to have no milk supplied at all than to feed children on diseased milk as is being done at present.'

MANUFACTURERS OF THE Cow & Gate Milk Food PREPARED BY COW & GATE LTD. GUILDFORD

"The best milk for babies, when natural feeding fails."

COW & GATE MILK FOOD

is prepared by our Special Improved Roller Process employing a short heat treatment which destroys all disease organisms but leaves the natural vitamins unimpaired. It is a basic milk food which can be modified by the profession as they desire to suit each and every case.

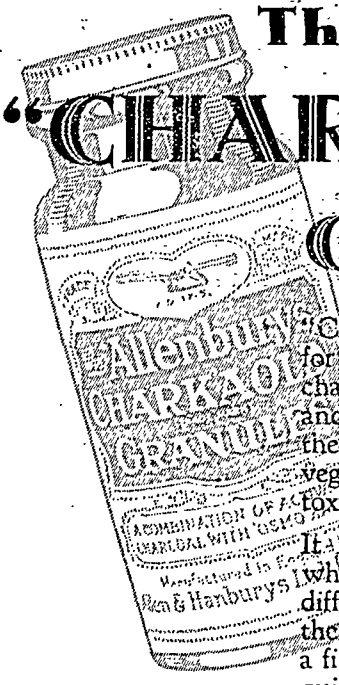
Dept. 20 COW & GATE LTD., GUILDFORD, SURREY B.M.J., June 13/31.



The "Allenburys"

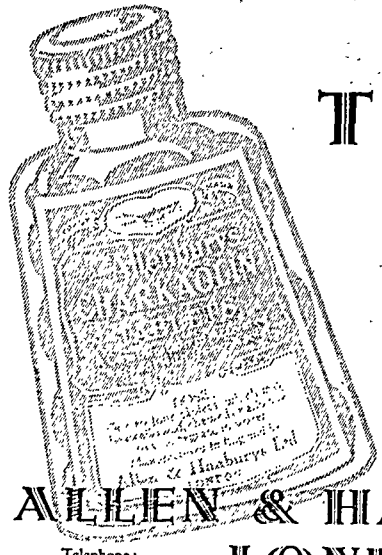
"CHARKAOLIN"

GRANULES

"Charkaolin" is a highly efficient agent for the treatment of intestinal infections characterized by abnormal fermentation and the formation of toxins. It combines the absorbent properties of highly activated vegetable charcoal with the well-known toxin-adsorbing qualities of "Osmo" Kaolin.

It is in the form of fine, clean granules which disintegrate rapidly in water and diffuse their ingredients evenly throughout the liquid. "Charkaolin" is tasteless, forms a fine suspension in water and is, therefore, quite easy to take.

In bottles at 2/6 each.



TABLETS

The "Allenburys" "Charkaolin" Tablets provide a convenient alternative method of administering "Charkaolin." Particularly suitable when travelling. Tasteless and disintegrate readily

In bottles:
40 tablets - 1/6
80 tablets - 2/6

THEELIN

Ovarian Follicular Hormone in Crystalline Form.

THEELIN is the name given to the ovarian follicular hormone first isolated in crystalline form by Dr. E. A. Doisy, Professor of Biochemistry at the University of St. Louis, who has entrusted Parke, Davis & Co. with its manufacture. Each batch is tested and approved by the Biochemical Laboratory of St. Louis University before being released for sale.

Theelin is a complex alcohol which does not contain nitrogen and is, therefore, not protein in nature. 1 milligramme of Theelin is equivalent to at least 3000 Doisy rat units.

Theelin is indicated in the treatment of functional amenorrhœa, in the subjective disturbance of either artificial or natural menopause, in delayed puberty, and in all those conditions in which less purified ovarian extracts have been used. It has the great advantage that it is free from certain side reactions which may be caused by the impurities present in varying amounts in the crude ovarian and follicular products.

Theelin is issued in aqueous solution in 1 c.c. ampoules, each c.c. representing 50 Doisy rat units. Supplied in boxes of 6 ampoules. Literature will be sent on request.

ISSUED WEEKLY] [COPYRIGHT] [REGISTERED AS A NEWSPAPER

EDWENIL: A POLYVALENT NATURAL ANTIBODY

FOR BACTERIAL INVASIONS
OF AN ENDOTOXIC NATURE

in FURUNCULOSIS

Whether there be a single boil or a multiplicity of furuncles, subcutaneous injections of Edwenil will produce a prompt response.

If treated in the early stages, the boil or furuncle disappears without coming to maturity. In more mature lesions the growths quickly come to a head, burst, and there follows a rapid recovery.

The time required for the complete resolving of even an extensive carbuncle is interestingly short.

Similar results have been obtained in long-standing cases of acne, where other forms of treatment, including X-Ray and Ultra-Violet Ray, had failed.

FOR PROMPT RESULTS IN COLDS AND HAY FEVER USE EDWENIL.

Obtainable in 25 and 12½ c.c. Bottles.

MADE ONLY IN THE LABORATORY OF

E. H. SPICER & CO., LTD.,

WATFORD, HERTS.

Telephones: WATFORD 5284-5285.

J. & A. CHURCHILL

SEVENTH EDITION. 2 Vols. 900 Illustrations (43 in Colour). 70s., postage 1s. 3d.

ROWLANDS & TURNER'S OPERATIONS OF SURGERY

"This is probably the most important modern textbook on Operative Surgery published by British Surgeons.
"The volumes are not only safe as a book of reference, but of the greatest value to the general surgeon. The searching and detailed revision which has been carried out in the last edition does great credit to the ability and industry of the authors."—PRACTITIONER.

FOURTEENTH EDITION. 64 Plates, 12 Coloured, and 103 Text-figures. 25s., postage 1s.

25s. **TAYLOR & POULTON'S PRACTICE OF MEDICINE** 25s.

Edited by E. P. POULTON, with the Assistance of C. P. SYMONDS, H. W. BARBER, and R. D. GILLESPIE.
"The cost of this valuable book has been actually reduced. The amount of work must have been enormous, and the result is certainly most successful."—BRITISH MEDICAL JOURNAL.

TWENTIETH EDITION. 10s. 6d., postage 5d.

HALE-WHITE'S MATERIA MEDICA

Revised by A. H. DOUTHWAITE, M.D., F.R.C.P., Assistant Physician, Guy's Hospital.

London: J. & A. Churchill, 40, Gloucester Place, Portman Square, W.1

NOW READY. 49th YEAR. With 70 Plain and Coloured Plates and many Text Illustrations. 20s. net. Postage 9d

MEDICAL ANNUAL, 1931

A YEAR-BOOK OF TREATMENT AND PRACTITIONER'S INDEX.

A Review of the Year's Progress in Medicine and Surgery, arranged in Alphabetical order.

EDITORS: CAREY F. COOMBS, M.D., F.R.C.P., and A. RENDLE SHORT, M.D., B.S., B.Sc., F.R.C.S.
IN CONJUNCTION WITH 29 WELL-KNOWN CONTRIBUTORS.

"There can be few medical publications in the English language that are so widely read as the 'Medical Annual.'"—BRIT. MED. JOURN.

Third Large Impression. Crown 8vo. 168 pp. 7s. 6d. net. Postage 4d.

THE ELEMENTS OF MEDICAL TREATMENT

By ROBERT HUTCHISON, M.D., F.R.C.P., *Physician to the London Hospital and the Hospital for Sick Children, Great Ormond Street.*
"The advice it contains is sound, free from fads, and not overburdened with useless details."—LANCET.

Bristol: JOHN WRIGHT & SONS Ltd. [Illustrated Catalogue free.] London: SIMPKIN MARSHALL Ltd.

Subscription in India and abroad Rupees 16 per annum. Post free. Payable in advance.

THE INDIAN

JOURNAL OF MEDICAL RESEARCH

Edited by THE DIRECTOR-GENERAL, INDIAN MEDICAL SERVICE, THE PUBLIC HEALTH COMMISSIONER WITH THE GOVERNMENT OF INDIA, *and* THE DIRECTOR, CENTRAL RESEARCH INSTITUTE, *in collaboration with* LEADING AUTHORITIES ON TROPICAL MEDICINE

The Indian Journal of Medical Research is published quarterly. Each number contains about 200 pages and is illustrated with Plates in Colour and Half-tone and with Diagrams and Charts, and is the only medium publishing the results of the best medical research work being carried on by leading scientific medical men in India and the East.

BRAIN, MIND, AND THE EXTERNAL SIGNS OF INTELLIGENCE

By BERNARD HOLLANDER, M.D.

The author, writing with the knowledge derived from a life-long study of the brain, makes a critical survey of modern research in this domain. He shows that the brain is primarily an organ of the instincts and emotions, only that part which is essentially characteristic of humanity being connected with the intellectual abilities which exclusively pertain to man. He makes valuable suggestions for the conquest of certain forms of insanity. *Profusely Illustrated.* 12s. 6d.

The Medical Profession when prescribing "Liquor Carbonis Detergens" SHOULD ADD THE WORD

Wright's

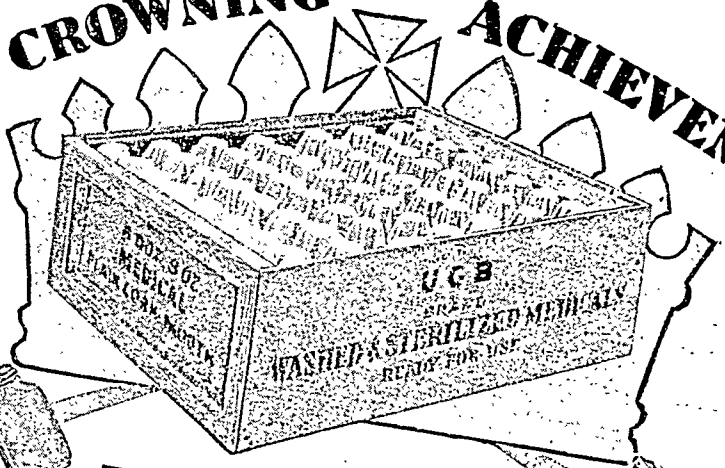
On receipt of your professional card, a package will be sent containing a sample of each of the following—

Wright's Coal Tar Soap.
Wright's Coal Tar Ointment.
Wright's Lysol.
Wright's Liquor Carbonis Detergens.

Although there is no secrecy as to the composition of Liquor Carbonis Detergens (it is described as "an alcoholic solution of coal tar"), the method of manufacture is unique. Imitations will be found to be produced by simple digestion, usually accompanied by some primitive, perfunctory, and inadequate stirring; whereas, in the case of the genuine product, the intimate contact required, for the complete extraction of all the soluble antiseptic constituents, is attained by a series of complicated processes, involving the use of highly specialized machinery.

WRIGHT, LAYMAN & UMNEY LTD., 66, Park Street, Southwark, S.E.1

THE CROWNING ACHIEVEMENT



U.G.B. MEDICAL BOTTLE *Service*

DURING the past ten years at tremendous expense, a very wide range of automatic machine mould equipment has been built up by the U.G.B. to cater for practically every bottle requirement of the Chemist and Dispenser. New and attractive shapes are now being added from time to time.

The Crowning Achievement was the introduction of the "Washed and Sterilised Ready-to-Use Package" which is daily growing in demand.

Only a small percentage of the actual cost of this service is passed on to the customer.

Supplied either for corks or complete with Rustless White Enamelled Screw Caps.

Once you have experienced the value and convenience of this U.G.B. Service you will use nothing else. Try it NOW and be prepared for the WINTER.

Obtainable from all leading Wholesalers.

A New Departure in Cigarette Manufacture

du Maurier

VIRGINIA

with the exclusive filter-tip

The Ministry of Health (Memorandum to Local Authorities, 8th Series). "No evidence has been adduced to support the contention that the mere inhalation and exhalation of tobacco smoke is of importance, although two possible causes of 'irritation' are *heat* and the *products of combustion.*"

The Claims of the Manufacturer

I. The filter-tip is selective in its action and while permitting the full passage of all the desirable constituents, shows a high capacity for retaining both the pyridine bases and non-volatile bodies, which undoubtedly form the principal source of throat irritation.

II. Unfiltered smoke is as dangerous as unfiltered water and as irritating as dust-laden air. The filter-tip effectively purifies tobacco smoke from harmful irritant and acrid substances which are inevitably formed when tobacco leaf, even of the finest quality, is burned.

III. By the introduction of the filter-tip the palate loses nothing, but the voice and throat gain immeasurably as the irritants are held in check without impairing the flavour or delicate character of the smoke. This is the central advantage to be gained from the filter-tip

IV. Cigarettes containing this filter-tip will be welcomed both by the medical profession and the public as a valuable means of preventing "smoker's cough" and other adverse effects on the pharynx, larynx or general health, traceable either directly or indirectly to the irritants and acrids in tobacco smoke.

V. They constitute the only safe form of smoking for those predisposed to, or suffering from, pharyngitis, laryngitis, or any form of bronchial or respiratory affection. They are invaluable in cases of gastric trouble due to tobacco tar.

A Selection from many Authoritative Endorsements

The aim of *this ingenious filter* is to trap the irritating pyridine derivatives and other non-volatile bodies, while permitting free passage of the agreeable volatile constituents of tobacco smoke.

The British Medical Journal, April 18th, 1931. p. 692.

A filter-tip must not only be efficient as a filter to irritating and noxious products, but must not affect the flavour . . . pyridine, the most offensive constituent of tobacco smoke, and other non-volatile irritant substances are retained by the ingenious filter-tip which is used in du Maurier cigarettes. From a personal trial we can testify to the *pleasant flavour and aroma* and to the *distinct lack of irritation* experienced in smoking these cigarettes.

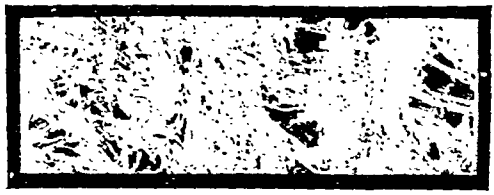
The Practitioner, May, 1931. p. 584.

We have tested these cigarettes and find them to be *cooler* and *less irritating* to the mucous membrane than ordinary cigarettes of good quality without the filter-tip.

The filter-tip . . . retains bodies which are generally held to be the principal cause of throat irritation. Additional advantages of the filter-tip comprise *protection of the lips, teeth and fingers from unsightly stain*, and prevention of fragments of tobacco from getting into the mouth.

The du Maurier cigarettes may be regarded in every way as satisfactory, and they constitute a distinct and hygienic advance in the marketing of cigarettes.

The Lancet, January 24th, 1931. p. 194.



Magnified view of cellulose fibre (contained in the filter-tip). BEFORE SMOKING.

Magnified view of cellulose fibre (contained in the filter-tip). AFTER SMOKING.

'du Maurier' Virginia Cigarettes at 20 for 1/-, 50 for 2/6, can be obtained from Peter Jackson, 217, Piccadilly, London, W.1, but we would prefer you to buy them from your tobacconist.

"VARIBAN"
Elastic Plaster BANDAGE

MADE from a specially woven selvedge material, possessing very elastic properties, evenly spread with an Antiseptic Zinc Oxide Paste. Self-adhesive, readily conforming to the shape of the limb, and when carefully applied forms an even surface dressing which will not crease or slip. Firm support. Easy to remove. Extensively used in many well-known hospitals for the treatment of VARICOSE ULCERS, VARICOSE VEINS, SURGICAL and ORTHOPAEDIC CASES, etc. Their application for treatment of Varicose Ulcers, etc., does not necessitate the patient lying-up; in fact, permits the continuance of light duties. Ensures rapid healing.

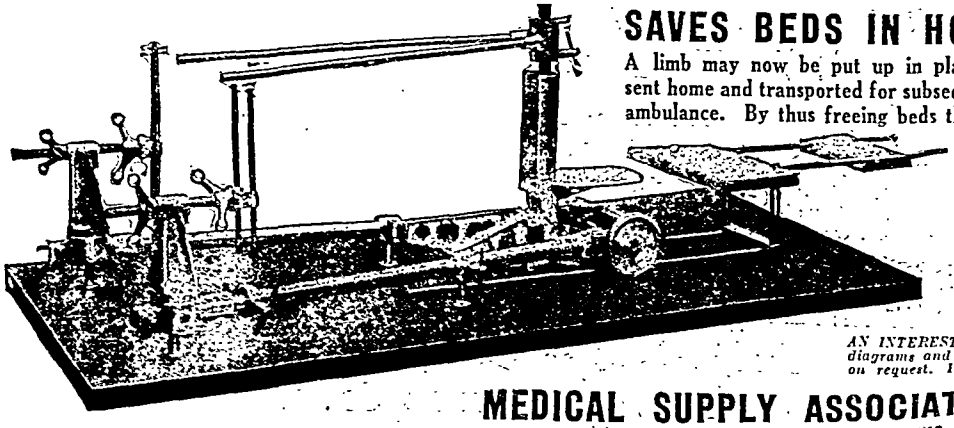
An IMPROVED and MODIFIED

Portable Traction Apparatus

An exceedingly efficient and convenient apparatus for putting up in plaster the lower limbs or trunk; also when applying bone plates or Parham and Martin's Bands to long bones of the lower extremity. Provides the more essential movements of expensive and bulky Orthopaedic tables at a fraction of the cost.

Quickly adaptable for the following positions:

Extension of whole lower limbs.
Movements about hip-joint:
Abduction to any degree—
Hyperextension—Flexion—
Internal and External Rotation.
Flexion of knee-joint.
Inversion and Eversion of foot.



SAVES BEDS IN HOSPITALS

A limb may now be put up in plaster, the patient sent home and transported for subsequent treatment by ambulance. By thus freeing beds this new apparatus saves its cost many times over.

Folds compactly for storage or transit in plywood case 35 in. × 15 in. × 11 in.

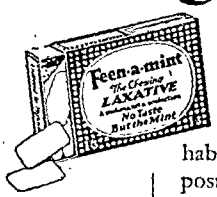
REGD. TRADE MARK

Feen-a-mint

The Chewing Laxative

Peristaltic Promotion



Feen-a-mint definitely promotes peristalsis without griping, and without irritation to the intestinal or reno-vesical mucosa. Its marked activity is due to the minute state of sub-division of its active principle (phenolphthalein) which is incorporated into a resinous gum base. Mastication assists further its division—thus a maximum therapeutic effect is exhibited.

Definite Defaecation

Feen-a-mint is valuable at all ages. It is a beneficial aid in 'difficult' and intractable cases—especially those due to habit-forming drugs, pregnancy, neglect and post-operative stasis. It has no secondary effects, and is not incompatible with any concurrent treatment. Pleasant to take, bland, yet certain in result, and non-habit-forming, Feen-a-mint is free from all objection to the patient.

Feen-a-mint is of marked assistance in

Modern diets often lack minerals

To-day, authorities are stressing the importance of the essential mineral salts. In addition to building sturdy bones, and blood rich in hemoglobin, these mineral elements aid metabolism and contribute to nervous stability.

Yet many modern diets cannot be depended upon to furnish the proper quota of minerals, and therefore *millions of people suffer from the effects of demineralization*. Cooking destroys a variable amount of the mineral value of foods—in some instances as high as 76 per cent.

To correct this loss and to remedy demineralization—with its attendant symptoms of nerve fag, neurasthenia, lowered vitality and loss of energy—a tonic rich in mineral salts is needed.

Compound Syrup of Hypophosphites "Fellows" contains the mineral salts of sodium, calcium, potassium, manganese, iron and phosphorus, together with the added metabolic stimulants—strychnine and quinine. Sixty years of clinical experience the world over testify to its value as a tonic.

Suggested dosage: A teaspoonful in half a glassful of water three or four times daily.

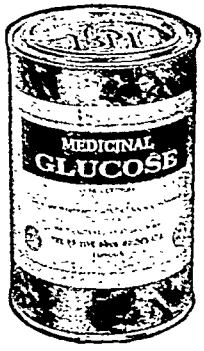
Fellows Medical Manufacturing Company, Inc. 26 Christopher St., New York City



For the Emotional Child

'. . . . it is now well established . . . . that not only cyclical vomiting and its varieties, anticipatory and otherwise, but night terrors, certain headaches often of migrainous type, some crises of collapse, some insomnias, certain cases of enuresis, and many cases of fatigue, belong to a group with the same metabolic fault behind them.'

It is suggested (*B.M.J.*, November 15th, 1930, p. 807) that the remarkable value of Glucose in correcting the above conditions is traceable to its action in building up the glycogen reserve of the liver, on which reserve in a child that is emotionally unstable there is presumably an abnormal demand.

Medicinal Glucose B.D.H. is a pure chemical substance designed for administration to emotional children in all those conditions, indicated above, which may be classified under the heading of acidosis.

THE ONLY LYSOL MADE TO THE ORIGINAL FORMULA, MARSHALL'S is relied upon by the greatest hospitals throughout the world. For your next case specify— MARSHALL'S LYSOL.
Sample free on request to members of the medical and nursing professions.
LYSOL LTD., Dept. K 19a, RAYNES PARK, S.W.20.

THIS
IS YOUR SAFEGUARD

The name MARSHALL'S on a Lysol bottle is an assurance that the doctor and nurse can place implicit confidence in its germicidal and antiseptic efficiency.

There are cheaper Lysols than MARSHALL'S, but the standard of quality set by the original product has never been equalled. There are preparations claimed to be "just as good," but MARSHALL'S LYSOL can be relied upon in every type of case as no other preparation on the market to-day. Its emollient action makes it safe to use for the most delicate purposes, and in the correct dilution it will not roughen the hands or corrode instruments.

The germicidal activity of MARSHALL'S Lysol is not impaired by the presence of organic matter, so it is efficient under all conditions.

INSULIN (BOOTS)

INSULIN (BOOTS) is prepared in the Laboratories of Boots Pure Drug Company Ltd., under Licence No. 19 (Therapeutic Substances Act, 1925) of the Ministry of Health.

It is made from selected ox pancreas which is subject to the strictest examination before use.

The company possesses specially equipped Analytical, Pharmacological and Bacteriological Laboratories in which all the tests required by the Therapeutic Substances Act are carried out.

Each batch of Insulin (Boots) is tested for potency against the International Standard Insulin and also for sterility—these tests being carried out both before and after filling into ampoules. A sample of each batch, together with a report on the potency and bacteriological tests made, are submitted to the British Medical Research Council whose certificate of correct strength and of sterility is obtained before the batch is issued.

A safe and simple antacid which is also a gentle laxative must necessarily be of great value to medical practitioners when administering to ladies and children and all who are constitutionally delicate.

May we, therefore, venture to remind you of

DINNEFORD'S PURE FLUID MAGNESIA

which has been extensively prescribed and used by the Medical Profession for a Century, and is still the best and safest means of administering Magnesia.

When prescribed for the nursery, too, Dinneford's Magnesia has always proved immensely useful as a corrective, and when mixed with infant's food it prevents many of the troubles which are due to acidity, flatulence, etc.

We are confident that you will find in Dinneford's Fluid Magnesia a reliable and safe solution which may be freely used for many ailments, and we would request your kind consideration of its use as occasion offers.

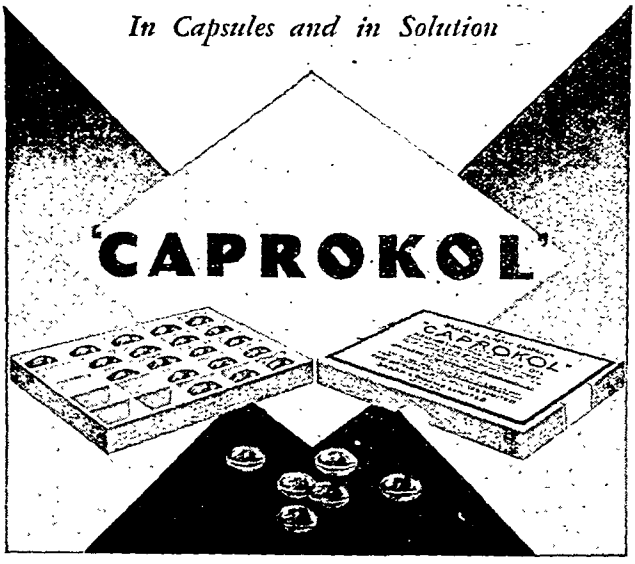
Dinneford's Pure Fluid Magnesia possesses antacid and laxative qualities which are incomparably better than those of any of the various preparations of Magnesia, in powder, now being introduced.

It cannot harm the most delicate constitution and is at all times a safe and effective laxative.

Manufactured in London for the past 100 years.

DINNEFORD & Co. LTD.

In Capsules and in Solution



In Genito-Urinary Infections

'Caprokol' is at once a soothing anodyne and a powerful bactericide. 'Caprokol' is administered orally, and is excreted by the kidneys practically unchanged; it produces a comforting analgesic action upon the mucosa of the urinary tract as well as a destructive effect upon the invading organisms.

These results of its administration, together with the fact that it does not stain, make 'Caprokol' the ideal antiseptic for use in genito-urinary infections.

ALOCOL

Colloidal Hydroxide of Aluminium

For Chronic Irritations of the Gastric Mucosa

WHEN alkaline therapy is indicated "Alocol" is the preferred form of treatment. Its advantages over the usual oxides and alkalis are manifest. Whilst the preparations in common use give momentary relief to painful symptoms they aggravate the morbid condition. Consequently such remedies are contraindicated, especially in stubborn, chronic cases.

The action of "Alocol" is superior in every way, because it does not merely confine itself to combating the symptoms of the trouble, but attacks the origin itself.

"Alocol" fixes the acid, not by neutralization, but by adsorption. It relieves pain, is slightly astringent, and limits the acid secretions. "Alocol" is always well borne; no harmful secondary action follows its administration, and its therapeutic effect is not diminished with prolonged use.

Complete chemical history of "Alocol," with convincing clinics reports and supply for trial, sent free to physicians on request.

A. WANDER, Ltd., Manufacturing Chemists,
184, Queen's Gate, London, S.W.7.
Works: KING'S LANGLEY, HERTFORDSHIRE.

M.230

A Distinct Advance Over Preparations of Acetyl-Salicylic Acid

Acetyl-salicylic acid possesses a notable disadvantage. Physicians have proved that it cannot be tolerated by patients suffering with a delicate stomach. Consequently, the value of this medicament in the wide field in which it is indicated is very seriously reduced.

"Alasil" completely overcomes this objection. By combining calcium acetyl-salicylate with "Alocol," unfavourable secondary action upon the stomach is prevented. This beneficial influence is undoubtedly due to the presence of "Alocol" (Colloidol Hydroxide of Aluminium), which preparation has brilliantly stood the test of practice in the treatment of hyperacidity and other ill conditions of the gastric tract. "Alasil" is therefore a triumph over acetyl-salicylic acid. It enables higher doses to be administered and maintains the patient's system under its influence for a greater length of time. Analgesic, Antipyretic, and Sedative, "Alasil" is indicated in all cases where acetyl-salicylic acid has been used heretofore.

A supply for clinical trial with full descriptive literature sent free on request.

184, Queen's Gate, London, S.W.7.

Alasil

M 233

HYPERPIESIS

HYPERPIESIS is described as "a malady in which blood pressure rises excessively, a malady having a course of its own and deserving the name of a disease."

A writer in *The Lancet* described cases of this condition, and ascribes its causation to toxic substances of the nature of which he is uncertain, but which he believes to be extrarenal in origin and to be distributed by the bloodstream.

It seems highly probable that these substances are the "pressor" substances, such as epinephrine, which are developed by putrefactive bacteria in the intestine. Assuming the truth of this likely hypothesis, the treatment in part should obviously consist in adequate intestinal disinfection

Certain compounds of the coal-tar series, having high germicidal value and little solubility in the alimentary tract, pre-eminently possess this disinfecting power and form the active constituents of Kerol, which may be given in a palatable form by means of keratin-coated capsules which ensure disinfection of the alimentary tract without deleterious effect.

For intestinal disinfection, use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.

(Dept. 153), 30/34, Mincing Lane, London, E.C.3.

For Patients with frail appetites

ONE of the great advantages of Ryvita Crispbread is that it is essentially palatable. The difficulty of getting a patient to eat is solved with Ryvita. Its crisp scrunchiness has an appeal only too often lacking with other articles of the dietary of corresponding value.

That Ryvita is a very valuable addition to the diet established beyond doubt. The richness of the rye grain in the salts of iron, phosphorus and calcium, its high vitamin B content, and its well-balanced protein-carbohydrates ratio, all make Ryvita of extreme benefit in maintaining bodily energy, while its retention of the natural roughage of the grain greatly assists in the process of elimination.

Yet at times its appetising nature alone would indicate Ryvita as an essential item of the sickroom diet.

We shall be very pleased to send a free carton, full analysis, and other particulars to all interested Members of the Profession.

"Eucortone"

(Cortical Extract of Suprarenal)

In the treatment of

Addison's Disease

Prepared by the method of Swingle and Pfiffner, it is highly successful in the treatment of Addison's Disease. It is believed to contain the cortical hormone in an active state, and to have an action in the crisis of the disease analogous to the action of Insulin in diabetic coma. It restores appetite, weight, strength, and feeling of well-being.

Dosage: About 10 to 20 c.cm. daily, intravenously or subcutaneously in divided doses.
In rubber capped bottles of 25 c.cm.

Suppurative Wounds

NUMEROUS applications have been used in the treatment of suppurative wounds, but recent investigations have disclosed the fact that the application of chemically pure glycerine is of definite value in diminishing the volume of exudate, inhibiting the spread of lymphangitis and reducing the swelling usually present about these wounds.

Antiphlogistine

dressings, due to their high glycerine content and to their antiseptic and osmotic properties, are of definite value in diminishing the volume of exudate and of reducing the swelling, while the changing of these dressings is not painful.

Kaylene

for the treatment of acute intestinal infections, ptomaine and other forms of food poisoning, and all diarrhoeal conditions. It acts by adsorption and is the true antidote to bacterial toxins and toxalbumins in contaminated food.

The action is speedy and certain.

Kaylene-ol

An emulsoid of the toxin adsorbent Kaylene combined with a highly viscous Liquid Paraffin. The latter counteracts the consolidating effect of the Kaylene. This preparation may be prescribed with confidence for those conditions in which toxaemia is associated with constipation. It actively prevents the absorption of toxins and completely puts an end to the fouling of the lymphatics and the blood.

Samples and "adsorption" literature obtainable on request to the Manufacturers:

KAYLENE LIMITED,

Waterloo Road (North Circular Road), Cricklewood, N.W.2

STANIFORM

Regd. BRAND. Trade Mark.

METHYL STANNIC IODIDE

OINTMENT Immediately stops the pain in all cases of burns, scalds, etc.

DUSTING POWDER For application where a greasy substance is contra-indicated.

LINIMENT Remarkably effective in treatment of Rheumatoid Arthritis.

LOTION A panacea for Mosquito and other insect bites. Most effective for all purposes where Tr. Iodine is employed. Does not stain the skin and there is no sting.

TABLETS Staniform being an organic compound is more easily assimilated than the Tin preparations at present in use.

Supplies may be obtained through the Wholesale Druggists, Druggists' Sundriesmen, or Dental Supply Companies.

What the Profession says

The following are some recent unsolicited testimonials reported to the Manufacturers by Medical Men:

"After using 'Staniform' Ointment in cases of Impétigo and other septic conditions of the skin, I was much impressed by the rapid response to treatment. Also herpes on the lip quickly disappeared after application of 'Staniform' Ointment."

"Festering wound on left heel—when first seen was about the size of a shilling, with a good deal of pus...Foot much swollen—dressed with 'Staniform' Ointment—healed splendidly in four days."

Similar testimony has been received from a large number of medical men when "Staniform" has been used for the treatment of Burns, Wounds, and Skin Ailments

STANIFORM is used in Leading Hospitals.

STANIFORM over a wide field of clinical experience has exhibited positive curative properties. Combining the well-known usefulness of Tin in staphylococcic infections with the powerful germicidal properties of Iodine, Staniform is indicated generally in local inflammations, inducing an immediate soothing effect with rapid healing.

STANIFORM LTD., CARNWATH ROAD, LONDON, S.W.6

BETTER MILK FOR BABIES

FACTS ABOUT
LACTOGEN

Carbohydrates

Compared with maternal milk the carbohydrate content of cows' milk is considerably deficient, but in Lactogen—by suitable modification—this deficiency has been rectified.

Unlike ordinary dried milks, in which the carbohydrate is in the same proportion as in the raw milk, LACTOGEN CONTAINS PRACTICALLY THE SAME AMOUNT OF CARBOHYDRATE AS WOULD BE FURNISHED BY HUMAN MILK.

Lactogen is neither a new nor untried product. First introduced in Australia, it has for many years enjoyed a large sale in overseas countries.

Lactogen is prepared in England by Nestlé's—famous for more than fifty years for the purity of their milk products—from the pure, fresh milk of specially selected herds, grazing on picked English farms.

VALUE OF POSTERIOR LOBE OF PITUITARY

Of all animal extracts, that of the posterior lobe of the pituitary gland offers to the medical profession an agent, at once definite in its effect and universal in its applicability.

Its employment is not empirical, but based on a definite knowledge of its effects. It is non-toxic and powerful, and offers to the obstetrician an invaluable aid to the conduct of his work, to the surgeon a useful haemostatic and general stimulant of involuntary muscle, and to the physician an effective means of raising blood pressure when required.

EVANS'

INFUNDIBULIN

This is the extract of the posterior lobe of pituitary prepared and standardised at Evans' Biological Institute so that 1 c.c. contains 10 International units. Great care is taken not only in its manufacture, but also regarding the suitability of the glass of the ampoules in which it is contained; it is therefore a remarkably stable solution.

Infundibulin is issued in ampoules of 0.5 c.c. and 1 c.c.

Brochure and sample may be had on application to:

HEWLETT'S
ORIGINAL PREPARATIONS.

ANTISEPTIC CREAM

(Cremor Antisepticus)

(HEWLETT'S)

A delicate antiseptic emollient healing Cream, instantly relieving the itching and burning sensation of the skin in cutaneous diseases. Its healing and soothing properties are widely recognized in the treatment of Wounds.

Price, in Collapsible Tubes 18/- per doz., or 5, 10, 22, 40, and 90-oz. Jars, 5/6 per lb.

GARGAR. FORMALIN CO.

(HEWLETT'S)

A most economical, efficient, and pleasant gargle and mouth wash, containing Formalin, Glyc. Acid Carbolic, Tinct. Pyrethri, etc., suitably flavoured. It is highly concentrated, one fluid drachm being sufficient for an eight ounce bottle.

PRICE 5/6 PER LB.

"Please supply us with a two pound bottle of Gargarisma Formalin Co. We have tried a small quantity and find our patients like it."—L.D.S.Eng.

HORMONIGEN

(HEWLETT'S)

Hormonigen Tablets (Hewlett's) contain the hormones of the thyroid, pituitary, ovary, and testes.

Useful in Neurasthenia and all asthenic conditions, obesity, chronic cardiac cases, aplasias of the pluriglandular system, and in anæmia. In Amenorrhœa, Dysmenorrhœa, and at the Menopause, Hormonigen is particularly effective, and even in chlorosis.

If there is high blood pressure, Hormonigen Sine Pituitary is indicated.

PRICE: HORMONIGEN, OR HORMONIGEN SINE PITUITARY,

3/3 PER 100; 30/- PER 1,000.

MIST. SENECIO CO.

(HEWLETT'S)

An elegant and effective combination of Senecio, Hydrastis, Pulsatilla, and aromatics which has proved very efficient in Amenorrhœa, Dysmenorrhœa, and Menorrhagia. The compound has a most beneficial effect in Dysmenorrhœa, relieving the pain and regulating the flow. In acting more particularly on the uterine nerves, it is of special value in the non-inflammatory form of Dysmenorrhœa. When anæmia and chlorosis are present, iron is an essential part of the treatment; but MIST. SENECIO CO. is useful as a general uterine and nervine tonic.

PRICE 12/6 PER LB.

In 5-oz., 10-oz., 22-oz., 40-oz., and 90-oz. Bottles.

UNG. IODERMIOL

An ointment of IODERMIOL that contains about 5 per cent. of Iodine, and is, therefore, stronger than the B.P. Ointment, whilst it does not harden or discolour the skin.

It has been found most useful for Enlarged Glands, Rheumatic and Gouty Affections, Lumbago, Sciatica, Swollen and Stiff Joints, Skin Diseases, Ringworm, etc. Ung. Iodermiol has also been used in cases of burns and scalds, and in the treatment of Chronic Lymphadenitis, Simple Bronchocele, and Atrophic Rhinitis, and in Purulent Ulcerative Otitis.

PRICE 6/- PER LB.

UNGUENTUM IODERMIOL et METHYL SALICYL. (HEWLETT'S)

Useful in the treatment of Enlarged Joints, Synovitis, Rheumatoid Affections, etc.

PRICE 7/6 PER LB.

VERONIGEN

(HEWLETT'S)

A liquid Preparation of this prompt and reliable HYPNOTIC has long been desired as a useful means of procuring sleep. When given in reasonable doses it is claimed that it does not produce any toxic symptoms whatever, and in ordinary cases of insomnia one fluid drachm of Veronigen (Hewlett's) is quite sufficient dose for an adult.

Dose for Adults.—One fluid drachm diluted, about one hour before going to bed.

For Nervous Sleeplessness in Children.—10 to 20 minims diluted.

VERONIGEN, 10/6 PER LB.

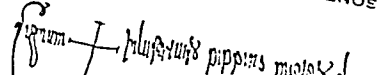
SIGNATURE OF PÉPIN LE BREF, THE FATHER OF CHARLEMAGNE.—To Pépin le Bref—or Pippin—is due much of the credit for the great things accomplished by his celebrated son. Pépin, as it were, mapped out the course which led to the success and splendour of the reign which played so important a part in the making of modern Europe. His shrewdness discovered the weak spots in the Frankish Empire. By vigorous campaigns he drove the Islamic Arabs beyond the Pyrenees. Aquitaine itself was seen by Pippin to be a menace to the peaceful development of the Empire and this province he added to the Frankish crown. A third danger was presented by the marauding Saxons,



upon whom he kept a strong hand and insisted that they should allow his missionaries (they were still Pagans) to live and work among them. Pippin the Short also took a momentous step in another direction: he formed a close alliance between the Church and the Empire of the Franks which led to a remarkable political development in Charlemagne's reign and influenced all Europe for centuries.

A British Medical Association Lecture

ON

SOME ANTE-NATAL PROBLEMS*

BY

SIR EWEN J. MACLEAN, M.D., D.Sc., F.R.C.P.

PROFESSOR OF OBSTETRICS AND GYNAECOLOGY, WELSH NATIONAL MEDICAL SCHOOL; VICE-PRESIDENT, BRITISH MEDICAL ASSOCIATION

A perusal of the now vast literature on ante-natal care, including tomes and textbooks, propaganda pamphlets and handbills, might lead the undiscerning to surmise that it was not until within recent years, or even months, that the general practitioner engaging in midwifery practice had become aware of the possible existence of, for example, contracted pelvis; of the significance of albuminuria in pregnancy, or of heart disease, or of tumour complications. Indeed, some of the less responsible of such publications, short, it is true, of actual delineation, would appear to imply a ludicrous picture of the general practitioner who, having casually accepted the responsibility of attendance, arrives all too late, bearing a small bag—usually faded black in exterior and indescribable in content—and is surprised and distressed to find the contracted pelvis case exhibiting the classical signs of ruptured uterus; or an albuminuria case in the throes of eclampsia; or the cardiac *in articulo mortis*. Let us extend to him, poor fellow, our heartfelt sympathy, for he has further to bear the reproachful demeanour of the ideal midwife and the fraternal greetings of the junior consultant, for whom, let us hasten to add, by way of giving a touch of colour to the unhappy scene, the enterprising local authority has provided a not unreasonable fee.

I have exaggerated this picture with the set purpose of saying that, whilst wise propaganda is undeniably essential to the much-needed wider submission of pregnant women to ante-natal examination, the kind of propaganda directed to undermining confidence in the general practitioner is as unwise as many or most of the allegations to that end are, emphatically, untrue. It is not thus that Ballantyne, perhaps the earliest and certainly one of the most distinguished of the pioneers in urging the necessity of ante-natal care in this country, initiated his mission, and it is assuredly not the manner in which he would have had it supported.

The truth is that as yet the sum total of knowledge concerning the causes of many of the ante-natal conditions which give us anxiety is limited, and that more effective lines of treatment can only be the product of further knowledge and of more experience in its application. This observation notably applies to the toxaemias of pregnancy, which afford, as a whole, a very complex biochemical problem, toward whose solution much intensive effort is now being directed. I was deeply interested to hear, for instance, in the course of a lecture recently delivered by Sir Frederick Gowland Hopkins, the distinguished President of the Royal Society, before the Cardiff Medical Society, that there is some hope of the identification of a certain vitamin which may be proved to play an important part in the toxaemias, and in the capacity of resistance to infection. But some of the day-to-day ante-natal problems lie much nearer to the surface than these biochemical delvings, hopeful and imperative though they be.

MINOR DEGREES OF PELVIC CONTRACTION

Let us take an illustrative case. A primigravida comes early in pregnancy to engage a medical man for her confinement. She presents none of the obvious signs of rickets, the urine is normal, and the general health good. But with the thumbs on the anterior superior spines and the first and second fingers of each hand on the widest parts of the iliac crests, he gains the impression that there is less than the usual one inch of difference between the intercristal and the interspinous diameters. There is, of course, nothing new in this preliminary thumb and finger estimate, but I constantly impress upon students, undergraduate and post-graduate, the importance and value of practising it whenever possible and on all kinds of cases, so that the individual examiner comes to establish a very helpful confidence in his initial impressions of the type of pelvis he has to deal with, and as to the further investigations which may be indicated.

In the case we are advancing for consideration he will check his impressions by the pelvimeter—preferably of the simpler type—and will find that the interspinous diameter is, let us say, 10½ inches, the intercristal 11 inches, and the external conjugate 7 inches instead of the normal 7½. The transverse of the outlet may be rather more than the usual 4 inches. The key diameter is, of course, the true conjugate, and in order to estimate it the diagonal conjugate must in due course be measured. In the early months of pregnancy, and especially in primigravidae, this is by no means an easy matter, even under an anaesthetic, and without it the necessary manipulation is difficult and painful. A simple vaginal examination at this stage, however, will serve to reveal the comparative roominess of the pelvic cavity and the absence of any considerable forward encroachment by the sacrum. Should the sacrum be easily felt in the course of such an examination it would signify a degree of contraction considerably in excess of what we are now contemplating in our illustrative case, which no doubt has been recognized, so far as we have gone, as one, probably, of simple flat pelvis.

Beyond reminding ourselves that about the fourth month the possibility of incarceration of the gravid uterus, due mainly to the degree of overhang of the promontory of the sacrum, has to be guarded against, let us leave our case to develop, so to speak, toward the later months, and consider for a moment pelvimetry.

Value of Pelvimetry

The measurement of the pelvis is one of the most important factors in ante-natal examination, and especially in that of primigravidae. How often it is that in taking the history of obstetrical and gynaecological cases the first labour is quoted as the beginning of the troubles when intervention became a matter of emergency instead of election, with its implied previous examination.

It is not my purpose to go into details of methods and measurements, but I am convinced that the value of pelvimetry to the individual practitioner as a guide to the management and treatment of a given case depends upon the sense of perspective and judgement which aggregated examinations have established in his own mind, confirmed or corrected in the only effective way, by the "follow through" of his cases into the natal and post-natal phases. I advocate strongly this continuity in the interests of the practitioner and of his patients. Any scheme which fails to provide for its observance where possible will by so much—and it is a great deal—come short of success. In many areas where ante-natal *clinics* exist, otherwise doing good work, this *virtual severance* from the subsequent phases has, admittedly, *minimized* their value for the patient and their *help to those in* charge of the labour and puerperium. *Poorly paid and* anxious though much of *midwifery practice may be, I* would urge general *practitioners, in view of the inevitable* developments in the *near future, to maintain a lively* interest in ante-natal work *in their own practices, and to*

* Delivered to the Leicester and Rutland Division of the British Medical Association, March 6th, 1931.

keep in touch with clinics where they exist. Many of these clinics are attractive in facilities for examination and are well staffed, but the great bulk of the women confined in this country have never been near them.

It is, I am sure, the experience of all here that the essentials of ante-natal examination are readily carried out in the patient's home or in the consulting room:

A simple form of pelvimeter—I personally use Baudelocque's, though there are others equally good—will give the principal external diameters; and of the internal measurements, the diagonal conjugate from promontory to subpubic angle, which by deducting half an inch gives the available true conjugate, is of dominant importance. As regards other internal measurements, the results obtained by the use of the more or less complicated pelvimeters are rarely of much practical value and may even be misleading. Such, anyhow, has been my experience, and where in asymmetrical pelves, for instance, the deformity is marked, the occasion for and the kind of intervention required are usually indicated by other and simpler means.

Management of Later Stages

To continue the running commentary on our primigravida with a minor degree of simple flat pelvis, now in the later months of pregnancy, say, the thirty-sixth week—a month from term. The preparatory redundancy and softening of the tissues has permitted a more accurate estimate of the diagonal conjugate and the deduction therefrom that the true conjugate is not less than 3½ inches—possibly 3¾ inches. Abdominal palpation portrays a first vertex with the head rather above the brim, and with an inclination towards the left iliac fossa. Such cases are far too often marked down in ante-natal clinics as likely to become transverse presentations, for which Caesarean section should be indicated, or, at all events, considered. The usual happening, however, is that with the onset of labour at term the faulty lie is corrected and the head becomes accommodated to the brim. It is worth remarking, also, that too much importance may be attached to the fact that in the minor degrees of this type of pelvis the head may not descend into the pelvis in the last two weeks, as it normally does in first pregnancies.

We have now, at the thirty-sixth week, to decide whether induction should be performed. The answer to that is concerned with the size of the child, and, in particular, whether the head is depressible into the brim with firm pressure. With a foetus of normal stage development it *should* be—the rather flattened pelvis notwithstanding. Assuming normality in all else than the pelvis as described, the prospect is that, given time and patience on the part of everyone concerned, delivery at term will be spontaneous, and that the prognosis for the mother and child is good—a plea for the natural forces of labour being given a fair chance.

I have purposely presented a marginal case with the focus of clinical interest on a form of pelvis which is not infrequently met with, and which has too often been regarded as, in itself, an indication for induction or even Caesarean delivery. It is an illustration, therefore, of how the beneficent purposes of ante-natal examination may be abused and lead to meddlesome midwifery.

ALBUMINURIA OF PREGNANCY

In some of the pamphlets, and even in some of the recognized textbooks, it is stated or implied that if this condition is discovered ante-natally in a woman who subsequently dies of eclampsia it is a disgrace to the practitioner or to the institution concerned; that, with all we now know of the toxaemias and their evil companion-conditions, the item eclampsia should be caused to disappear from the list of factors contributing to the total of maternal mortality. Now this is just exaggerated propaganda. It is a welcome fact that by careful observation and treatment a much larger proportion of our albuminuria cases do not so terminate, but, as I tried to show before, so long as our knowledge of the nature of the toxaemias remains so limited, eclampsias will still be with us. The contrasts and surprises they afford render them profoundly interesting.

A few weeks ago I had under my care a young primigravida who had been admitted to the Maternity Hospital in a profoundly comatose state, having had several eclamptic seizures before and during a long ambulance journey from the country. She was cyanosed, the temperature about 102° F., the pulse of wretched quality and almost uncountable; the urine scanty and coffee-coloured, and giving a practically solid albumin reaction, with other derivatives of acidosis. The blood pressure approached 200 mm. She delivered herself of a dead-born child some hours after admission. At intervals the eclamptic fits continued. So far as was possible routine treatment was given, including colon wash-outs and moderate doses of morphine. I demonstrated this case to the students as one with hopeless prognosis. In a few days, however, we met again at her bedside, and the clinical picture was a very different one. Some mental hebetude remained, but was rapidly clearing. The pulse, temperature, and blood pressure were much reduced. The urine was of fair quantity, and the albumin reaction much less marked. Thence onward recovery was uninterrupted.

In contrast to this was a previous case, another young primigravida sent in from the ante-natal clinic when about five months pregnant, with albuminuria—no previous history of scarlet fever or other illness likely to have caused nephritis. There was no oedema, no headache, no dimness of vision. Temperature and pulse were normal. The albumin reaction was moderate, and was the only abnormality detected in the urine; under low diet, aperients, and diuretics this cleared up, and the patient was allowed to return home and to report at the clinic. She was readmitted two months or so later with a recurrent albuminuria, and again responded, though not so completely, to similar treatment. In the course of a week or so adverse symptoms appeared, and developed in number and degree until she presented the typical picture of pre-eclamptic toxaemia. Induction was effected with no specially untoward incident; but, notwithstanding the employment of anti-eclamptic treatment and regimen in full measure, with skilled nursing, the dreaded seizures supervened and continued in increasingly rapid sequence until the patient died.

What may be the essential difference between cases, so similar clinically and so different in their outcome, we may hope that one day the biochemists will tell us.

HEART DISEASE AND PREGNANCY

The fact that normally slight dilatation and hypertrophy of the heart occur during pregnancy is sufficient indication that where the association exists with a damaged heart some anxiety must necessarily be felt. While it is happily true that the majority of the cases, with care, win through, there are others in which the closest observance of careful treatment is essential before, during, and after labour. The order of gravity of cardiac default associated with pregnancy is commonly accepted to be as follows: rheumatic myocarditis, aortic regurgitation, mitral stenosis, and mitral regurgitation. The most critical phases of test are the acme of labour pains; the profound circulatory adjustment called for on the delivery of the child, and the completion of the third stage; and the more steady strain of the early puerperium. The case I refer to under this heading especially illustrated the difficulty, so often experienced, of deciding as to the advisability of inducing labour.

The patient was a primigravida, aged 27, giving a history of having had chorea when she was 12 years old and pneumonia when 23. On admission she was four months

pregnant, and complained of breathlessness on exertion, such as walking upstairs, during the previous four weeks. She had unmistakable mitral stenosis, with a few extrasystoles, but no fibrillation—the pulse 120 and of indifferent volume and tension—no oedema, and no liver enlargement. She responded satisfactorily to treatment, which included complete rest, light diet, aperients, 10 minim doses of tinct. digitalis, sometimes combined with 5 grains of sodium bromide, and was allowed, after six weeks in hospital, to return home with strict injunctions as to rest and suitable regimen.

She returned to hospital in her thirty-fourth week. The general condition was fair—pulse 94, no auricular fibrillation; but there was some oedema of the legs, and she also complained of a recurrence of the breathlessness on even slight exertion. Under similar treatment, including 10 minims of tinct. digitalis every six hours, the oedema cleared up in a few days and, all things considered, her condition once more became satisfactory.

Although there was no indication for it from the pelvic side, I decided to induce labour mainly for two reasons: to take advantage of a favourable phase, and to avoid the possibility of a prolonged strenuous labour. Watson's medical method failing, as it so often does, bougies were introduced under general anaesthesia. The reaction was very unfavourable, and in the course of twenty-four to thirty-six hours most of the signs and symptoms of cardiac distress appeared —pulse 120, fibrillation, precordial pain, oedema, cyanosis, dyspnoea. But labour pains came on and were accelerated by small doses of pituitrin. Large doses of digitalis again controlled the pulse, reducing it to 80 a minute. The head being now well into the pelvis, forceps delivery under anaesthesia was effected, and was followed by a rather prolonged third stage, but with no undue haemorrhage. The 5 lb. infant survived, and the mother achieved a remarkable rally in three days, with a pulse of 92 and a sense of comparative well-being. A relapse followed, and again a still more marked recovery, only to be followed by a further relapse on all points, to which, on the eighth day, she succumbed.

The problem is, would this patient have had a better chance of pulling through if I had decided to allow her to go to term? In such a case it is, at best, a question of chances either way, but my impression is that the question should be answered in the affirmative.

TUMOURS COMPLICATING PREGNANCY

My final problem case is concerned with tumour conditions complicating pregnancy.

A farmer's wife, accustomed to the strenuous duties of her outdoor occupation, and pregnant for the first time at the age of 40, was sent to me by a country practitioner with the statement that the pregnancy was advanced to about the sixth month, and appeared to be complicated by a multinodulated fibroid condition of the uterus; that the patient and her husband were very anxious to have a living child; and that, if deemed to be indicated, they would agree to the performance of Caesarean section at term.

I concurred in the tentative diagnosis. There had been no menorrhagia before the onset of pregnancy, but that is not uncommon where the multinodular variety of fibroid is predominant. The abdomen was very large, and occupied by many irregularly shaped lumps. The patient had habitually enjoyed good health. Her main trouble had always been constipation, the bowels being copiously evacuated at weekly or longer intervals.

I agreed also to the line of treatment suggested, particularly as per vaginam one or two of the nodules could be felt in the pelvic cavity with the cervix partly raised above them, a condition which could effectively block the transit of the foetus. I explained, however, that it was possible that as the pregnancy advanced to the later months the enlarging uterus might pull these nodules upward out of the pelvis, even to the extent of rendering a Caesarean operation unnecessary. I had no further opportunity of checking the diagnosis because, although the patient promised to come later for another examination, she did not do so, and the next I heard of the case was over the telephone after midnight from the doctor, to the effect that labour was well on its course and that, moreover, the patient was already on her way by transport to the nursing home. I arrived at the home just in time to supervise the completion of a normal breech delivery. As was to be expected the abdominal masses were post-natally much less in evidence.

The puerperium was normal, excepting that when on the third day the action of the bowels had, in addition to aperients, to be solicited by enemata, the nurse reported that the copious result per anum was supplemented by some faecal matter coming per vaginam. Much concerned, I made a most careful examination, and could find no trace of vaginal fistula communicating with the bowel. With that temptation to complacency to which clinicians sometimes yield, I expressed the view that the nurse must have been mistaken. She, being a competent and well-trained person, said no more, but no doubt held to her opinion, although the phenomenon did not again occur.

Some months later the patient came to see me complaining that the abdominal lumps were causing her much discomfort, and that she wanted them removed. Examination showed that though altered in shape and dimensions they were still present, and in due course I performed a laparotomy, and the nature of the problem was revealed. An enormous megacolon extended almost from flank to flank and from the pelvis to well above the level of the umbilicus. A well-involuted uterus with appendages complete was *in situ*, and most of the small intestines were packed away towards the left hypochondrium. The "tumours" were partly consolidated scybala and stercoliths—one of the latter was so large and hard that I deemed it proper to remove it by excision through the colonic wall—an analogue of Caesarean section to save the poor lady the pangs of its delivery *per vias naturales*.

A very interesting case; and though it may only be in the form of a postscript to its record, I think it is due to that nurse to say that her observation was surely correct, because the patient on further inquiry recalled that one of her early childish troubles was that fluid faecal matter in small quantities occasionally came per vaginam. A rare complication of this variety of megacolon is the persistence of a communication between the bowel and the cervical canal. The conditions obtaining in the early days of the puerperium would tend to increase its patency, and so permit of the passage of some of the fluid or semifluid contents of the bowel into the genital passage. The anatomical position of the opening would account for its non-discovery by ordinary vaginal examination.

TREATMENT OF "PERNICIOUS ANAEMIA OF PREGNANCY" AND "TROPICAL ANAEMIA"

WITH SPECIAL REFERENCE TO YEAST EXTRACT AS A CURATIVE AGENT*

BY

LUCY WILLS, M.A.CANTAB., M.B., B.S.LOND.

MATERNAL MORTALITY INQUIRY, INDIAN RESEARCH FUND ASSOCIATION

(From the Haffkine Institute, Parel, Bombay)

The anaemias mentioned in the heading of this paper might well be described under the common title of tropical macrocytic anaemia; as, except for the accident of pregnancy, they are indistinguishable from one another, but can be separated from the numerous other anaemias occurring in the Tropics by the large size of the red cells, and by the presence, at some stage of the disease, of megaloblasts. In fact, these anaemias have the blood picture of Addison's or true pernicious anaemia, but differ from this condition in that the typical blood

* A full report of this work, and of the experimental work done in connexion with it, will appear in the *Indian Journal of Medical Research*.

picture is not associated with the other symptom-complexes which are so constant a feature of pernicious anaemia.[1] It is suggested, therefore, that in future these two anaemias be described together as tropical macrocytic anaemia.

TROPICAL MACROCYTIC ANAEMIA

This anaemia occurs in India as a distinct disease, frequently associated with pregnancy, and complicating, or complicated by, malaria, hookworm disease, and sprue. In an earlier paper[1] I dealt only with the idiopathic form, but further experience has led to the inclusion of the other types, as they all respond to the same treatment. They must, however, be distinguished from the severe small-celled secondary anaemias which frequently occur in the above-mentioned conditions, but which do not respond to the same treatment as the macrocytic type. The treatment of macrocytic anaemia is of considerable interest, and throws some light on the etiology of the condition. It is generally recognized that iron and arsenic, in whatever form they are given, are valueless—Chart VI shows the result of such treatment; there is no increase in the haemoglobin or in the red cell count. This is the common experience of all workers in India who recognize this form of anaemia; they also find that other lines of treatment, successful in secondary anaemias, are equally useless.

LIVER TREATMENT

The discovery of the efficacy of liver in the treatment of pernicious anaemia suggested a new line of treatment, which has proved very successful for macrocytic anaemia. The pregnant cases respond more slowly than the others, but apart from this the results in the two conditions are identical. As in true pernicious anaemia, the presence of severe sepsis inhibits the stimulating effect of liver. After considerable experience in treating pregnant cases, I am of the opinion that, where the condition is severe, with a haemoglobin value under 20 per cent., it is essential to give large doses of liver extract (up to as much as the equivalent of 600 grams of fresh liver daily) if a rapid response is to be obtained; the need of this is urgent, as such patients are likely to go into premature labour and die of heart failure. The first five days of treatment, during which a response cannot be hoped for, are thus always a time of great anxiety, and the death rate is likely to remain high until the women learn to report in the earlier stages of the disease. Even without the added strain of labour, many patients are admitted only to die of heart failure in the first twenty-four to forty-eight hours; the immediate prognosis in cases with difficult breathing is very bad. Once delivery is over and the next two days are safely passed, the majority of patients will go into a natural remission without any treatment, so that in such cases it is very difficult to gauge the efficacy of any cure. Once a good response has been obtained, the dose of liver extract can be reduced, and, later, replaced by liver meat if the patient will take it.

As stated above, the reaction to liver extract seems exactly the same as in true pernicious anaemia, but the conditions in women's hospitals are such that it is generally impossible to follow the cases through as in other countries. Indian women of the hospital class are uneducated, very frightened, and suspicious. Few remain long enough for a cure, and many leave in a pitiful condition. The demands of their homes are very pressing, and neither they nor their relatives realize the importance of treatment; if a woman can crawl she must attend to her home duties. Hence the records are frequently incomplete; but in such cases as have been followed up, a typical reticulocyte response, of the same order as in pernicious anaemia, is obtained, and the same rapid return to a normal blood count and picture occurs.

VITAMIN TREATMENT

The results of liver therapy, though not easily brought into accordance with the previously expressed suggestion that a deficiency of vitamins A and C is causally related to the anaemia,[1] support the view that this is essentially a deficiency disease. However, it was decided to give a trial treatment with a concentrate of vitamin A (generously provided by Messrs. Lever Brothers), associated with a diet rich in vitamin C. At the same time experiments with monkeys were arranged along the same dietetic lines.

The treatment of patients with vitamins A and C proved a complete failure, and the animal experiments showed that a deficiency of these two vitamins was not concerned in the production of such macrocytic anaemias. The latter experiments did, however, strongly suggest that some deficiency in the vitamin B complex was significant as a causative factor, and that vitamin B had curative properties. Experiments with patients were therefore begun, and marmite, a form of yeast extract, was selected as the most suitable preparation. The extract was supplied in bulk by the Marmite Food Extract Company, and a sample was very kindly tested by Dr. Harriette Chick of the Lister Institute. She reported it to be rich in both the antineuritic vitamin B_1 and the antidermatitis vitamin B_2, and comparable with yeast itself; a dose of 0.2 gram (dry weight 0.139 gram) was found to be sufficient for a rat's daily ration. The extract was given to the patients in drachm (1 drachm = 4 grams) doses, two, three, or even four times a day, the larger doses being used for pregnant women. It was found to cause nausea in a few of the very severe cases. This was overcome by giving it iced, and with the addition of crushed peppercorns; it was always taken cold, as the patients preferred it so. In the report given below it will be seen that the marmite was as active as liver extract in causing regeneration of red blood cells.

Before the case histories are given, it must be noted that only female patients were treated, as the author was working in women's hospitals; but similar anaemias occur in men, and this treatment is now being tried out on them also. The following histories cannot be taken at their face value, as the women do not give reliable information. A history of fever may mean nothing, as patients will assure you that they have fever when their temperature is consistently normal or subnormal. The mean red cell count for my series of healthy women of the hospital class in Bombay is 4.06 millions and the haemoglobin 69 per cent. (100 per cent. = 13.8 grams); these values indicate the degree of recovery which can be expected.

CASES TREATED WITH LIVER EXTRACT

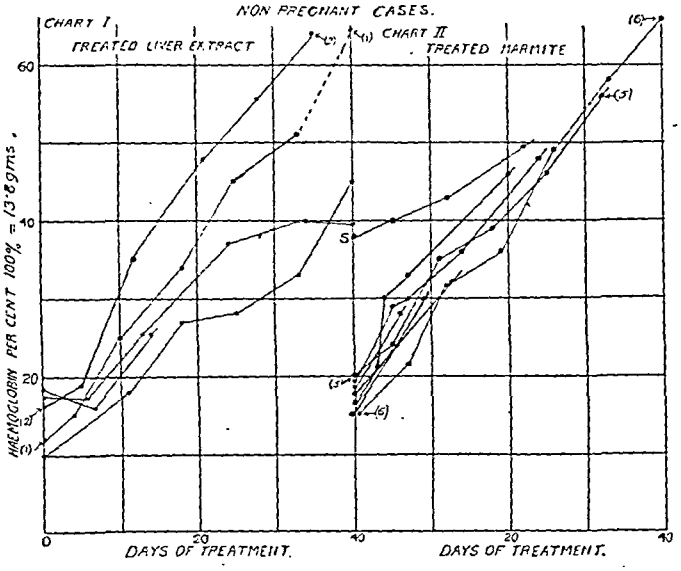
CASE I

Married woman, aged 27, 3-para, Hindu, strict vegetarian. Patient was confined five months ago; for fifteen days before delivery she had fever and swelling of the extremities; she improved for two months, but since then has had fever, increasing weakness, pallor, and oedema of the limbs. On admission she was semi-conscious, with a temperature swinging between 99° and 102° F. The extremities were oedematous; there was no diarrhoea; the urine contained a faint trace of albumin; the Wassermann reaction was negative; no ova were seen in the stools; and later, a test meal showed the presence of free hydrochloric acid.

The blood count showed: red blood cells 450,000 per c.mm., haemoglobin 12 per cent., white blood cells 900 per c.mm.; there was anisocytosis, with very large cells, and some poikilocytosis; megaloblasts were present. A reticulocyte count gave a percentage of under 1.

Treatment consisted of digitalis for the first week only, and liver extract (*hepatopson*) in doses equivalent to 250 grams of fresh liver daily. Clinical improvement was obvious in five days, and thereafter the patient made an uninterrupted recovery. Daily reticulocyte counts were not made, the

maximum response observed being 12 per cent. on the eleventh day. A blood count, after thirty-three days' treatment, showed: red blood cells 3,020,000 per c.mm., haemoglobin 55 per cent., and white blood cells 9,100 per c.mm., and the blood picture was normal; twenty-nine days later the red blood cells were 3,700,000 per c.mm. (Chart I, (1)).



CASE II

Married woman, aged 27, 1-para, Hindu, vegetarian. The patient was delivered five years ago; since then not pregnant. For four months she has suffered from fever associated with vomiting and oedema. On admission the patient was extremely ill, with a temperature of from 100° to 103° F. for the first six days; she also had a sore mouth, severe vomiting, a feeble rapid pulse, and a dilated heart, and she was very restless. The urine contained no albumin; there was very slight oedema. Later examination gave a negative Kahn reaction; ova were absent from the stools, and there was free acid in the gastric contents. A blood count taken on admission showed: red blood cells 820,000 per c.mm., haemoglobin 17 per cent., and white blood cells 5,000 per c.mm.; there was anisocytosis, poikilocytosis, and some polychromatophilia. Megaloblasts were present; very few reticulocytes were seen in the whole slide.

Treatment consisted of liver extract (hepatopson), equivalent to 250 grams of fresh liver daily, and later of Lilly's extract, equivalent to 300 grams fresh liver daily. Stimulants and glucose per rectum were given for the first few days. The temperature fell after six days, the vomiting ceased, and thereafter the patient made a rapid and uninterrupted recovery. After thirty-five days' treatment the blood count was: red blood cells 3,520,000 per c.mm., haemoglobin 64 per cent., and white blood cells 8,600 per c.mm.; the blood picture was normal. Daily reticulocyte counts were not done; and the maximum response observed was 8 per cent. on the twelfth day (Chart I, (2)).

The above two cases are typical of a series of non-pregnant cases treated with liver extract; further examples are shown on the same chart.

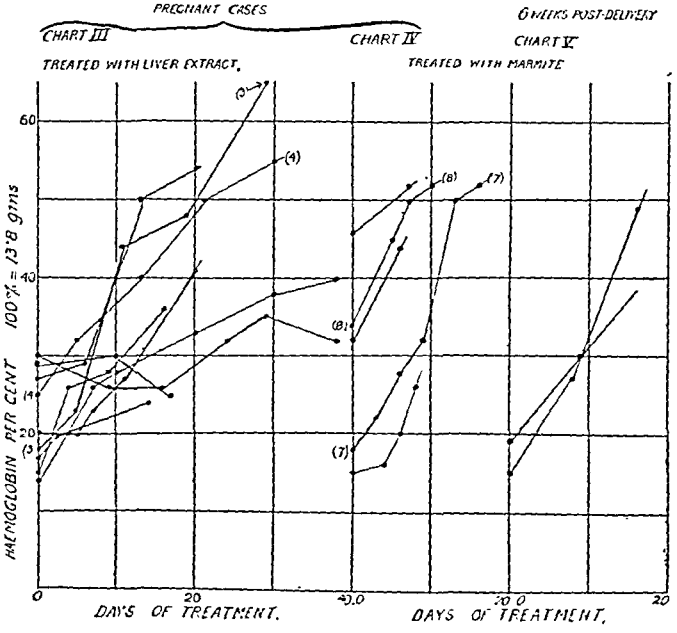
CASE III

Married woman, aged 21, primipara, six and a half months pregnant, Christian, and meat-eater. Patient gave a history of recurrent attacks of fever, probably malaria, since childhood; otherwise healthy, except for severe vomiting in the early months of pregnancy. For the last month there had been increasing weakness and fever. On admission she had severe anaemia, associated with great weakness, breathlessness, and moderate oedema of the extremities. She was very constipated; temperature was 99° F. The spleen was enlarged and hard. The urine contained no albumin; the Wassermann reaction was negative, and a few hookworm ova were found in the stools. The blood count showed: red blood cells 998,000 per c.mm., haemoglobin 18 per cent., white blood cells 11,200 per c.mm.; there was marked anisocytosis, a few megaloblasts, and a very few reticulocytes.

The treatment consisted of liver extract B.D.H. fluid extract) in doses equivalent to 700 grams daily, for nine days, and after that of half a pound of liver meat daily. Digitalis, 5 minims three times daily, was taken for the first few days. The result was an uninterrupted recovery. Thymol for hookworm was given after the red cell count had passed 2 millions. The maximum reticulocyte response was 39 per cent. on the ninth day. The final blood count on the thirty-third day of treatment showed: red blood cells 3,680,000 per c.mm., haemoglobin 66 per cent., and white blood cells 7,800 per c.mm. The blood picture was normal (Chart III, (3)).

CASE IV

Married woman, aged 28, 5-para, eight months pregnant, Hindu, vegetarian. The patient gave a history of one month's fever, weakness, and sore mouth. She was admitted with severe anaemia, great weakness, slight oedema, and a temperature of 100° F. The urine showed a trace of albumin. The Kahn reaction was negative. No ova were found in the stools. The test meal was negative for free acid, but the neutral chlorides were high. A blood count showed: red blood cells 1,080,000 per c.mm., haemoglobin 25 per cent., white blood cells 8,200 per c.mm., and the usual blood picture.



The treatment was carried out with liver extract alone (B.D.H. fluid extract) in doses equivalent to 250 grams daily. The temperature fell after fourteen days; the patient improved steadily, and was delivered at term of a healthy child. The maximum reticulocyte count observed was 12 per cent on the fifteenth day, but the count was not taken daily. The final

blood count before delivery, after thirty-three days' treatment, showed: red blood cells 3,250,000 per c.mm., haemoglobin 55 per cent., and white blood cells 6.500 per c.mm. The blood picture was normal. After delivery, on the fifty-second day of treatment, the red cells had risen to 3,420,000 and the haemoglobin to 60 per cent. (Chart III, (4)).

Cases III and IV are typical of those complicated by pregnancy which responded well to treatment; but, as Chart III shows, there were others in which recovery was slower. At the time when the majority of patients were treated, the dose of liver extract given (for various reasons, partly that of expense) did not exceed the equivalent of half a pound of fresh liver daily. In my opinion this is not enough to produce a prompt rise in the count in all cases; and it is probable that many of them would have done better on the larger doses now used. It is also possible that minor degrees of sepsis or other complications which inhibit the response to liver were missed.

CASES TREATED WITH MARMITE

The number of cases of tropical macrocytic anaemia treated with marmite was not large, in all twenty-two, many of which could be followed up only for a short time. The results of the treatment were, however, so striking that I feel justified in reporting them—more especially as I am leaving India, and shall not be able to continue the work. Further, it is hoped that other workers will be encouraged to give the treatment a trial.

This series consisted of eight non-pregnant women, seven pregnant, two puerperal, and five who were delivered during treatment. The non-pregnant patients, with the exception of one who had a severe *B. coli* cystitis, with much pus in the urine and acute bronchitis as well (Chart II, s), were uncomplicated by sepsis; all responded rapidly and well to treatment (Chart II). The clinical improvement was as marked as the changes in the blood. Two cases are reported in detail below.

The seven uncomplicated cases, treated ante-natally, were unfortunately followed up only for a short time, the longest period being eighteen days; but the improvement in four of them with severe anaemia was amazing; clinical improvement (less oedema, easier breathing, return of appetite) was apparent on the third day, and improvement in the blood on the fourth day (Chart IV). Two of these are reported in detail below. Two others, both with red cell counts under a million, died undelivered on the second and fourth day of treatment. One died suddenly and unexpectedly, after showing signs of improvement; but the other, a patient with general anasarca and vomiting, had little prospect of recovery from the beginning, as she could not sleep for breathlessness or retain any nourishment.

The two puerperal patients, delivered six and eight weeks before admission, had been going downhill ever since. Both were admitted with red cell counts below a million and haemoglobin values below 20 per cent.; and both had severe diarrhoea. The one had a temperature swinging between 100° and 105°, for which no cause could be found other than the anaemia and associated diarrhoea. On marmite alone (one drachm four times daily) this patient made an uninterrupted and rapid recovery, showing a reticulocyte count of 39 per cent. on the eighth day of treatment. The other patient had a *B. coli* cystitis and recovered more slowly, the maximum reticulocyte response being only 15 per cent. on the eighth day of treatment—an example of the inhibiting effect of any septic focus.

The five cases delivered during treatment were less suitable for a trial of a new remedy; and, with the exception of one, they were all complicated and responded slowly. In spite of this, four showed a typical reticulocyte reaction.

CASE V

Married woman, aged 25, 2-para, non-pregnant, Brahmin, strict vegetarian. The patient gave a history of two or three months' intermittent fever and increasing weakness. On admission her temperature was 99.8° F., and pulse rate 124; she was very anaemic, breathless, and had slight oedema of the face and extremities. The heart was dilated; there was a systolic murmur. The mouth was clean. The liver was enlarged to one fingerbreadth below the costal margin, and was tender. The temperature persisted for the first twelve days of treatment. The urine contained a trace of albumin, which cleared later; no ova were found in the stools, and the Wassermann reaction was negative. There was no free acid in the gastric juice, but so much bile that the test was useless. A blood count showed: red blood cells 917,000 per c.mm., haemoglobin 20 per cent., white blood cells 5,100 per c.mm.; and there was marked anisocytosis with large cells; only a few reticulocytes were seen. The patient was very ill, and the condition of her heart caused much anxiety.

The treatment consisted of marmite, one drachm twice daily, for the first twenty days, and then three times a day to help the appetite. Stimulants, digitalis, and camphor were given when necessary during the first four days. After this the patient improved remarkably, but the temperature did not fall to normal till the twelfth day, after which she made an uninterrupted recovery. The maximum reticulocyte count was 18 per cent. on the twelfth day. The final blood count, on the thirty-third day of treatment, showed: red blood cells 3,333,000 per c.mm., haemoglobin 56 per cent., and white blood cells 4,700 per c.mm. The blood picture was normal (Chart II, (5)).

CASE VI

Widow, aged 25, nullipara, non-pregnant, Brahmin, strict vegetarian. Patient stated that she had been healthy till four months before, when she had an attack of fever lasting fifteen days, followed by intermittent fever. She had complained of pain and distension for the last month, and vomiting for the last eight days. On admission the temperature was normal and the pulse rate 120. She was very ill, with extreme anaemia, oedema of the face and extremities, and a rapid and feeble heart beat. She was constipated, the tongue was coated, and she vomited several times. The liver was enlarged four fingerbreadths below the costal margin, and was tender. The spleen was not palpable. The urine contained a trace of albumin, which cleared later; no ova were seen in the stools, and the Wassermann reaction was negative. In a single test meal there was no free acid in the gastric contents. The blood count showed: red blood cells 812,000 per c.mm., haemoglobin 15 per cent., and white blood cells 5,600 per c.mm.; anisocytosis and poikilocytosis were present, megaloblasts were seen, and there were 0.3 per cent. reticulocytes.

One drachm of marmite was given twice daily, and stimulants and digitalis for the first week. The temperature remained normal after the first two days, but the rapid pulse and abdominal pain remained for some little time. On the eighteenth day of treatment, after the blood had shown a good response, both red cells and haemoglobin having doubled their original value, the patient had a rigor and rise of temperature, and malignant malaria parasites were found in the blood film. Whether this attack was a relapse or was due to an infection in the ward it was impossible to say, but after two injections of 5 grains of quinine the patient had no further attacks while in hospital, and made a good recovery. The maximum reticulocyte count was 35 per cent. on the sixth day of treatment. The liver remained enlarged. A final blood count on the fortieth day of treatment showed: red blood cells 3,544,000 per c.mm., haemoglobin 66 per cent., and white blood cells 5,200, and the blood picture was normal (Chart II, (6)).

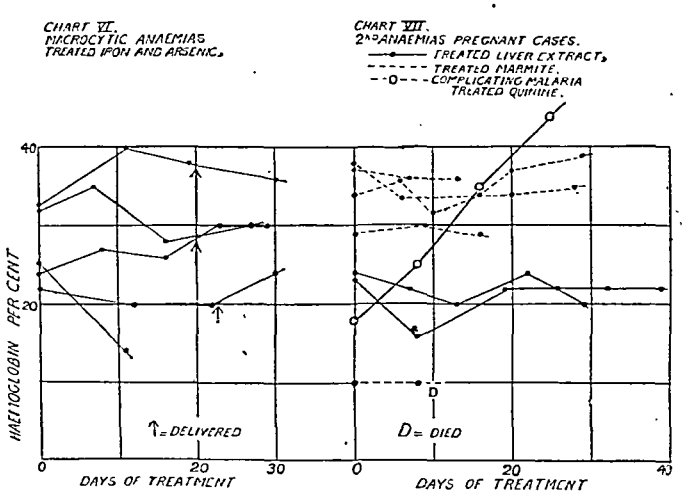
The two cases reported below represent two types complicated by pregnancy, the one typical of Bombay, with severe anaemia but only the moderate oedema associated with many severe anaemias, and the other of a type seen more frequently in Madras, with generalized anasarca as well as extreme anaemia. The latter variety is very

grave, and, admitted as they are in the last stages of the disease, the cases have a high mortality rate; the prognosis is particularly bad when a certain type of forced breathing is present.

CASE VII

Married woman, aged 20, first pregnancy, Hindu, but not a vegetarian. Patient gave a history of an attack of fever a year ago. She was six months pregnant, and had had diarrhoea for a short time. She was admitted with severe anaemia, marked breathlessness, oedema of the face and extremities, a rapid pulse, heart sounds poor with systolic murmur, dirty tongue, pyorrhoea, and severe diarrhoea, but no temperature. The spleen was enlarged; the urine contained no albumin; whip-worm ova were found in the stool. A blood count showed: red blood cells 990,000 per c.mm., haemoglobin 18 per cent., and white blood cells 8,200 per c.mm. Anisocytosis was marked, with very large cells; megaloblasts were present; very few reticulocytes were seen.

Digitalis, 10 minims thrice daily, was given for the first ten days, and, on admission, three powders, consisting of bismuth subnitrate 30 grains, salol 20 grains, and Dover's powder 15 grains. Marmite was given in doses of one drachm four times a day. For the first two days the patient was in a critical state, which was soon succeeded by a rapid and striking improvement. The diarrhoea stopped after five days, and the oedema cleared rapidly. The reticuloctye response was 56 per cent. on the fifth day. On the thirteenth day of treatment the blood count showed: red blood cells, 2,490,000 per c.mm., haemoglobin 50 per cent., and white blood cells 6,900 per c.mm.—an amazing response for a pregnant case. By the sixteenth day the haemoglobin was 55 per cent., and the patient feeling "perfectly well." (Chart IV, (7)).



CASE VIII

Married woman, aged 20, first pregnancy, sixth month, Hindu, but not a vegetarian. Patient was a coolie woman, and the only history she gave was of feeling ill and weak for seven days. On admission the most striking feature, other than the anaemia, was the generalized oedema; the whole body was swollen, and the labia stretched till they looked like tissue paper; there was free fluid in the abdomen, and moist sounds all over the chest. The patient was very breathless; the pulse rate was 64, and missing beats. There was marked pyorrhoea. The urine contained no albumin. Roundworm ova were found in the stool. The blood count was: red blood cells 1,300,000 per c.mm., haemoglobin 34 per cent., and white blood cells 8,100 per c.mm. Anisocytosis was marked, the cells being very large. A reticulocyte count gave a figure of 6 per cent.

The treatment consisted of marmite, one drachm four times a day, and nothing else. After two days of this the oedema was strikingly less; by the seventh day there was only a slight puffiness of the feet, and by the tenth day there was none. There was a reticulocyte response of 41 per cent. on the sixth day. On the tenth day the blood count showed: red blood cells 2,560,000 per c.mm., haemoglobin 52 per cent., and white blood cells 6,600 per c.mm. The cells were still large, and 5 per cent. of the reds were reticulocytes. Probably part of the initial rise in the blood count was due to the rapid decrease in oedema; but after all signs of this had cleared, the haemoglobin rose in two days from 45 to 50 per cent. (Chart IV, (8)).

DISCUSSION

The results recorded above suggest that in marmite we have a curative agent as potent as liver extract for the treatment of tropical macrocytic anaemia. The response of this disease to treatment with marmite is in all ways comparable with that produced by suitable doses of liver extract in the same condition or in true pernicious anaemia. Both extracts are active in this condition, even when it is complicated by malaria or hookworm, and without the treatment of the associated disease. This is in marked contrast with their complete inactivity in the secondary small-celled anaemia that so frequently complicates these infections (Chart VII). The fact that the two extracts are active in macrocytic anaemia raises the question of their etiological significance. The condition, both in its clinical manifestations and in its distribution, resembles a deficiency disease. The frequency and severity in pregnancy, the marked improvement that follows delivery (as in the case of deficiency osteomalacia), together with the frequent association of the disease with others that already lay a strain on the haematopoietic system, all suggest that some deficiency is the underlying cause. The geographical distribution is also suggestive, the regions chiefly affected being India, the Malay States, China, and the West Coast of Africa; the possibility of a infective agent cannot, however, be ignored.

If one considers the two extracts, the question of the nature of any common constituent factor at once arises. The work of Cohen,[2] Castle,[3] and their co-workers suggests that in liver extract it is a protein breakdown product that is active, and that in true pernicious anaemia it is some defect in the gastric function which leads to a failure of absorption of this product. In the tropical anaemia there is apparently no failure in gastric function.[4] It is possible, however, that the Indian diets, which are so markedly deficient in protein, especially animal protein,[4] may be deficient in this essential product or its precursor, and that the protein of yeast, known to be of good biological value, or its breakdown products, in the marmite supplies this want. The fact that the condition is so frequent among the better-to-do classes and among Mohammedans,[5] who are meat-eaters, would suggest that a protein deficiency is not the underlying defect.

Marmite is, however, known to be a rich source of the B vitamins, and so is fresh liver meat; commercial liver extract is also a very potent source of vitamin B_2, but it contains very much less of vitamin B_1. For a rat the minimum doses of liver extract for the two vitamins stand in the relation of even less than 1 to 10 (Chick, verbal communication); liver extract cannot therefore be called a rich source of vitamin B_1. The cases of anaemia seen in Bombay have no symptoms suggesting any marked deficiency of B vitamins, and beri-beri is practically unknown in the town. In Madras beri-beri occurs in all the rice-eating districts of the south and east coast, and endemic dropsy is also found in certain districts.

The frequent association of extreme oedema with the severe anaemia, and the fact that both respond so readily to treatment with marmite, are undoubtedly important. The question must, however, remain unsettled until further work can decide the common factor in the two extracts which is active. At present it is only possible to state that in marmite, and probably in other yeast extracts, there appears to be a curative agent for this dread disease which equals liver extract in potency, and has the advantage in India of being comparatively cheap and of vegetable origin.

In conclusion, it is a pleasure to acknowledge the help given by the staffs of the Cama and Albless Hospital, Bombay, and the Caste and Goosha Hospital, the Government Maternity Hospital, the Raja Sir Ramaswami Mudeliar Lying-in Hospital, and the Christina Rainy Hospital, Madras, who allowed me all facilities and showed the greatest interest in the work. The work was carried on as part of the Maternal Mortality Inquiry of the Indian Research Fund Association, which defrayed the expenses.

THE DIAGNOSIS OF URAEMIA

BY

A. ARNOLD OSMAN, D.S.C., M.R.C.P.

PHYSICIAN TO QUEEN MARY'S HOSPITAL; CONSULTING PHYSICIAN TO ST. ALFEGE'S HOSPITAL (L.C.C.)

AND

HAROLD G. CLOSE, M.B., B.S.

CLINICAL ASSISTANT, QUEEN MARY'S HOSPITAL; GRIFFITHS DEMONSTRATOR OF PATHOLOGY, GUY'S HOSPITAL

There is perhaps no condition in medicine which so frequently gives rise to difficulties and mistakes in diagnosis as that known as uraemia. This is partly due to loose definition and partly also to the fact that the manifestations included under the term, even when it is used in its strictest sense, are so varied as to simulate from time to time many other diseases. During the past twelve months, for example, cases have been seen in which, on clinical grounds, the following diagnoses were made: encephalitis lethargica, cerebral tumour, Addison's disease, pernicious anaemia, septicaemia, and leukaemia. A subsequent estimation of the blood urea, however, showed the true nature of the condition, which was confirmed at necropsy.

Now although many cases of chronic renal disease give no definite history of onset, and remain undetected for many years, all those mentioned above had had at least slight albuminuria; and uraemia, if considered at all, had been excluded on account of the absence of certain signs and symptoms generally considered necessary for this diagnosis. The absence, for example, of such symptoms as a high blood pressure, a hypertrophied heart, retinitis, foul tongue, the comparative youth of the patient, or even the small amount of albumin in the urine, had been regarded as making a diagnosis of uraemia due to chronic nephritis unlikely to be correct. The object of this paper is to point out the advantages of using the term uraemia in a more restricted sense than is usual; to emphasize certain clinical features which are of importance in the diagnosis, and which experience has shown are not sufficiently appreciated; and to bring forward a method of determining the blood urea which can be readily applied by anyone without laboratory experience or facilities.

DEFINITION OF URAEMIA

Strictly, the term uraemia should be applied only to those signs and symptoms which arise from, or at least are invariably associated with, defective elimination on the part of the kidneys; whether this be due to primary disease of these organs, a disturbance of their function secondary to disease elsewhere in the body, or to mechanical obstruction to the flow of urine—in fact, to those symptoms arising from an insufficient depuration of the blood by the kidneys. The word urinaemia is sometimes used to describe the results of mechanical obstruction to the urinary flow, but as the symptoms of this condition are identical with those of true uraemia as defined above it will not be employed here. It is true that none of the actual products of urinary retention has been proved to be the cause of the symptoms, but it is equally true that the accumulation of some or all of them in the blood generally leads to a definite train of symptoms to which alone the term uraemia is strictly applicable. Uraemia, therefore, can and does occur quite apart from Bright's disease. The term as commonly used includes many symptoms of this latter disease which are not always or necessarily associated with renal failure, as shown by nitrogen or dye retention or by diminished concentrating power of the kidneys. Particularly is this the case with regard to the symptoms of high blood pressure and cardio-vascular disease. These are often erroneously included under the term uraemia; but, as pointed out by Strauss, Ascoli, Widal, Volhard, Fishberg, and others, it is of great practical importance to differentiate clearly between those symptoms of pseudo-uraemia and those of true uraemia. As defined above, uraemia is seen in its most typical form in cases with mechanical obstruction to the flow of urine and in cases of chronic nephritis in the young; for although uraemia, as shown by nitrogen retention, etc., is frequently present in older subjects, death in these cases more often results from accompanying cardio-vascular disease.

SIGNS AND SYMPTOMS OF URAEMIA

The chief signs and symptoms of uraemia may be conveniently considered under the headings of the main systems of the body involved. The onset is usually insidious, but may be comparatively rapid, especially in acute nephritis, mechanical obstruction of the urinary tract, and in cases of chronic nephritis complicated by intercurrent infection, by bilious attacks, and following general anaesthesia. The initial symptoms vary, but physical and mental exhaustion, anorexia, vomiting, dyspnoea on exertion without signs of cardiac failure, marked anaemia, and progressive loss of weight are all common.

Nervous System

Mental apathy and drowsiness, quite apart from coma, are frequently present, and may be the only prominent symptoms for many weeks. They may be so marked as to lead to a diagnosis of encephalitis lethargica. If, in addition, there is some choking of the discs with a normal or only slightly raised blood pressure, as sometimes happens, cerebral tumour may be diagnosed. In some cases, on the other hand, there is intense mental activity, worry, and inability to concentrate, sometimes accompanied by a vague but insuperable feeling of alarm. Insomnia may be intractable, despite marked physical weakness and sense of exhaustion. Muscular weakness is often extreme. In one case seen recently it was the first symptom noted, and it increased in intensity for nine months before any other symptoms occurred, when anorexia was complained of. The blood urea was then 220 mg. per 100 c.cm. If at the same time the blood pressure is low or not much raised Addison's disease may be simulated. Most

of the various psychoses met with in these cases are probably due to cardio-vascular disease of the brain and not to uraemia. Muscular twitchings, especially of the extremities, are a frequent and important sign. They vary from fine fibrillary twitchings, confined to a few muscle groups, to comparatively coarse, jerky movements, often of the extensor muscles, occurring at fairly frequent intervals. Some patients complain bitterly of these twitchings and jumpings.

A healthy-looking man, aged 39, noticed that for the past six months he had been nervy and jumpy when doors were banged, etc. He was known to have had a trace of albumin in the urine for some years, but no casts had ever been found. Examination of the heart, blood pressure, and retinae showed nothing abnormal. While the pulse was being felt, however, an occasional slight involuntary jerking of the wrist and fingers was noticed. Because of this, a specimen of blood was taken, and the blood urea was found to be 190 mg. per 100 c.cm.

Muscular twitchings, then, are often a valuable clinical sign. Headaches are not a prominent symptom of true uraemia. They are often absent entirely, but when present are rarely of the intense variety met with in hypertension and vascular disease of the brain. The pupils may be contracted but exhibit no constant variation from the normal. Finally, it should be noted that vertigo, amaurosis, retinitis, transient pareses, hemiplegia, and, most important of all, convulsions, are none of them necessarily manifestations of true uraemia, but are probably symptoms of coexisting hypertension and vascular disease. In uncomplicated uraemia, in fact, they are generally absent.

Cardio-vascular System

It cannot be too strongly emphasized that a raised blood pressure is not an essential sign of uraemia. It does not generally occur as a result of urinary obstruction, and is frequently absent in cases of chronic glomerular nephritis (chronic interstitial nephritis or secondary contracted kidney) in young persons, and in chronic ascending nephritis or pyelonephritis in older people. Absence of cardiac hypertrophy at necropsy confirms these statements in many cases. Again, in cases of uraemia associated with chronic nephritis in which the blood pressure has previously been raised, a terminal fall of the pressure, not obviously due to heart failure, often occurs. This decrease in the pressure may take place days, weeks, or even months before death, and is often an ominous sign. It is important, therefore, to remember that an increased blood pressure is not always present in uraemia, even when due to chronic nephritis; and, in our experience, the diagnosis may be missed and the blood urea not estimated, "because the blood pressure is not raised." The only cardio-vascular disorders which might possibly be attributed to uraemic toxaemia are heart failure and perhaps pericarditis. Cardiac failure will, of course, accentuate or precipitate a fatal uraemia in patients in whom the kidneys are already damaged. One of us (A. A. O.) has often observed dropped beats, pulsus alternans, and sudden cardiac death, sometimes in cases of prolonged anuria due to various causes in patients in whom there was no reason to suspect previous cardiac disease. These cases, in fact, strongly suggested a toxic myocarditis, possibly caused by retained urinary products.

Alimentary System

Far too much importance is generally paid to the appearance of the tongue. It is described by some as dry, red, cracked, and glazed; by others, as covered by a brown or greyish exudate. Even taken into consideration with other symptoms, the appearance of this organ as an aid to the diagnosis of uraemia is practically without value. Only recently a case was seen at necropsy in which no blood urea estimation had been performed (a few hours after death the blood urea was 400 mg. per 100 c.cm.) and the diagnosis was missed although albumin had been found in the urine. The tongue looked normal, and it was thought that the patient, a girl of 16, was too young to have chronic interstitial nephritis. The kidneys were very small and granular.

A urinous or ammoniacal odour of the breath and stomatitis occur so late in the disease as to be without practical diagnostic importance. Bleeding of the gums and loosening of the teeth are also late manifestations, but are sometimes of diagnostic significance. Gradual loss of appetite over a period of weeks or months may sometimes be uraemic in origin. Nausea and vomiting frequently occur and may be persistent, leading to marked thirst and serious dehydration, very large quantities of fluid being lost in this way. Vomiting, with or without abdominal pain, may be the first symptom, and the chief difficulty arises in diagnosing this from the vomiting of high intestinal obstruction. In both, the blood urea may be very high, and the diagnosis turns chiefly on other tests. In uraemic vomiting, for example, the high blood urea is associated with a low plasma bicarbonate and a diminished concentration of urea in the urine. In the uraemia of intestinal obstruction the plasma bicarbonate tends to be increased (alkalosis) and the urinary urea output normal. Either constipation or diarrhoea may be present, but neither is of diagnostic importance.

Respiratory System

The respiratory symptoms of uraemia are not sufficiently distinctive to be of much value in diagnosis. Kussmaul breathing may occur, but differs in no way from that found in other diseases in which a terminal acidosis is the rule. The hissing respiration said to be characteristic of uraemia is a comparatively rare phenomenon, but is of some diagnostic value in the differential diagnosis of coma due to cerebral haemorrhage in which dyspnoea, if present, is accompanied by stertor. Increasing dyspnoea, especially on exertion, may be the earliest symptom, even in cases without heart failure or marked anaemia. Persistent hiccup is also a late manifestation, though not very common.

The Blood

Profound anaemia is sometimes the earliest manifestation of chronic progressive uraemia, and may lead to a tentative diagnosis of pernicious anaemia, leukaemia, or, when accompanied by fever and purpura, septicaemia. The anaemia is of the secondary type, and extremely low figures for red cells and haemoglobin may be encountered. Purpura is not an uncommon sign, though, in our experience, it only occurs late in the disease, and generally when the blood urea is at least 150 to 200 mg. per 100 c.cm. The platelet count is usually normal. Purpura and bleeding gums in an adult with even a trace of albumin in the urine should always suggest the possibility of uraemia.

The Skin

Occasionally a peculiar yellowish-brown waxy appearance of the skin gives rise to suspicion of uraemia. If there is also some puffiness of the eyelids a diagnosis of pernicious anaemia or myxoedema may be made, but in the majority of cases there is no characteristic tint or colour of the skin and no rash or eruption occurring often enough to be of diagnostic value. Pruritus may occur, but is not characteristic.

Progressive loss of weight not due to other ascertainable causes should excite suspicion and call for an investigation of the blood.

AGE INCIDENCE OF URAEMIA IN CHRONIC NEPHRITIS

It is not generally realized that fatal uraemia due to renal insufficiency (for practical purposes due to chronic nephritis) occurs chiefly in the young, and not in the elderly, a point which experience has shown to be a frequent stumbling-block in diagnosis.

Thus, of the last nine patients seen and diagnosed in hospital as chronic glomerular or chronic interstitial nephritis, and in whom small granular kidneys were found at necropsy, only three were over 25 years of age. The ages in these cases at death were 25, 25, 46, 19, 13, 20, 32, 37, and 20 years. Again, the average age at death of fourteen patients with chronic glomerular nephritis in whom the diagnosis was confirmed at necropsy, and who had during life a high blood urea (over 100 mg. per 100 c.cm.) but a systolic blood pressure under 150 mm. Hg, was found to be 27 years. In a further group of fourteen cases of chronic glomerular nephritis, confirmed at necropsy, with a comparatively low blood urea (under 100 mg. per 100 c.cm.) but with a systolic blood pressure of over 150 mm. Hg, the average age at death was found to be 47 years. Using the same criteria—namely, a blood urea of over or under 100 mg. per 100 c.cm., and a systolic blood pressure of over or under 150 mm. Hg—we analysed 100 consecutive post-mortem records from Queen Mary's, St. Alfege's, and Guy's Hospitals, of cases of chronic interstitial nephritis (primary and secondary contracted kidneys). These were divided into three groups.

(*a*) Uraemia=blood urea over 100 mg. per cent., and blood pressure under 150 mm. Hg.
(*b*) Hypertension=blood urea under 100 mg. per cent., and blood pressure over 150 mm. Hg.
(*c*) Mixed cases.

There were 20 cases in Group (*a*), 32 in Group (*b*), and 48 in Group (*c*). Of the 20 cases in the uraemic group the average age at death was 29 years, whilst the average age at death of the 32 cases in the hypertensive group was 47.5 years. Of the 20 subjects in the uraemic group, 12 were under 25 years of age, and of the 32 cases in the hypertensive group only 2 were under 25 years of age.

Clearly, in chronic glomerular nephritis death from true uraemia occurs more often in the young, the elderly succumbing chiefly to hypertension and cardio-vascular disorders. In the majority of cases, of course, some degree of renal insufficiency, hypertension, and cardio-vascular disease are all present. Incidentally it is worthy of note that of the nine cases referred to above only three were known to have suffered previously from renal disease of any kind, the other cases giving a history of weakness and malaise of a few weeks' duration only.

ESTIMATION OF BLOOD UREA

From what has been said above regarding the diversity of the clinical signs and symptoms of uraemia, and from our own experience of considerable numbers of such cases, we have been forced to the conclusion that, on the whole, laboratory methods are of more value in the diagnosis of this condition than the most extensive clinical experience, though a combination of both is the ideal. Reliance on purely clinical evidence alone, which, of course, includes a qualitative examination of the urine, will only lead to a correct diagnosis of uraemia in a proportion of cases. This in no way diminishes the importance of the most thorough clinical examination in every case. While uraemia due to true renal insufficiency is, as pointed out later, not necessarily present in every case in which a raised blood urea is found in association with albumin in the urine, a blood urea determination is, nevertheless, by far the most useful single test as an aid to diagnosis, and, taken in conjunction with the clinical features, will suffice in the majority of cases, though other laboratory tests may be necessary in special instances. This being so, and the condition itself being by no means uncommon, it is desirable that every practitioner should be able to estimate the blood urea for himself. In fact, this simple procedure should be regarded as just as essential to a medical man as the measurement of the blood pressure, a retinoscopic examination, or doing a blood count; the latter two, incidentally, requiring greater skill in execution and experience in interpretation than a simple estimation of the blood urea.

For these reasons we have devised a method, or rather a modification of the well-known method of Twort and Archer,[1] which is suitable for general use, and does not necessitate the use of elaborate apparatus and laboratory accommodation. The principle of the method is the conversion of urea to ammonia by the action of urease on the urea. Trichloracetic acid has been substituted for the tungstic acid used in the original method. An important feature is that venepuncture is avoided, as the estimation can be carried out on a single drop (0.1 c.cm.) *of blood obtained by pricking the lobe of the ear or the* finger. The estimation, which is performed by colour comparisons with standard colour solutions (thus avoiding the necessity for titrations, colorimeters, and calculations), can be carried out at the bedside, or the blood can be transported and the test performed at leisure. To carry out the complete estimation requires about forty minutes in all, but the operation may be interrupted, if necessary; at various stages. The degree of accuracy obtained is quite sufficient for all practical purposes, and can be increased by a simple alteration in the concentration of the solutions used. For most purposes it is only necessary to ascertain whether the blood urea is normal, or, say, twice or three times the normal. There is no point in knowing, for example, whether a given specimen of blood contains 80 or 85 mg. of urea per 100 c.cm.; it is sufficient to know that it is approximately twice the normal. With concentrations of urea over 200 mg. per 100 c.cm., a reddish precipitate appears, which makes it difficult to obtain accurate readings. This, however, is not of great practical importance, as the prognosis is uniformly grave with values of this magnitude and over. The method has been designed for use in general practice and for routine and emergency work in hospitals, but not for research purposes, for which the original method quoted above is more suitable.*

DETAILS OF THE METHOD

By pricking the finger or the lobe of the ear by means of the blood pipette 0.1 c.cm. of blood is obtained and added to 1 c.cm. of water in a test tube. A urease tablet is crushed and added to the contents of the test tube, which is then immersed in water in a water bath at 50° C. for fifteen minutes. To this 0.2 c.cm. of 20 per cent. trichloracetic acid is then added, and the mixture allowed to stand for ten minutes. It is then diluted with 3 c.cm. of water, and filtered through a piece of filter paper, previously well washed with water, into another test tube, until the volume of the filtrate is 5 c.cm. To three other test tubes 0.4, 1, and 1.5 c.cm. of the standard ammonia solution are then added, and the volumes made up to 5 c.cm. with water. To each of the four test tubes 1 c.cm. of Nessler's solution is then added, the contents are stirred, and are allowed to stand for two minutes. The resulting colour in the solution under test is then matched against a white background with the colours of the other tubes, which correspond to 40, 100, and 150 mg. of urea per 100 c.cm. of blood. Tap water is used throughout.

INTERPRETATION OF BLOOD UREA VALUES

The normal blood urea is generally given as 20 to 40 mg. per 100 c.cm. Values lower than this are often

* The necessary apparatus, etc., is contained in a convenient form in the "B.D.H. Ureamometer" made by British Drug Houses Ltd.

met with, especially in young fasting subjects. Low figures are also the rule in normal pregnancy (de Wesselow[2]). In elderly subjects the upper limit of the normal may be a little higher, and values of 50 or 60 mg. per 100 c.cm. are not necessarily to be regarded as pathological. Dehydration too, as after profuse sweating or residence in hot climates, may give rather higher values than normal. The protein content of the diet influences the concentration of urea in the blood to a considerable extent. Patients with chronic nephritis treated with a low protein diet may have a comparatively low or even normal blood urea. In spite of this, they may die from uraemia because the kidneys, although grossly disorganized, are able to deal for a time with a minimum load of urea, but not perhaps with other urinary constituents which are retained and may cause death. Generally such patients die from cardio-vascular accidents. It is important, however, to consider the diet when interpreting a blood urea value, from the point of view of either diagnosis or prognosis.

NON-RENAL CAUSES OF HIGH BLOOD UREA

A high blood urea, though indicative of uraemia, is not necessarily the result of disease of the kidneys, even if albumin is present in the urine. In heart failure, for example, the blood urea is often considerably raised and albuminuria is present; but other tests, such as the urea concentration test, show that the kidneys are functioning normally in respect of urea clearance. A high blood urea is also often encountered in fevers of various kinds, in septic conditions, and in the dehydration following severe diarrhoea. The intractable vomiting and dehydration of high intestinal obstruction are often, as mentioned previously, associated with a high blood urea.

It is not sufficiently realized that many general anaesthetics cause a distinct increase in the blood urea, which may last for some time. In this connexion we are kindly permitted to refer to some recent but unpublished work of our friend Dr. J. W. Shackle. Estimations of the blood urea before, and, at intervals, after, various forms of general anaesthesia, but particularly chloroform and ether and C. and E. mixtures, showed that quite frequently a normal urea content was doubled, and often took several days to return to normal. Moreover, the older the subject and the higher the blood urea before operation the more pronounced were these effects. In our experience, general anaesthesia given to elderly subjects, without a careful preliminary examination to exclude latent renal disease, is a not infrequent cause of unexpected death, following even the most trivial surgical procedures. In fact, we have been so impressed by this as to consider it justifiable to assert that no general anaesthetic should be given to a person over 45 years of age, except in emergency, without a preliminary estimation of the blood urea; especially if there is even a faint trace of albumin in the urine.

The value of blood urea estimations as a guide in the treatment of surgical affections of the kidneys and prostate, etc., is too well known to need discussion here.

We wish to acknowledge our indebtedness to the authorities at Queen Mary's, St. Alfege's, and Guy's Hospitals for permission to make use of their records and post-mortem material, and to the physicians at these hospitals for those cases not under our own care. Our thanks are also due to Professor R. Donaldson and Dr. Arthur Davies, directors of the pathological departments at Guy's and Queen Mary's Hospitals, for laboratory facilities; to the Medical Research Council for a grant for work of which this investigation forms a part; and to British Drug Houses Ltd. for the care and trouble they have taken in carrying out our wishes.

TWO CASES OF HAEMORRHAGIC PARATYPHOID FEVER

BY

R. M. WILLIAMS, M.B., B.S.LOND.

TEMPORARY ASSISTANT MEDICAL OFFICER, EASTERN HOSPITAL, L.C.C.

Early in February of this year paratyphoid fever broke out in Epping and its neighbourhood, and, at the suggestion of Dr. Shaw of the Ministry of Health, the London County Council decided to admit patients with this disease into some of its isolation hospitals. In all, some 240 cases were distributed throughout these hospitals. The origin of the epidemic was at first attributed to a contaminated milk supply. The history of the earliest cases, as far as can be ascertained from the case reports, dates back to December, 1930, and the age incidence varied from 2 to 78 years, the sexes being about equal in number. Examination of the stools and urine was performed two or three times on every patient admitted, and in every case showed the absence of the paratyphoid or typhoid organisms. The type of the disease, as evidenced by the temperature and the clinical symptoms, was very mild. The following is an account of the two deaths which occurred in the series.

HISTORY OF THE CASES

The two patients were brothers, William and Samuel, aged 11 and 13.

Past History.—Father dead. Mother resident in a mental hospital. Neither patient had any history of previous disease.

History of Present Illness.—Onset of the disease in both patients was on or about January 29th, 1931, with feelings of malaise in both about February 5th. Vomiting occurred on the following day in the case of William. Rose-red spots were present in both about February 7th. Samuel had haemorrhage per rectum on the 9th, previous to which he had had diarrhoea. Both boys were admitted together on February 11th in a delirious and febrile condition.

The point of interest in these two brothers was that they developed, practically at the same time, haemorrhages into the skin of the chest and abdomen.

CASE I

William, aged 11, was, on admission, an emaciated boy with sunken eyes. His colour was poor, pulse dicrotic, and temperature 99° to 104° F. Tongue was very dry and brown; throat injected and clean; sordes on lips and teeth; stomatitis present. Chest sounds were normal. The spleen was not palpable, and there were two rose-red spots on the abdomen. He was doubly incontinent, and, at intervals, delirious.

Course of Disease.—Low, muttering delirium; at times very restless; gradual weakening of pulse and heart sounds. On February 20th definite haemorrhages were present under the skin of the chest, and, to a slight extent, of the abdomen. He became extremely ill and was delirious; pulse was rapid and thready; hurried respirations indicated some degree of lung congestion. Temperature was remittent. On the following day the congestion had extended; the heart sounds became weaker (the first sound was almost inaudible), and the extremities cold. The petechial haemorrhages had not extended, but were very definite on the front of the chest and upper part of the abdomen. A blood count was done by Dr. Mair of the North-Eastern Laboratory at 3 p.m. on February 21st: white blood cells, 2,400 per c.mm.; differential count—lymphocytes 50 per cent., polymorphonuclears 18 per cent., immature cells 32 per cent. Most of the polymorphonuclears showed a myelocytic type of nucleus, and platelets appeared to be present in the usual numbers. Death occurred three hours later.

Post-mortem Examination

Post-mortem report on February 23rd—forty-eight hours after death—by Dr. Mair of the North-Eastern Laboratory. Subject emaciated, petechial haemorrhages present over the chest and upper abdomen. Abdomen: No peritonitis. Nothing abnormal about the mesenteric glands. Congestion of glands

and vessels in the great, and also in the gastro-splenic, omentum. Stomach, suprarenals, pancreas, kidneys, and upper intestine appear fairly normal on macroscopic examination. Lower intestine: Acute congestion of the ileum. No ulcers. No swelling of Peyer's patches. Acute congestion of ileum opening into the caecum. Some little congestion of the ascending colon. Transverse, descending, and pelvic colon normal. Lungs: Left—broncho-pneumonia of both lobes, the lower more marked. Right—lower lobe consolidated, marked broncho-pneumonia; upper lobe partly consolidated and in same condition. Culture from gall-bladder contents grew a pure growth of *Bacillus paratyphosus* B Widal; serum agglutinates *B. paratyphosus* B in dilution of 1 in 2,500; *B. typhosus, nil.*

Microscopical Sections.—Lungs: Marked broncho-pneumonia; all the blood vessels are congested, many of the alveoli are filled with red blood corpuscles, and there is a good deal of blood pigment; other alveoli are filled with catarrhal cells and leucocytes, which appear to be chiefly mononuclear. The lumen of one of the smaller bronchi is filled with a catarrhal exudate. The vessels in the wall of this bronchus are congested and the connective tissue is very cellular, showing marked proliferation of the fixed tissue cells. Gram-positive cocci could be demonstrated in the exudate, but no Gram-negative bacilli. Spleen: The lymphoid follicles are smaller than normal, but are very cellular. They give the impression that there has been active proliferation followed by exhaustion. The spleen pulp is congested and cellular. Kidneys: The vessels are congested; the glomeruli are swollen and cellular; and there is some degeneration of the epithelium of the convoluted tubules.

It will be noted that in this case the post-mortem examination by itself would not have led to the true cause of death—namely, paratyphoid fever. The serum was markedly positive, and a pure growth of *B. paratyphosus* B was obtained from the contents of the gall-bladder.

CASE II

Samuel, aged 13, was admitted on February 11th and died on February 20th, 1931. On admission he was thin and dehydrated. Tongue furred; throat was slightly injected, but clean. Abdomen: Nothing abnormal. Heart sounds were normal, but weak. Lungs: No adventitious sounds. Faint, brownish, lenticular spots were present over the abdomen and legs. The patient appeared extremely ill and toxic. He was delirious and at times restless. Pulse was dicrotic, colour was very poor, and eyes were sunken.

Course of Disease.—Swinging temperature, with marked remissions (from 99° to 104.8°). Low muttering delirium, with intervals of great restlessness. The rash faded about February 16th; later, definite *subsultus tendinum* and carphology were present. There was some degree of cough. On February 20th, at 10 a.m., there was a very profuse epistaxis, and petechial haemorrhages were present over the chest, abdomen, and back, but not on the face, arms, or legs. Over the pressure points (sacrum, trochanters, and back of the chest) the punctate haemorrhages amounted to definite ecchymoses. The general colour of the affected area was a fairly bright scarlet. Condition of the patient became rapidly worse—typhoid facies, delirium, running pulse, etc.—and death occurred suddenly at 4.20 p.m.

Post-mortem Examination

A very emaciated subject. Petechial haemorrhages general over the chest, abdomen, and back; over the pressure points (sacrum, great trochanters, etc.) there were definite purpuric patches, some as large as a five-shilling piece. Lungs: Early broncho-pneumonia; haemorrhages present in the lung substance. Abdominal viscera: No peritonitis. Definite congestion of the lower eighteen inches of the ileum. In the caecum, and round about the base of the appendix, a fairly large ulcer was seen with intense injection around. Smaller ulcers were present in the ascending colon (size varied from a shilling to a five-shilling piece).

Sections (report by Dr. Mair).—Intestine: Section of ulcer at lower end of ileum; the mucosa shows marked inflammatory change as indicated by proliferation of connective tissue cells and infiltration with lymphocytes; over two areas in the section the epithelium has completely disappeared. Section of ileo-caecal valve: The mucosa shows similar changes; over a considerable area the epithelium has almost completely disappeared. Spleen: The lymphoid follicles are ill defined, and there is an increase in the number of lymphocytes in the sinuses. Kidneys: The glomeruli are swollen and cellular, with congested vessels; some of the convoluted tubules show cloudy swelling, and necrosis of the epithelium. Liver: The portal tracts show an increase in the number of the lymphocytes present, and in the centre of the lobules there is some atrophy of the liver cells. Lungs: The smaller bronchioles are filled with polymorphonuclear and catarrhal cells; the vessels are everywhere engorged with blood; there are areas with haemorrhages into the alveoli; and some alveoli also contain catarrhal cells and polymorphs. Numerous Gram-positive diplococci and streptococci are seen. No Gram-negative bacilli were found. The condition is one of early broncho-pneumonia.

COMMENTARY

Eruption of purpuric rashes in the typhoid group is considered very rare. The late occurrence of such rashes is referred to by Dr. E. W. Goodall. The differential diagnosis of this condition from the purpuras is simplified by the history, the high Widal, the facies, the extreme degree of toxicity, and, finally, by the fact that the blood platelets were present in the usual numbers.

The blood reactions and examination of stools and urine were carried out at the Northern Group Laboratory, North-Eastern Hospital. My thanks are due to Dr. Pereira, the medical superintendent, and to Dr. Mair, for their kind help and permission to publish these cases.

CONTACT GLASS OR CROSSED CYLINDERS FOR HIGH ASTIGMATISM

BY

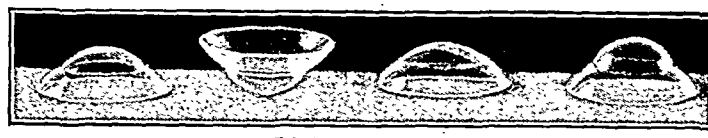
J. H. BEAUMONT, M.B., CH.B.NEW ZEALAND, D.O.M.S.

SENIOR CLINICAL ASSISTANT AND REFRACTIONIST, ROYAL WESTMINSTER OPHTHALMIC HOSPITAL; OUT-PATIENT OFFICER, ROYAL LONDON OPHTHALMIC HOSPITAL

Contact glasses are glass shells worn on the eyeball to replace an irregularly refracting surface of the cornea by the regular curve of the glass. They are not so uncomfortable as one might imagine. They are applied by the surgeon using a rubber sucker attached to the glass shell, the concavity of which contains saline or Locke's fluid. Holocaine 2 per cent. may be used as a local anaesthetic. The patient's head is bent forward, the eyelids separated, and the contact glass is fitted on to the eyeball, care being taken to avoid air bubbles. Contact glasses have a scleral curve, and also a corneal curve of shorter radius, so that the glass is in contact with the sclera but is separated from the cornea by a layer of saline. At first they should be worn only for about an hour a day. Enthusiastic patients soon learn to fit them on themselves. Professor Heine of Kiel uses the contact glass grounded by Zeiss. In Vienna they say that for some cases the older contact glasses blown by Müller are better tolerated, as they do not fit so tightly. Contact glasses should not be worn at night, because when the eyes turn up during sleep the cornea may become abraded. They are practically invisible, and do not interfere with movements of the eyes.

These glasses may be used for cases of conical cornea, irregular corneal opacities, high astigmatism, high myopia,

and high hypermetropia, and in cataract cases after operation. They are of great value in certain corneal conditions in enabling the patient to have useful vision. But they may also be employed for any refractive error, and there are possibilities for contact glasses even in the realm of sport. I know of a Canadian who wears them while flying in an aeroplane. They may even be worn in place of ordinary glasses by actresses or people not wishing to wear spectacles. It has been claimed that their temporary application has been followed by permanent loss of small degrees of astigmatism. They have also been suggested in cases of muscle imbalance, and in other cases where difficulty is experienced with ordinary glasses. They cost about £5 each wholesale. In Vienna I saw six hospital patients wearing them with satisfaction. They were prescribed even in cases of chronic ulceration of the cornea which had just healed. Instead of irritating the cornea, as one would have expected, they actually protected it from recurrence of ulceration.



Zeiss's contact glasses.

Müller's contact glasses. They have no corneo-scleral shoulder, and are blown by handiwork

CROSSED CYLINDERS

The crossed cylinders to which I am referring are two cylindrical lenses at right angles instead of the ordinary combination of sphere and cylinder. If a +8 D. cylinder at 90 degrees is combined with a −8 D. cylinder at 180 degrees the effect is that of a +16 D. cylinder at 90 degrees combined with a −8 sphere. In the following case the ordinary sphere and cylinder combination could only bring the vision from counting fingers to 6/36, while the crossed cylinders brought the vision to 6/6; this indicates the possibilities of this method. While admitting the improvement, I would condemn their continuous wear, as they cause so much distortion, except in a very limited central field. On the other hand, they may be of great assistance in investigating other cases.

History of Case

L. T., male, aged 42, salesman. This man was injured in a molten metal accident in 1912. Owing to failing sight he had to give up his work ten years ago. The right eye showed extensive lens changes with much thickening of the anterior lens capsule, but the cataract was not mature. The vision of the right eye was 6/18 (not improved with lenses) and J. 12 with difficulty. The left eye had a corneal opacity covering the nasal half of the pupil. There was pseudopterygium with two strands of adhesion of the conjunction of the lower lid to the globe. The high astigmatism had evidently been caused by the contraction of scar tissue. His left vision was reduced to counting fingers, and was not improved by a mydriatic. The retinoscopy of the left eye was:

$$+9 \quad +-9,$$

and with two crossed cylinders +8 D. cylinder at 10 and −10.5 D. cylinder at 100 the left vision was brought up to 6/9 and J. 1. But owing to distortion he was unable to recognize me with this correction at the other end of the room. With a contact glass, 9 mm. corneal curve and 12 mm. scleral curve, he read 6/6 and J. 1, with a 7 D. sphere. All his astigmatism had disappeared, and he had much more useful vision.

I am indebted to Sir Richard Cruise for his permission to publish this case.

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

INTERLOBAR EMPYEMA

Empyema between the middle and lower lobes on the right side is not very common.

The patient in this case was a woman of 40, admitted to hospital. She had, a month before, begun a pneumonia which involved the whole of the right lung and the base of the left. Her temperature, which was 103° F. at first, had come slowly down to 100°, but was never below that at night, and occasionally was higher. She looked very ill. There was an enlarged vein on the right side of the abdomen. The liver could be felt two fingerbreadths below the costal margin.

The right side of the chest moved very little. Resonance was diminished at the apex, and was less every interspace. From the fourth rib down there was complete dullness. Breath sounds were bronchial over the right upper lobe, bronchial with fine crepitations from the second to the fourth space, bronchial and less loud, with no crepitations, in the fifth and sixth spaces, weak, with a few crepitations, below that. Vocal resonance was increased in the third and fourth spaces, but absent below the fifth rib. The right back was dull from the spine of the scapula downwards. Fine crepitations and weak bronchial breathing could be heard from the spine of the scapula right down to the base. In the left chest there was rather puerile breathing, and some crepitations for three inches at the base. The heart's apex was only about half an inch outside normal.

I had a needle put into the fifth space about an inch outside the nipple line in the area where there was still fairly loud bronchial breathing, but vocal resonance had gone. Thick pus was withdrawn. At the operation next day quite a pint of pus was found between the middle and lower lobes of the lung.

Previous cases of this interlobar empyema that I have diagnosed have had very similar physical signs—a compressed middle lobe, with bronchial breathing, fine crepitations, and increased vocal resonance. In the fifth and sixth spaces external to the nipple line, where the empyema is nearest to the surface, and where the needle will strike pus, there is still quite loud bronchial breathing, but an absence of vocal resonance. At the back of the lung, crepitations can be heard down to the base. A rather deceptive point is that the heart is very little displaced, if at all, to the left, though the same amount of pus free in the pleura would displace it considerably. If undiagnosed this empyema may, with luck, open into the general pleural cavity, but more often it bursts into

a bronchus, in which case the patient may die of exhaustion from coughing up pus, or may develop a bronchiectatic condition, or, as in one case, a septic embolus may cause an abscess in the brain.

When operating it is as well to put in a long tube going up towards the hilum of the lung, as there is a considerable tendency for the lobes of the lung to come together and leave a pocket of pus near the hilum.

WALTER BROADBENT, M.A., M.D., F.R.C.P.
Senior Physician to the Royal Sussex County Hospital, Brighton.

SUBARACHNOID HAEMORRHAGE IN A CHILD

Children so often stand on their heads that one regards it as a normal exercise of childhood. The following case illustrates an unusual result. The mother of a girl, aged 10, gave me the following history.

For some time the child had not looked well, but had no definite illness. One morning she was very excited at the prospect of a party in the afternoon. As she has often done previously she stood on her head in an armchair. There was no history of any blow or knock on the head. On arrival at the party she played one game of "musical bumps" and then complained of feeling sick. She was sent upstairs to lie down, and vomited. She took no food at the party. On return home the vomiting continued. The sickness persisted all next day, and at the end of fifty-four hours I was asked to see the child. I found her in bed, complaining of sickness, with severe pain and aches in her back, and especially at the bottom of the spine. Also she had severe headache.

She is "an adenoid child" (tonsils and adenoids had been previously removed), and at this time she had some nasal catarrh. Her intelligence was good, and she was able to describe her symptoms very exactly. I provisionally diagnosed a meningeal type of influenza, and ordered a salicylate mixture. Next day I noted slight head retraction and a slight Kernig sign. There was some photophobia, and vomiting of a distinctly cerebral type. Intelligence good. Pain in back the same. Temperature not above 99° F.

On the third day after commencement of my attendance the head retraction became marked, also Kernig's sign and the photophobia. Pain in back less, but headache severe. No blurring of intelligence. Examinations of optic discs and ears were negative. I decided that it was time to perform lumbar puncture, and before doing so asked Dr. Lister to see the child. He agreed with me as to the need for a lumbar puncture, and she was removed to a nursing home. The provisional diagnosis was now probably onset of tubercular meningitis; but the very intelligent way in which the child described her symptoms made me reluctant to accept this diagnosis; I preferred to think the standing on the head had something to do with her condition. In the afternoon the lumbar puncture was done by Dr. Lister. The cerebro-spinal fluid showed blood uniformly, and we were able to make a diagnosis of subarachnoid haemorrhage of base of brain. Dr. Wordley examined the fluid and found no organisms, only blood distributed uniformly throughout it.

The progress to recovery was rapid. The patient had two severe attacks of nose-bleeding on two subsequent days. Headache and photophobia disappeared within two days, and all head retraction by the end of the third day. Within a week she was able to return home completely recovered, and there have been no after-effects.

MABEL L. RAMSAY, M.D., F.R.C.S.ED.,
Consulting Surgeon Gynaecologist, City Hospital and Public Dispensary, Plymouth.

OVARIAN PREGNANCY

On April 4th, 1931, a woman, aged 35, married for twelve years, who had never been pregnant, was seized with abdominal pain at 10 p.m. She was seen at her cottage in the country an hour later and found to have severe pain over the lower half of the abdomen, but was more tender and rigid in the left flank and iliac fossa. Her temperature was normal, pulse 78. She was brought into hospital forthwith and given one-third of a grain of morphine. Her condition being good and the diagnosis not clear, it was decided to watch her; the tentative diagnosis was either twisted ovarian cyst or ruptured ectopic pregnancy. Next morning her condition was good, temperature normal, pulse still 78; moderate tenderness and rigidity on left side as before. Examination showed an area of shifting dullness on the left side. Vaginal examination showed that there was no discharge, but the left fornix was full, and somewhat tender.

Menstruation had been quite regular all her married life, but her last period, which had come on a fortnight previously, was one week late; otherwise it was normal, lasting a week and clearing off a week before the attack of pain.

On the diagnosis of ruptured ectopic gestation, she was opened. The abdomen was half full of blood, the uterus was slightly enlarged, and both tubes were normal; but the left ovary was a good deal enlarged, congested, and had a ragged rent about one and a quarter inches long. The specimen was sent to Professor Tanner Hewlett, who reported as follows:

"The greater part of the ovary is occupied by a cyst the size of a walnut. . . . At the 'tube' end of ovary a haemorrhagic area is present, and sections show fibrous tissue and haemorrhages, together with large degenerate cells. These, I think, are decidual cells, and the condition therefore is one of ovarian pregnancy."

Two years ago I had a very similar case in which the signs and symptoms of early pregnancy were present, and the sudden onset of pain with acute abdominal symptoms, combined with the discharge of blood from the cervix, compelled the diagnosis of ruptured ectopic gestation. At operation the abdomen was full of blood, the uterus somewhat enlarged, both tubes normal, but one ovary was much enlarged, with a ragged bleeding tear in it leading to a cavity the size of a small walnut. It seemed obvious to my colleagues and myself that this was a ruptured ovarian pregnancy, but on mentioning the case at a discussion following a paper read at a Branch meeting, I was informed by a gynaecologist from a London teaching hospital that ovarian pregnancy was such a rarely recorded condition that this case could not be accepted as such in the absence of a microscopical examination. I regret this was not made, but I was ignorant of the rarity of the condition.

Neither patient gave a moment's anxiety after the operation.

Sherborne, Dorset. T. MACCARTHY, M.R.C.S., L.R.C.P.

Reports of Societies

B.C.G. IMMUNIZATION OF INFANTS

At a meeting of the Section for the Study of Disease in Children of the Royal Society of Medicine on June 9th, with Dr. HUGH THURSFIELD in the chair, Professor A. CALMETTE of Paris spoke on the immunization of infants with B.C.G. In introducing Professor Calmette, the Chairman said that the honour which he had done the Section in coming to give his address was a very great one. Professor Calmette then accepted a diploma of honorary membership to the Section.

Up to the present, Professor Calmette said, physicians in Great Britain had maintained a conservative attitude towards the use of B.C.G. To-day he hoped to convince his hearers that it lay in their power to suppress the mortality due to tuberculosis among children by means of a safe protective measure. In France B.C.G. vaccine

was distributed freely by the Pasteur Institute, and cultures were readily supplied to foreign laboratories. Since the discovery of the tubercle bacillus by Koch fifty years ago much research had been carried out on the various strains. Most people were spontaneously vaccinated against tuberculosis in early youth by means of frequent exposures to small doses of infection. Children might encounter the tubercle bacillus in their mother's milk, in food, or in dust infected by the secretions of persons suffering from active disease. Happily these repeated infections were usually sufficiently small, and occurred at long enough intervals of time, to permit of the development of resistance, so that the child underwent a process of auto-vaccination. The aim of Professor Calmette and of his veterinary colleague, M. C. Guérin, had been to secure, by artificial means, this sort of immunity, characterized by resistance to superinfections of tuberculosis. For this purpose it was useless to employ tubercle bacilli killed by heat, or bacillary extracts, since neither exhibited immunizing power. Nor was it possible to use spontaneously attenuated cultures, because of their tendency to recover virulence. Nevertheless, it was fully appreciated that only living bacilli would be efficacious in producing a lasting immunity, and it was in an attempt to isolate a strain of hereditarily and fixedly avirulent tubercle bacilli that Professor Calmette and M. Guérin had begun their researches nearly thirty years ago. Such a strain, they realized, would have to be comparable with Pasteur's anthrax vaccines, the bacilli producing tuberculin in artificial culture media, and having lost none of their antigenic properties in spite of their avirulence.

They had begun, Professor Calmette said, by injecting calves intravenously with attenuated cultures of the human type of bacillus, but it was found that when these calves later became milch cows a certain number of bacilli were secreted in the milk, constituting a possible source of danger to children. An attempt was also made to isolate a suitable strain by using the types of tubercle bacillus affecting birds, and even cold-blooded animals such as snakes and tortoises; but none of these was satisfactory. Eventually, by 230 passages on a highly alkaline lipoid-containing culture medium prepared with pure ox-bile, a strain was obtained which could be harmlessly used on cows, either as an inoculation or as an injection. After inoculation the animals showed resistance to the injection of virulent tubercle bacilli. This strain was known to-day as bacillus Calmette-Guérin, or B.C.G. The war had interrupted their researches, but when peace was declared they had been able to resume them. It was found that if newly born calves belonging to a herd of cattle infected with tuberculosis were inoculated with B.C.G., they could then mix with the herd without danger of contracting the disease. Professor Calmette and M. Guérin had then transferred their attention to monkeys —animals which are particularly liable to tuberculosis. The experimental monkeys were divided into three groups, of which those in the first group were inoculated with B.C.G., those in the second were infected with virulent tuberculosis, and those in the third group were left unmolested. All the animals were kept in the same cage. At the end of two years all those in the first group were alive and well; all those in the second group were dead and had been replaced by other infected monkeys; and of those in the third group four had contracted tuberculosis, and only one had escaped infection. Now convinced that B.C.G. was harmless to monkeys, the experimenters had wished to transfer their investigations to a human subject. An opportunity had arisen when a child came under their observation whose mother had died of tuberculosis two hours after the child was born; the grandmother, who was also infected, had charge of the baby. Although convinced that B.C.G. was safe, it was not without misgivings that they had undertaken the immunization of this child, but they had been finally brought to a decision by the thought that in such an environment the chances of its survival were otherwise negligible. Immunization was actually begun within a few days of birth, and now, after ten years, the child was alive and healthy: the grandmother had succumbed to tuberculosis two years previously. After making this first experiment Professor Calmette and his colleagues had realized that it was practicable to vaccinate children against tuberculosis by exposing them to an inoffensive infection as early as possible after birth, before they had been attacked by a virulent organism. Between 1921 and 1924 a small group of children, numbering 317, most of them born into tuberculous or suspected families, were vaccinated, with such encouraging results that in July, 1924, the Pasteur Institute had decided to put the B.C.G. strain at the disposal of any laboratory or physician desiring to study its effects. Since then research work involving the vaccination both of calves and of infants had been undertaken in many countries. The perfect innocuousness of B.C.G. had been established everywhere. A few authors, including Petroff, Watson, and Dreyer, had expressed doubts of the complete harmlessness and fixity of the strain, but a vast amount of experimental research work in laboratories throughout the world had proved that such doubts were founded on technical errors. It must be remembered that all vaccines made from dead organisms were mild and feeble, and the immunity they produced fleeting and brief. Only vaccines made from living organisms were efficacious. In a consideration of B.C.G., not only its innocuousness, but its efficacy, must be taken into account. During an examination of the effects of vaccination with B.C.G. carried out on a large number of children both of healthy and of tuberculous parents, it was found (*a*) that the infantile death rate due to tuberculosis among those vaccinated fell almost to zero, and (*b*) that the general mortality of vaccinated children notably diminished. It was not true to suggest that the vaccinated children were better fed or more carefully supervised than those who had not been vaccinated; analysis of the results by an impartial statistician had shown that no such error was operative. The fall in the general mortality suggested that the vaccinated children resisted disease better than the non-vaccinated, and possibly indicated the development of a non-specific immunity. In learning to resist B.C.G. the mesenteric glands had possibly developed their power of dealing with other organisms. In France 336,000 children had been inoculated up to May 1st, 1931, and there were now more than a million vaccinated children in the world: no accidents had occurred. The method produced the same resistance against virulent infections as a small fortuitous virulent infection, but without the same danger. The adoption of B.C.G. vaccination in all countries was desirable as a social measure against tuberculosis. The Pasteur Institute had put B.C.G. cultures gratuitously at the disposal of all the sanitary services in the world, thus enabling such services to prepare the vaccine, to distribute it free of cost, and to control its use. Professor Calmette hoped very earnestly to see English physicians become partisans of B.C.G.

In proposing a vote of thanks to Professor Calmette, Dr. ROBERT HUTCHISON said that conservatism had been carried too far in England in allowing the B.C.G. method of immunization to go so long without trial. The meeting had been sincerely impressed by Professor Calmette's clear and brilliant address, and he trusted that the method would now receive the attention in this country which it deserved. The vote of thanks was seconded by Sir W. DALRYMPLE-CHAMPNEYS.

STATE CONTROL OF THERAPEUTIC SUBSTANCES

At the annual meeting of the Fever Hospitals Medical Service Group of the Society of Medical Officers of Health, on June 12th, with Dr. SUTHERLAND in the chair, a paper was read by Mr. PERCIVAL HARTLEY, D.Sc., of the Standards Department, National Institute for Medical Research, on State control of therapeutic substances.

Dr. Hartley described the various therapeutic substances which came under the Therapeutic Substances Act, 1925, and pointed out that nearly all of them had certain properties and characteristics in common. The substances were markedly and sharply specific ; many of them were potentially very dangerous if improperly prepared, inaccurately standardized, or administered in an inexpert way, and, further, if the full benefit of their use was to be secured, the dosage must be precise, the practitioner must be able to adjust the dose to the condition of his patient and apply quantitative methods in his practice. In the short history of diphtheria prophylactic quite a series of misfortunes had been recorded in other countries, *some of them due to errors in manufacture, others to* mishandling of the product after it had been made. This country had benefited by the unfortunate experience of others, and he believed, thanks to the co-operation of many manufacturers, and to a certain extent to the application of the Therapeutic Substances Act, the possibility of accident from diphtheria prophylactic had now been reduced to vanishing-point. At an early stage in the study of these agents, it was clear that the amount of a particular substance must be accurately measured, otherwise there were no means of comparing the results of study in different laboratories, much less in different countries. It had proved possible to establish systems of measurement in this field of therapeutics. Practically all these substances had some specific distinguishing biological property. The laboratory worker found that definite quantities of these substances produced definite effects, and these were quantitative, some of them very sharply so. On this basis it had been possible to establish biological standards serving the same purpose as similar standards in physical science. A unit of biological measurement could be defined as the specific activity contained in a certain weight of the standard preparation. Standards, units, and systems of measurement had now been evolved for a great many of the therapeutic substances under discussion, and slowly their number was being increased. These standards were not merely national ; thanks to the League of Nations, international agreement had been secured in many cases.

The Therapeutic Substances Act was administered by regulations, the framing of which was carried out with very great care. First the regulations in countries where State control had been in existence were critically examined and adapted to British needs. The best expert opinion was sought on every point of importance. After three years' experience it was thought that some alterations might be necessary, and all the licensees under the Act were circularized and invited to make criticisms, but on no really large or prominent point was any modification asked for, showing that the first drafting of these important regulations had been well done. The licensing authority under the Act was charged with many important functions. If products of home manufacture alone had to be dealt with the problem would have been greatly simplified, and a supply of material of unimpeachable quality and purity would have been ensured by simpler methods. To ensure a uniform standard for the products of other countries presented no little difficulty, but a way of solving the problem had been found. In England the importing agent, not the foreign manufacturer, was licensed, and was made responsible for the foreign manufacturer's compliance with the regulations. This involved a good deal of inspection abroad and testing of foreign products at home. During the past year several import licences had been cancelled because of failure to satisfy the regulations in the matter of quality. A very important part of the licensing authority's duty was the inspection of premises and the examination of the finished product. It was impossible to examine samples of every therapeutic substance which went into circulation in this country ; regional medical officers, therefore, were asked to make a collection of a particular kind of material which the authority thought should be examined. This material was examined, as to labelling at the Ministry, and for potency, sterility, and so forth at the control laboratory. Last year 555 collected specimens were examined, covering practically all standardizable materials distributed under the Act. With regard to diphtheria antitoxin, fourteen samples were found below strength or otherwise not complying with the regulations, and as a result two foreign licences were withdrawn. Vaccine lymph needed careful control. As prepared for sale in this country, it must be free from gas-producing anaerobes and from haemolytic streptococci, it must contain less than a stated number of living visible micro-organisms, and must pass a test for potency. It was found last year that seven samples of vaccine lymph on one or other ground failed to reach the standard required. Appropriate action was taken, and in another case less drastic action was taken, the manufacturer being allowed to go on with the production of the substance, but required to submit samples of each batch to the Ministry before distribution. Two samples of pituitary extract failed to reach the standard, but these cases were dealt with short of withdrawal of licence. With regard to sterilized surgical ligatures, it was decided after long discussion that sterilized catgut should be controlled under the Act. A number of unfortunate happenings had occurred, chiefly in Scotland, owing to contaminated catgut, and the need for control was recognized. The manufacturers themselves agreed. Last year 138 varieties of catgut available for use by surgeons in this country before the Act became operative in respect to this subject were examined, and 42 were found to be contaminated. Nine applications were received for manufacturers' licences in England, and after tests and examinations of premises, only six were granted, and there were seven applications for import licences, of which five were granted.

Dr. R. A. O'BRIEN said that the prospect of the Act was at first somewhat alarming to those connected with production, but in operation it had proved welcome, and the Government staff deputed to carry out its provisions had been helpful in every way. He hoped that the Act would eventually deliver the industry from irresponsible standards. It was very disconcerting to find, with a certain substance alleged to have a standard value, that the people responsible for the standardization had altered the value of their original standards. The Act had also discouraged a certain specious accuracy. People had been too ready to talk of " units," and to imagine that that magical word meant that a standard of accuracy had been already attained.

Dr. E. W. GOODALL, Dr. J. D. ROLLESTON, and Dr. A. JOE added a few comments, all in commendation of what had been effected under the Act, and Dr. HARTLEY, in reply, paid a tribute to the people in this country who, prior to the Act, were working on this subject in the producing laboratories. One reason for legislation was that the superstructure which they had erected in England ought not to be jeopardized by the possible introduction of therapeutic substances of inferior quality.

Reviews

PIERSOL'S TEXTBOOK OF ANATOMY

Piersol's Human Anatomy[1] was first published twenty-four years ago, under the editorship of Professor G. A. Piersol of the University of Pennsylvania, with the help of half a dozen collaborators. Of the latter, only one now survives—as emeritus professor. The work of the original editor and his collaborators has been well rewarded by a popularity which has led to the production of successive editions. Now the ninth edition has appeared, under the supervision of Professor HUBER of the University of Michigan. One of the chief points of difference between this new edition and its predecessors is the consistent adoption of the B.N.A. nomenclature. The abandonment of what is usually called the "old nomenclature" in anatomy has become inevitable, in spite of the protestations—now growing less audible—of the older British anatomists. But we may perhaps, in passing, express the opinion that it is now time to revise the B.N.A. nomenclature in order to replace some of the cumbrous and misleading terms which are to be found therein. A few changes have been made in the revision of parts dealing with the histogenesis of the blood elements and the embryological development of certain systems concerning which views have changed during recent years. In the section devoted to the central nervous system the supervisor has had the invaluable assistance of Miss Crossby. This investigator has in the last few years completed a vast amount of detailed and laborious study on the comparative anatomy of the brain in vertebrates, and her work has been published in a number of voluminous papers in American journals. The reader may be certain, therefore, that the details of neurological anatomy in Piersol's textbook are dealt with in an accurate and comprehensive manner.

Of the text generally we have no criticism to offer. Perhaps it may be considered rather too long for the purpose of the average medical student (it runs into over 2,000 pages), and the volume certainly reaches the utmost limit in bulk for convenient use. The illustrations, we think, are not in keeping with the high standard of the text. They often lack the precision and clear simplicity which are so necessary for the production of successful anatomical figures. This is evidently due in part to the printing, as is apparent especially in the case of the coloured illustrations. It is unlikely that Piersol's *Anatomy* will be a competitor with Gray and Cunningham for the favour of medical students in this country. On the other hand, its comprehensive treatment of the subject in general, and the authoritative accounts given in sections such as that on the nervous system, render it an invaluable reference book to all those who may be primarily or secondarily interested in the science of human anatomy.

ANATOMICO-CLINICAL DIAGNOSIS OF DISEASES OF THE BREAST

The pupils of the late Professor Paul Lecène have dutifully arranged to bring out in a series of five monographs the material which their chief had for ten years been preparing for his *Les Diagnostics Anatomo-Cliniques*,[2] the first volume of which deals with general principles and diseases of the breast, by Dr. P. PAVIE and Dr. P. MOULONGUET respectively. It begins with a reproduction of some ten pages of Lecène's original manuscript of the preface. In discussing what the surgeon ought to learn from laboratory investigations, Dr. Pavie points out that Lecène regarded clinical, operative, and careful naked-eye examination as being supplemented by microscopical examination, which should be regarded as the fourth in the process of scientific investigation. In the section on the method of biopsy, stress is laid on the importance of sending to the laboratory with the specimen adequate clinical and anatomical details, and it is stated that without some information of this kind a conscientious morbid histologist should decline to give a report.

Nearly three-quarters of this finely illustrated volume is devoted to diseases of the breast, in which acute and chronic infections, dystrophies (such as hypertrophy), multiple cystic disease and adeno-lipoma, innocent and malignant new growths, and fat necrosis are described. The section on tuberculosis of the mamma points out the various aspects which this infection may present, the form simulating a galactocele being figured; Lecène never met with the non-suppurating sclerosing form which imitates cancer, but elsewhere an illustration of the combination of the two is given. Galactocele is included under the infections, as Lecène and Chifoliau showed a quarter of a century ago that it is due to subacute or chronic inflammation of the mamma. Lecène never saw an example of tertiary syphilis or of actinomycosis of the breast; but, as shown in a figure elsewhere, a necrotic carcinoma may simulate a gumma of the mamma. "Paget's disease of the breast," is preferable to the title "Paget's disease of the nipple," because, in Lecène's experience, the skin changes are always accompanied by lesions in the ducts in the substance of the breast, and further, as Lenthal Cheatle has shown, these changes in the ducts may occur without any alteration in the nipple. Fat necrosis, well shown in two coloured plates, is relatively frequent in fat women after injury, and, as it forms an ill-defined hard lump, adherent to the skin, may give rise to difficulty in diagnosis from malignant disease. This article, for which Dr. P. Moulonguet is responsible, is full of interesting information.

EXAMINATION OF THE LUNGS

The chapters in *The Physical and Radiological Examination of the Lungs*[3] embody the teaching given by Dr. CROCKET to his students at Glasgow University. It is nine years since the first edition was published, and the second is to a large extent a new book. Even the title has been altered. Two new methods of examination have been described and advocated in the intervening years—bronchography and bronchoscopy. The technique and results of the former are well described and illustrated. The latter is not dealt with, but its value is scarcely recognized in this country.

The various other methods of examination are described in detail, and stress is laid on the value of inspection of the patient, an important part of the routine examination so often neglected. The section on radiology is admirably illustrated by numerous radiograms. A chapter on the methods of examining a case gives to the student a systematic routine procedure for dealing with any patient presenting pulmonary symptoms. This will obviate the likelihood of anything important being missed when endeavouring to form an opinion and make a diagnosis. The author has wisely again included a well-illustrated chapter on the examination of the larynx.

---

[1] *Piersol's Human Anatomy*. Ninth edition, revised under the supervision of G. Carl Huber, M.D., Sc.D. London: J. B. Lippincott Co. 1931. (Pp. xx + 2,104; 1,734 figures. 45s. net.)

[2] *Les Diagnostics Anatomo-Cliniques de Paul Lecène*. Recueillis par ses élèves. (i) Généralités, par P. Pavie; (ii) Lésions du sein, par P. Moulonguet. Paris: Masson et Cie. 1930. (Pp. xi + 189; 92 figures, 2 plates. 45 fr.)

[3] *The Physical and Radiological Examination of the Lungs*. By James Crocket, M.D., D.P.H., F.R.C.P.Ed. Second edition. London: H. K. Lewis and Co., Ltd. 1931. (Pp. x + 286, 151 figures, including 40 plates. 16s.)

Without such an examination an investigation of the chest cannot be regarded as complete, particularly if pulmonary tuberculosis is suspected. The larynx is so intimately associated with the respiratory apparatus in its functions and its diseases that the omission of such a chapter would have been a mistake. An unusual feature is the thirteen-page glossary of terms and signs used in the physical examination of the lungs, which forms an appendix. It is usually difficult to find definitions of terms used in medical literature generally, and in connexion with diseases of the lungs in particular. It is a pity that so many signs and areas should still bear the names of the men who first described them. Such names as Troisier's sign (enlargement of the supraclavicular lymph glands), Burns's space (suprasternal), Damoisseau's sign and Ellis's line (the curved upper limit of a pleural effusion), and Mohrenheim's fossa (infraclavicular) are unnecessary and confusing, and might well disappear from modern textbooks.

By a curious convention the author has written this book "with special reference to tuberculosis and silicosis," and chapters are devoted to these diseases, while other important pulmonary diseases such as pneumonia, pleural effusion, bronchitis, and pulmonary neoplasm are scarcely mentioned. Since the book is primarily intended as a manual on the examination of the lungs for students, it is perhaps a little unfortunate that the author has allowed himself to particularize in this way, despite the great importance of the two diseases he has picked out.

PHARMACOLOGY OF QUININE

Quinine in general practice with regard to pharmacological knowledge,[4] by Dr. F. JOHANNESSOHN, is a monograph of 232 pages published by the Amsterdam Bureau for the Encouragement of the Use of Quinine. The author describes shortly the history, mode of preparation, and chemistry of quinine, but most of the volume is occupied by a discussion of the pharmacological actions and therapeutic uses of quinine and of quinidine. He explains in the preface that his purpose is to give an account of the actions exerted by quinine on the body as a whole, rather than an account of its specific action on the malarial parasite. In accordance with this intention he has provided a full description of the pharmacology and therapeutic uses of quinine and quinidine, and there is also a useful bibliography. Relatively little is said regarding the action of quinine in malaria, for this subject occupies only eight pages; moreover, in the section on quinine poisoning only two pages are given to blackwater fever. The book provides a full account of our knowledge of the general pharmacological actions of quinine, a subject that is often unduly neglected on account of the dominating interest of the problems relating to its specific action in malaria.

THE V.A.D. IN THE WAR

Four Years Out of Life[5] is an interesting account of the experiences of a V.A.D. worker during the war. It is an eminently human document, written in a light and entertaining fashion, without a single dull page. Its easy, clear descriptions contain much of a thoughtful nature beneath their bright exterior. Of the various combatant and non-combatant services, none emerged from the crucial test of war with a higher credit than the Volunteer Aid Detachments. Many of the girls who composed these units were brought up to regard tennis and garden parties as the important things of this life. Yet when the war broke out they realized what was at stake, and rose magnificently to the occasion. Less instructed and less practised than their sisters in the nursing services, they were none the less willing. Many had led careful, sheltered lives, which were a poor preparation for the stern realities of war. They were ready to perform any menial and unpleasant duty and to fill any subordinate position without hesitation and complaint. By their high endeavour and achievement they earned for themselves an honourable place among the forces of the Crown. These things are not insisted upon in the breezy pages of LESLEY SMITH'S most readable book: they are taken as a matter of course. She describes with a sure touch the routine of duty in a base hospital, the arrival of convoys of wounded and sick, the activities of the operating teams, and the hard, grinding toil of the sisters, whether trained or untrained. The vicissitudes of the weather, the unpleasant attentions of the German bombers, the cold and wet and the sad sameness of the mess-room meals, are all set down. In her constant subdued protest against the matron type of official, she reveals herself a rebel at heart. This does not appear to have affected her efficiency as a nurse or to have lessened her interest in her work. Soldiers who spent most of the war up the line, remote from hospitals, may be permitted to indulge a faint surprise at the wealth of lurid language those ministering angels are described as using. Is this, on the authority of Lesley Smith, to be accepted as correct? One wonders if it has not been perhaps too much dwelt upon in the pages of an otherwise thoroughly readable book, which shows unusual faculties of observation and powers of description.

CRIPPLED CHILDREN

Dr. EARL D. MCBRIDE of Oklahoma has prepared a guide for the help of nurses, masseuses, and other non-medical persons who may have the care of cripples. Nothing can take the place of first-hand practical instruction and demonstration by the orthopaedic surgeon, but such a vade mecum as *Crippled Children*[6] should be of considerable use for reference, or to refresh the memory. Although the treatment of deformities by operation is beyond the scope of nurses and social workers, some knowledge of the nature of operative proceedings improves the intelligent carrying out of post-operative measures and enhances interest in progress. Dr. McBride includes harelip and cleft palate in the crippling deformities of children, and gives indications of the operations needed for their relief. In discussing spastic paralysis he does not, in our opinion, give enough credit to Stoffel's operation, which many surgeons have found so useful when judiciously planned and performed. Royle's operation is not yet established in the position of a practical means of treatment. More might have been said, when discussing infantile paralysis, of the frequency and importance of paralysis of the muscles of the abdomen and trunk. The condition of the abdominal muscles is apt to escape detection when interest is centred on the more striking palsy of the lower limbs. The hints as to the fitting, application, and care of the Thomas knee splint are of practical value, and should be taken to heart by all who have to do with it. The chapter on plaster-of-Paris technique should also be useful.

ELEMENTS OF PHYSIOLOGY

Professors SCARTH and LLOYD, who hold chairs of botany in McGill University, have written a very interesting *Elementary Course in General Physiology*.[1] The book is divided into two parts, the first dealing with principles and theory, the second giving laboratory exercises. It is hoped that the work will serve as an introduction to the analysis of physiological processes in terms of physical and colloidal chemistry; it is especially intended for the use of students of medicine, biology, and plant physiology. The general plan adopted is to discuss the various processes in purely physical systems and then to consider their possible application to living cells. After an introductory chapter on the structure of the cell, various surface phenomena are discussed, and their importance is brought out prominently by the statement that there are 30,000 square metres of internal surface in the body. Surface tension is carefully dealt with—its cause, its relation to shape of cells, to protoplasmic movements, to ingestion and excretion by unicellular organisms, and the light it throws on the phenomena of leucocytosis; absorption is considered equally fully, and reference is made to the action of narcotics, to catalysis, and to post-mortem and vital staining. Chapters follow on osmosis and diffusion (in which problems of cell permeability are gone into), on H-ion concentration, on bioelectric potentials and currents, colloids, and enzymes. Throughout great pains are taken to make clear how the physico-chemical processes under discussion illuminate physiological problems.

This book will well repay careful study, especially by those who have not received a thorough grounding in physical chemistry. A good deal of the material dealt with and the exercises described might with advantage be brought into the regular medical curriculum. This would be a more useful branch of study than much of the inorganic and organic chemistry which is so widely taught at present, and could very well replace it to a large extent.

NOTES ON BOOKS

In writing *A Survey of Physics*[2] Professor FREDERICK A. SAUNDERS of Harvard University has endeavoured to steer a middle course between the popular presentation and the textbook for advanced students. His aim is to encourage "a thoughtful consideration of the subject by a choice of problems dealing with common things, but often in such a way that they cannot be solved by mere substitution in a formula." He uses elementary mathematics where necessary, but all the trigonometry needed for this book is summarized in a page and a half at the end. The letterpress is clearly written and clearly printed, and the illustrations are well chosen.

Having assumed personal responsibility for the first nineteen editions of his *Materia Medica, Pharmacy, Pharmacology and Therapeutics*,[3] Sir WILLIAM HALE-WHITE handed over the task of revision to Dr. A. H. DOUTHWAITE, and we now welcome the appearance of the twentieth edition of this deservedly popular handbook, whose features are too well known to need description. The general arrangement and style have been preserved, and brief additional notes inserted in order to bring the work into line with present-day knowledge. Among the new paragraphs in this edition are notes on ephedrine, quinidine, novarsurol, avertin, treatment by liver and gastric tissue, lipiodol, sodium tetraiodophenolphthalein and urosolectan, and Collip's parathormone. The vitamins also receive brief mention.

It is scarcely two years since we noticed the third edition of ASHHURST'S *Surgery, its Principles and Practice*, and now a fourth has been published,[10] testifying to the popularity of this general surgical textbook among students and practitioners in America. There is evidence of careful revision throughout the letterpress, and a good deal of new matter has been added at various places, including a number of new illustrations. Dr. Ashhurst's work as professor of clinical surgery in the University of Philadelphia has made him familiar with the everyday needs of his pupils and with the paramount necessity for broad foundations in the teaching of surgery. Among the subjects treated more fully in this new edition of an excellent book are rectal and spinal anaesthesia, injection treatment of varicose veins, hyperthyroidism, peptic ulcers, and tumours of the sympathetic nervous system; but it seems curious in a volume of nearly 1,200 pages to find only a paragraph of twelve lines on the therapeutic use of radium.

The thirty-fifth supplement[11] of *Acta Medica Scandinavica* consists of an essay by Dr. ALEXANDER JAROTZKY, professor of clinical medicine at Moscow University, on the dietetic treatment of gastric and duodenal ulcer based on the work of the Russian School of Physiology. The author holds that the principle in the rational treatment of hypersecretion and peptic ulcer is the avoidance of mixtures of fat and albuminous substances of animal origin. Several illustrative cases are recorded, and the details of suitable diet for subjects of peptic ulcer are given. An extensive bibliography is appended.

In his work on the *Social Control of Sex Expression*,[12] which is appropriately dedicated to Professor Edward Westermark, Mr. GEOFFREY MAY has made an interesting study of the control exercised by Anglo-American law over voluntary sex expression. The work is divided into three parts. In the first the author successively considers sexual repression among primitive peoples, the ancient Hebrews, and the early Christians. The second part, which is devoted to the periods from the Anglo-Saxon in English law, covers the periods from the Anglo-Saxon times down to the present day, special attention being given to the Puritan era and the Restoration. The last part deals with the doctrine in Anglo-American law in pre-revolutionary America and at the present day. A useful bibliography is appended. The author comes to the conclusion that while the methods of legal control of sex expression have varied widely throughout American history, the doctrine of sexual morality itself has not varied at all.

The eighth volume of *Proceedings of the University of Otago Medical School*[13] reproduces six papers published in medical and scientific journals between July, 1928, and October, 1930. The editor is Professor D. W. CARMALT JONES.

To the medical man, already overburdened with the terminology of his own profession, the *Illustrated Encyclopaedia of Motorcar Parts and Technical Terms*[14] will be welcome. It is the "Pocket Gray" of the car.

THE EFFECT OF RESEARCH ON CURATIVE MEDICINE

STEPHEN PAGET MEMORIAL LECTURE BY DR. H. H. DALE

At the annual meeting of the Research Defence Society on June 10th, with Lord LAMINGTON in the chair, the fifth Stephen Paget Memorial Lecture was delivered by Dr. H. H. DALE, F.R.S., whose subject was "The effect of research on curative medicine."

THERAPEUTICS AND EXPERIMENT

After an eloquent tribute to Stephen Paget, Dr. Dale said that, looking back over the comparatively short period of some thirty years which had elapsed since his own student days, he got the impression of a remarkable change in medicine. At the close of the last century the new knowledge that experiment had given was only beginning to make its way into the therapeutic aspects of medicine. Treatment then still largely depended on the administration of drugs, the use of which was based on tradition and empirical observation. He would not, for that reason, include them all in a hasty or general disparagement. Some of the old remedies held their own to-day, and with increasing value as experiment had shown the manner of their action and provided a rational basis for their use. There were many others, however, which were given without any real conviction of their value; the most that a weary scepticism expected of them was that they would not obstruct a tendency to cure by natural process. In striking contrast to this pessimism with regard to much of the older therapeutics was the clear conviction concerning the value of the few remedial agents which had already then come into general medicine through the work of the research laboratories. The physician who had known myxoedema as an incurable condition before Horsley's work and Murray's application of it did not give thyroid gland to such a case now with a feeling that it might do good and that it would in any case be harmless, but gave it with a knowledge of its practically certain efficacy. The physician in the isolation hospital who had had the heartbreaking experience of trying to cope with diphtheria in the days before antitoxin did not now give antitoxin with a feeling that it was at least harmless; he gave it with the knowledge that, if the case came early under treatment, the antitoxin would almost certainly effect cure.

Those were examples of therapeutic agents the remedial action of which had not been discovered by chance observation, like that of the older medicines, but had been arrived at by the logical process of experiment. Since those days the number had grown steadily. The example of insulin was already almost too familiar, but it had become so because of the dramatic change it had effected in the outlook of the sufferer from diabetes. Dr. Dale took another chemical substance produced by artificial synthesis, and chosen after laborious trial of many, as the one supremely efficient in attacking the infective microbe of syphilis. Its discovery would have been unthinkable without experiment on animals artificially infected. All the modern effort to control this scourge of human folly and to save the innocent from the danger of its contact would be crippled if salvarsan and its derivatives were no longer available.

He could multiply examples of the new potent remedies which the experimental method had given to medicine, but what he wanted to emphasize was the effect of research not only in producing new remedies, but in putting old ones to their proper use. He gave the example of ipecacuanha, the value of which had been enormously enhanced by experimental research. To anyone who knew the facts it was unthinkable that, without experiments on animals, there would have been obtained the clear knowledge now available concerning the parasites causing the different dysenteries. At the proper stage this method of experiment was essential. In due course, however, it led to a process of cultivating the dysentery amoeba artificially outside the human or animal body. His colleagues Dobell and Laidlaw, at the National Institute for Medical Research, had so perfected the process that this artificial growth of the amoeba on a dead medium could be continued indefinitely. The efficacy of ipecacuanha alkaloids in stopping the growth of this cause of tropical dysentery could now be demonstrated in a test tube. He begged his audience to think what that might mean for further progress. New substances likely to have a curative action on amoebic dysentery could now be given a first trial without the use of experimental animals, other than the amoeba itself. Let them compare the position which had thus developed under the intelligent use of experiment with that in which a really valuable drug, ipecacuanha, was for centuries used indiscriminately to treat a group of human diseases, on only one of which it had any effect, and was in the end deprived of its only valuable constituents to avoid a minor inconvenience of their action. Could anyone seriously face the possibility that some valuable new remedy might similarly find its true use only after centuries of confusion and misapplication, at an uncounted cost of human pain and sickness unrelieved or aggravated?

STANDARDIZATION OF REMEDIES

Dr. Dale went on to call attention to a particular need for the method of direct experiment in giving precision and safety to the use of many active remedies. In the case of potent vegetable drugs it was often possible, when once the active constituent had been identified, to determine the activity of a sample by an ordinary chemical analysis. When the methods were first found, however, of producing Nature's own remedies against certain infections by rendering a horse artificially immune against the corresponding bacterial poison, and separating from its blood the serum containing the natural antidote, a new problem of standardization presented itself. Such an antidotal substance could not be chemically distinguished from the constituents of an ordinary serum; it could only be recognized and estimated by its power of combining with the bacterial poisons so as to render it harmless; and this neutralization, again, could only be demonstrated by injecting the mixture into a susceptible small animal. On these lines, methods had developed by which the activity of some of these important new remedies could be measured as accurately as some of the older drugs could be measured by chemical analysis. The first of these natural antidotes to which such biological methods of measurement and standardization were successfully applied were the antitoxins against diphtheria and tetanus. Doses of these remedies came to be indicated, not in minims, ounces, or pounds, but in units of accurately measured activity. A new system of dosage, necessitating animal experiment for its indication, thus came into being with the advent of a new class of remedies, and the success of their application had depended very much upon it. As soon as a method had become available for thus measuring the activity of a serum with accuracy it gave rise to a new order of therapeutic usefulness. There were still cases in which the antidotal power of serum could not yet be measured with any approach to accuracy. For want of such methods of measurement the practical value of a serum was seriously compromised. Each new clinical use of an unstandardized remedy was not merely an experiment on man, it was a bad experiment, without adequate data, the result of which would make little contribution to

the general body of life-saving knowledge. Where accurate methods for biologically measuring the activity of one of these natural antidotes already existed, it was a duty, imperative on those concerned in its production, to see that the methods were regularly applied with skill and care; where adequate methods had not yet been found, it was equally the duty of those with opportunity to press on with research whereby such methods might result.

THE EXAMPLE OF INSULIN

Turning again to insulin, Dr. Dale said that there could not be a more striking example of the necessity for animal experiment in the direct biological measurement and standardization of activity of a naturally potent remedy. Without animal experiments the existence of insulin would not have been known; without animal experiments it could not have been, and could not yet be, prepared and tested so as to be safely and effectively used in the treatment of human diabetes. There was no other remedy with which such absolute precision in dosage was needed. The sufferer from diabetes, owing to lack of natural insulin in his system, had excess of sugar in his blood. The exactly right dose of insulin, repeated at proper intervals, would bring the sugar to within normal limits. Too small a dose would leave him with symptoms of diabetes; too large a dose would so empty his blood of its sugar as to produce alarming and even dangerous symptoms of a different kind. Far too little was still known about the chemical nature of insulin to be able to measure it or even detect it by a chemical test; the only way of indicating the strength of an insulin solution was in physiologically determined units. When the strength had thus been correctly determined and indicated, the doctor could adjust the dose to the particular patient's needs with remarkable accuracy, and the patient could go on, day after day, for long periods, taking the same dose. What would happen if these animal tests were omitted or inadequately done? The question had been answered by an actual experience. The obligation to standardize by animal tests was not adequately carried out in the case of a particular make of foreign insulin which appeared for a short time in this country. Reports immediately came in of patients who had relapsed into diabetes because one batch was too weak, or had suffered from dangerous symptoms because another batch was too strong. Samples were immediately tested at the National Institute, and were found to be in the one case weaker and in the other case stronger than the indications on the respective labels. Fortunately, the controlling authority had power to deal with the situation, and no more of such inadequately standardized insulin had been distributed. He asked again whether anybody was so confident in his opinions, so firm in his prejudice, that he was willing to say that regular tests on animals should be abandoned, and to put this forward as a practical proposal to the sufferers from diabetes or their relatives and friends. He added, however, that one kind of improvement which researchers always had in view was the discovery of a test for any of these substances which would enable the activity to be measured without the use of living animals at all. The researchers would much rather use chemical indicators in test tubes, always provided that these would give an equally good guarantee of the safety and effectiveness of a remedy which was to be used in treating the human patient. They would gladly spare the lives of mice, but not at the expense of the lives of men.

RESEARCH AT THE NATIONAL INSTITUTE

In conclusion, Dr. Dale gave some account of the work of the National Institute for Medical Research, and especially referred to the work on ultra-microscopic filter-passing viruses. It was hoped that new methods of study would bring about the result in respect to these viruses that the methods elaborated by Pasteur and Koch had done in respect of the visible bacteria. The discovery of such methods claimed all the patience, ingenuity, scientific experience, and discipline that distinguished investigators could bring to it in all parts of the world. The roll of honour of those who had fallen victims in the quest was a sadly long one, but on the success of such work depended real advance of knowledge concerning diseases as familiar as measles, mumps, chicken-pox, small-pox, so-called sleepy sickness, yellow fever, influenza, and even the common cold, as well as many diseases of domestic animals—foot-and-mouth disease, cattle plague, dog distemper, hydrophobia, and several others. Since the viruses causing these diseases could neither be seen with a microscope nor cultivated outside the living body, to prevent their study and investigation by the method of experiment on living animals would be to prevent their study altogether. The presence of such a virus could only be demonstrated, the quantity of it could only be measured, by experimental inoculation into a living animal. The hope of everybody concerned in such work, and the principal object of their investigations, was the discovery of methods for displaying the virus by some use of the microscope, and for cultivating it on some kind of lifeless medium, so that its nature might be brought under closer scrutiny without recourse at every stage to animal experiment. Hopeful progress in that direction was being made, and at an increasing rate in recent years. At present, however, the abandonment of experiments on animals would mean the practically complete cessation of the study of these deadly diseases, with all that it might afford of life-saving knowledge for men and for the animals themselves. Man's fruitful, conservative, and purposeful experiments would cease, but Nature's vast and destructive ones would continue.

A PERSONAL EXPERIENCE

Following the lecture Dr. R. D. LAWRENCE, who had suffered seriously from diabetes and was now healthy and vigorous after being treated with insulin, gave his personal experience with the remedy. The adult sufferer from the disease had, he said, before the discovery of insulin, the prospect of a living death for, at the most, four years; the average young patient died within two years of the disease being diagnosed, while infants died within two or three weeks of its being discovered, and this despite the best treatment which in those days the profession could offer. As one who had suffered from diabetes, which had once compelled him to give up his work and live for a time on a starvation diet, he was now able to say that he was mentally and physically strong, could work fourteen hours daily, and walk and climb as much as he desired. He felt so strongly about the people who opposed the testing and issuing of insulin that no other term than "well-meaning murderers" was applicable to them, and in that remark he believed he had the support of thousands of fellow subjects of the disease—they could scarcely be called sufferers now.

THE YEAR'S WORK

Viscount KNUTSFORD proposed a cordial vote of thanks to Dr. Dale, which was carried by acclamation. At the business meeting which followed, the annual report of the Research Defence Society was adopted. The society h. exercised itself during the year in securing opposition the Bill which sought to prohibit the expenditure of pu money on research, in the promotion of the standa tion and testing of drugs. Reference was made need for continual vigilance and activity, as in districts of the country an insidious campaign agai advancement of medicine by research was being on without opposition.

British Medical Journal

SATURDAY, JUNE 20th, 1931

INSURANCE SICKNESS CLAIMS

In the *Journal* of May 17th, 1930 (p. 914), there was an article on sickness benefit claims, based on a report (summarized in the *Supplement* of May 10th, 1930) by the Government Actuary on the sickness and disablement experience of a group of approved societies for the years 1921 to 1927. In that article the results set out in the report were described as "somewhat remarkable and disquieting," and it was stated that "some further investigation in certain directions is necessary and is being undertaken." This further investigation has now resulted in a very important memorandum on certification of incapacity for work (Memo. 329/I.C.), issued by the Ministry of Health and the Department of Health for Scotland to insurance practitioners, and a corresponding circular (A.S. 278) issued to approved societies. These publications demand the early and close attention of all bodies and persons concerned with medical certification under the National Health Insurance Acts. It is much to be regretted, however, that the Ministry, before drawing any final conclusions from its investigations, did not submit the facts disclosed to the Insurance Acts Committee for its observations. Previously the Ministry had invited the committee to co-operate in discussing the problems raised by the increase in sickness benefit claims, and the committee had suggested to the Ministry action which it might be useful to take with reference to any possible laxity of certification on the part of insurance practitioners. The committee had every right to expect that this co-operation would continue, and that it would be brought into consultation before any public pronouncement on the subject was made. The Ministry has, unfortunately, preferred to take independent action without reference to those with whom it was supposed to be associated in the consideration of a very difficult matter. Its inferences from the facts may well be disputed, and have far less authority than if they had been agreed findings.

As to the facts themselves there is no dispute. Since the issue of the Government Actuary's report referred to above, it has been common knowledge that between the years 1921 and 1927 there was an extraordinary rise in sickness and disablement claims. The actual figures are worth repeating. As regards sickness benefit the claims of men rose by 41 per cent., those of unmarried women by 60 per cent., those of married women by 106 per cent. As regards disablement benefit the percentage rises were 85, 100, and 159 respectively. The increase was shown to be in the proportion of members claiming, and not in the duration of claims, and to be most pronounced in short illnesses. There was some improvement in the year 1928, but the position in 1929 was substantially the same as in 1927. In 1930 there was again some improvement. Two further inquiries have been undertaken. The first of these was a careful scrutiny of the results of references to the regional medical staff during 1929; the second was an inquiry into the actual physical condition of a representative sample of insured persons in receipt of benefit on May 5th, 1930. The former investigation showed that 58.5 per cent. of those referred ceased to receive benefit as the result of the reference, the proportion among women being much higher than among men, and the proportion for short illnesses much higher than for those of longer duration. The latter investigation showed that the number of final certificates issued on the two days before receipt of notice of reference was 359, while the number issued on the day of notice and the following day was 749. The broad conclusions drawn by the Departments from all these inquiries are that a substantial proportion of insured persons claim benefit who are not strictly "incapable of work" as understood in the insurance scheme; that the proportion is greater in lower age groups than in higher, and in illnesses normally of short duration; that the proportion is greatest in the case of married women within child-bearing age, higher for married women than for the unmarried, and higher for unmarried women than for men.

The checks upon improper claims for sickness and disablement benefit are: (1) medical certification, and (2) supervision by societies. Under the latter are included prompt scrutiny, effective sickness visiting, correct record keeping, with periodical analysis of expenditure among classified groups of members, and adequate and judicious use of the regional medical service. These are all duly emphasized in the circular issued to approved societies, and they should be recognized as collectively of the first importance in checking improper claims. It is interesting to note that the Ministry and the Scottish Department once more call the attention of societies to the facts that "improper statements made by local agents and visitors regarding a member's right to benefit embarrass medical practitioners in dealing with insured persons"; and that "notwithstanding repeated warnings, cases still arise of requests being made to doctors for the issue of certificates on particular days of the week; also cases in which doctors have been requested, at the instance of societies or their representatives, to alter the dates on certificates." "The Departments look to societies to see that effective steps are taken to ensure that their representatives are warned against these practices."

The memorandum to insurance practitioners is concerned with the other check upon improper claims; and the conclusion is that "the main factor in the general increase has been an increase in payments to persons who were not incapable of work," and that "responsibility for this must be put, in the first place, on medical certification." This is a serious conclusion, and must be faced. It might be true, as stated, if it read "a main factor"; for the facts upon which it is based, and the logical process by which it is reached, are clearly and moderately set out

in the memorandum, and weight has been given to some of the considerations, which must be borne in mind in drawing inferences from available relevant statistics. Yet the extent to which "the main factor" is as stated, and the relative degree of "responsibility" to be assigned to imperfect medical certification, may well be in question. Others will not be as confident as the Departments that certain explanations of the situation have been eliminated, and it is quite possible that greater importance ought to be attached to certain factors which the memorandum rules out of account.

The memorandum states three possible explanations of the increase of claims for benefit since 1921—namely, "(*a*) a great increase in incapacitating sickness, (*b*) a tendency of persons incapable of work who would not have claimed in earlier years, to claim under present conditions, and (*c*) an increase in the number of admitted claims by persons who are not incapable of work." It may be agreed that (*a*) can be dismissed. It is said that "(*b*), although doubtless true to a limited extent, is quite inadequate as an explanation of the great increase that has been observed." Again, it may be agreed that this is not a complete explanation, but it should be given far greater weight than is assigned to it. The memorandum states: "That there are such cases is, of course, a matter of common knowledge, but it has never been suggested that they are sufficiently numerous to have a substantial effect in producing the observed differences in payment of benefit." On the contrary, this *has* been suggested, and it is here and now suggested, as producing a substantial effect, and even as being a "main factor" in the situation. It must be remembered that the initiative with regard to certification lies not with the doctor, but with the insured person. The first certificate and intermediate certificates are, by rule, to be given "if so desired by the insured person," or "if the insured person so requests," provided that there is "incapacity." It is true that in a great many cases the doctor has to advise, even insist on, absence from work; but though it may be true, as the memorandum puts it, that "patients cannot be held responsible for the estimates of their own incapacity except in the rare cases in which they seek to deceive," nevertheless these estimates often have to be taken into consideration, and may form a very important factor in arriving at a judgement in cases where gross physical signs of disease are not present. Whatever the reason, there can be no doubt that this exercise of the rights of an insured person, this initiating of a claim, has occurred in a far larger proportion of cases of "incapacity" since the year 1921 than before; and this has been the case precisely in short illnesses, and mainly with the younger generation of insured persons.

Again, it is probable that the memorandum does not attach due weight to the number of those "who, though really unfit for work, prefer to forgo the benefit which they might otherwise continue to receive rather than undergo medical examination" by a referee. Of course, every effort should be made to remove unreasonable apprehensions, but experience seems to show that the proportion of such patients to those who are actually summoned to attend referee sessions may be as high as 4 or 5 per cent.—a proportion "sufficiently large appreciably to affect the inferences that could otherwise be drawn from the facts." Such persons often do not seek a final certificate and resume work at once; rather they tend to return to work after a longer or shorter interval without receiving a final certificate at all. Nevertheless, it may still be true that "a substantial proportion of those who at any particular time are receiving sickness or disablement benefit are persons who are not incapable of work," and that in a proportion of these cases a requisite check has been inadequate in that "a number of certificates of incapacity have been issued which were not justified by the condition of the patient at the time of issue." This inference is fortified in the memorandum by two circumstances, in addition to facts such as those already cited. These are "the comparative study of the results of references of patients of different practitioners"; and the reasons given by practitioners when asked for explanations of their certification. There may easily, however, be fallacies in the former comparison, for even within such a centre as Birmingham or Manchester there may be many varieties of practice. As to the reasons given, some doctors admitted being governed by purely humanitarian considerations, while "a substantial proportion of the practitioners interviewed stated that they found themselves unable to certify strictly for fear of losing patients." The general body of practitioners may have some sympathy with these feelings in particular cases, but the attitude of mind indicated cannot be tolerated by the profession. It is clear that there is room for instruction among such practitioners, both as to the principles on which insurance schemes are based, and as to the conduct which is to be expected from a doctor even when his financial interests are involved. The Ministry and the societies are entitled to ask for firm action on the part of the medical profession, especially when it is recognized, as the memorandum says, that "the standard by which many are judged to have failed in their issue of certificates is that afforded by comparison of the results of their work with that of a large number of their colleagues," and even though "a considerable proportion of errors in certification are not due to such failings as lead also to errors of treatment."

The Departments concerned propose to take action in appropriate cases in accordance with the new Regulation recently made on the initiative of the Insurance Acts Committee. Such action includes investigation of the facts in individual cases by the regional medical officers and reference to Panel Committees of cases that appear to call for this. The recent action by the Minister of Health, taken in spite of the protest of the medical profession, in altering the freedom of an insured person to change his doctor, is not referred to in this connexion. It is obviously futile with regard to those cases for which the alteration was ostensibly made. If

a doctor is induced to be lax in his certification by the fear that he will lose his patient, he is not likely to be reformed merely because the loss may occur in six weeks instead of two. It is to be hoped that this new arrangement will speedily be abandoned.

The whole matter will be considered by the Insurance Acts Committee at its next meeting on July 2nd.

THE VALUE OF B.C.G. VACCINATION

On the occasion of his recent visit to lecture at the Royal Society of Medicine, on "Preventive vaccination against tuberculosis with B.C.G." (of which a report appears at page 1070), Professor Calmette left no doubt in the minds of his audience of the seriousness with which he regards the conservative attitude of the medical profession in this country. It is noteworthy and significant that the majority of those present at his lecture had come to hear the man; those who were well acquainted with his work mostly stayed away. This circumstance really affords the key to the present attitude of British workers towards B.C.G. Professor Calmette has failed by his animal experiments to convince the bacteriologists, and by his human experiments to convince the statisticians. His logic is excellent, but his premisses are unproven. Not until he or other workers can bring more convincing evidence in favour of his particular method of vaccination is there likely to be any general movement to adopt his methods in this country.

Let us consider the question in as dispassionate a manner as possible, leaving aside all reference to minor issues. For the sake of convenience we may deal with three main questions in turn. First of all, "Is it possible to produce by artificial methods a significant degree of immunity to tuberculosis?" There are certain diseases, of which the most important belong to the filterable virus group, which leave behind them a comparatively solid immunity. Second attacks of small-pox, measles, poliomyelitis, or distemper, for example, are uncommon, and against certain of these diseases it has proved possible to prepare a vaccine which can give rise to a definite and fairly lasting increase in the resistance of normal subjects. The immunity conferred by vaccination is rarely as sound as that resulting from a natural attack of the disease, and is by no means absolute. Vaccination against small-pox, for example, unless recently performed, does not afford certain protection against infection, though it diminishes the severity of the attack and lowers the case-mortality rate. On the other hand, there are diseases, of which tuberculosis and syphilis are outstanding examples, which leave behind them only a very slight degree of immunity. Second attacks of clinical tuberculosis are not only not uncommon, but they are, in fact, very frequent. That is to say, infection with the fully virulent bacilli may fail to produce anything but a slight and transitory increase in resistance. Is it likely, therefore, that vaccination with an attenuated virus is going to be any more successful? The direct evidence that is available on this point—namely, the prophylactic effect of living human bacilli on cattle—indicates that the immunity resulting from infection with virulent bacilli is better than that resulting from vaccination with avirulent bacilli. On purely *a priori* grounds, we may conclude, therefore, that no form of artificial immunization against tuberculosis is ever likely to produce a higher degree of immunity than that which can be produced under the most favourable natural conditions. Anyone who sets out to do more than this is, to borrow the words of Professor Neufeld,[1] chasing a phantom.

Secondly, "Has it in fact proved possible to produce an immunity to tuberculosis?" According to Calmette more than a million children have been vaccinated with B.C.G. in the last seven years or so. One would have imagined that during this period sufficient evidence might have been collected to answer this question definitively, yet it is clear from the work of Greenwood[2] in this country, of Wolff[3] in Germany, and of Rosenfeld[4] in Austria, that the statistical results are unconvincing. The fallacies in the French figures cannot be considered here in detail; suffice it to say that the groups of vaccinated and of non-vaccinated infants have not been comparable, and that the estimate of mortality which would have occurred in the vaccinated group, if vaccination had not been performed, has been based on assumptions for which there is insufficient justification. No simple criterion for assessing the value of the vaccine is available. Reduction of the death rate from tuberculosis during the first year of life among the general population is too crude a measure to employ; for, as Wolff points out, tuberculosis now contributes such a small proportion of the total deaths, that if every single death from tuberculosis in the 0-1 year age group in Berlin could be prevented, the infantile mortality rate would drop only from 78 to 76.4 per 1,000. A fall in the infantile mortality rate from all causes, which Calmette asserts to be one of the main benefits of B.C.G. vaccination, is difficult to interpret for the same reason. Moreover, if B.C.G. is so effective in this respect, why is it, Berghaus[5] asks, that the infantile mortality in France has risen during the past two or three years? If a definitive answer is to be obtained, we venture to assert that nothing short of a direct *ad hoc* investigation, with the most careful control of all factors, will suffice.

Thirdly, "Even if it should be firmly established that B.C.G. was capable of producing an appreciable degree of immunity, would it be wise to advocate its general adoption?" Professor Neufeld[6] is speaking for most students of tuberculosis when he says that the whole epidemiology of this disease, as well as the course of particular cases of tuberculosis, is determined far more by the natural constitutional resistance of the individual than by the acquisition of specific immunity, as taught by von Behring and Römer. It is surely for

[5] Berghaus, W.: *Deut. med. Woch.*, 1931, lvii, 95.
[6] Neufeld, F.: Ibid., 1930, lvi, 1599.

this reason that, in the absence of all measures designed to increase specific immunity, the mortality rate from tuberculosis in this country in the 0–1 year age group fell during the thirty years 1898–1927 by no less than 86 per cent. (Dow and Lloyd[1]). Improved housing, economic and nutritional conditions, together with the gradual improvement and increasing pasteurization of the milk supply, have probably all played a part in this reduction. In 1929 only 1.4 per cent. of the infantile mortality was due to tuberculosis, and the chances against dying from tuberculosis during the first year of life were about 1,000 to 1. In the face of such highly successful measures is there any justification for advising the vaccination of every infant with B.C.G.? When it is considered that whatever protective effect B.C.G. may have probably wears off in the course of a year or two—Professor Calmette is now recommending revaccination at 3, 7, and 15 years—and that for a month or longer after vaccination the infant must be carefully isolated from every possible source of tuberculous contamination, it will probably be agreed by most workers that any general adoption of vaccination would be highly inexpedient. The case with infants who are born of tuberculous parents, and who must unavoidably be exposed to frequent and often heavy infection during the first few months of life, is on a different footing. We are strangely ignorant of the real risk incurred by such children, but it is legitimate to assume that it will be greater than that of children reared by healthy parents. The prophylactic vaccination of such infants might conceivably convey sufficient immunity to turn the balance in favour of the child, and it is for such a class that vaccination should be reserved. Even then it should be employed only *faute de mieux*; the correct way to deal with these infants is to remove them to a healthy environment, as is being carried out under the highly successful Grancher system in France.

If it should be considered desirable, under these limited conditions, to give B.C.G. a trial, it is of the first importance that it should be made on a definitely experimental basis. The indiscriminate use of the vaccine by isolated practitioners will never enable us to assess its worth correctly. To judge the value of a therapeutic measure on clinical grounds alone is sufficiently difficult; to judge the value of a prophylactic measure on clinical grounds alone is well-nigh impossible. The advantage conferred by vaccination is not likely to be great, and the only way of assessing the 5, 10, or 20 per cent. increase in resistance which it may produce is to perform the experiment in such a way that the resulting figures are really suitable for statistical analysis. If an experiment was to be conducted on cattle by the Ministry of Agriculture, and on children by the Ministry of Health or the Medical Research Council, the details of the experiment being determined by a committee appointed by these bodies comprising one or more bacteriologists, statisticians, tuberculosis and children's specialists, and veterinarians, it might be possible in the course of five or ten years to reach some conclusion as to the real value of B.C.G. vaccination. Nothing short of this is likely to extricate the problem from the welter of confusing statements which at present surrounds it.

NATIONAL COLLECTION OF TYPE CULTURES

The establishment of the National Collection of Type Cultures of Bacteria and the issue of the first catalogue in 1922 marked an important step in the development of bacteriology in this country. Before that date there was no official repository for bacterial cultures. Individual bacteriologists kept their own collections, but there was no organization for the permanent preservation of pure cultures and for the supply of correctly labelled cultures to laboratory workers who required different species of bacteria for teaching purposes or for comparison with recently isolated strains. Since this work was undertaken at the Lister Institute under the supervision of Professor Ledingham and Dr. St. John-Brooks the museum has grown to such proportions that it now contains more than three thousand different strains of micro-organisms. The demand for the cultures has increased to such an extent that more than five thousand cultures are being distributed to workers throughout the world each year. The latest catalogue[1] is an enlarged and revised edition of the list published in 1925. The different strains are catalogued alphabetically, each entry giving details of the type, group, or variety of the strain, the name of the person and institution supplying the strain, and in some cases particulars of the source from which the micro-organism was isolated. An attempt has been made to reduce the numbers of organisms appearing under the general heading of "bacterium" or "bacillus" by segregating some of the more natural groups and entering these as separate genera. This arrangement imposes a little inconvenience on those who are still accustomed to refer to bacteria by their old-fashioned names. For instance, *B. typhosus* must now be looked for as *Salmonella typhi*, and *B. tuberculosis* as *Mycobacterium tuberculosis*. In all such cases, however, ample cross-references are given for the benefit of those more familiar with the older system. The Medical Research Council expresses the hope that this new edition of the catalogue will tend to direct the attention of bacteriologists in this and other countries to the continued need for the deposition of strains of bacteria and fungi for maintenance and reference in this collection.

THE CASSEL HOSPITAL

The report[2] of the director of the Cassel Hospital for the year ending December 31st, 1930, deals as usual only with patients who have been discharged for at least one year. A very interesting feature of the present record is the unusual proportion of successes in the treatment of obsessive-compulsive conditions. Of seven patients suffering from a condition of this kind, three are now well, after six and ten months' treatment respectively, while two improved considerably. This

[2] The Cassel Hospital for Functional Nervous Disorders, Swaylands, Penshurst, Kent. Ninth Annual Report to the Committee from the Medical Director.

is so much better than the previous experience of the director or anyone else with this type of patient, that it would be unwise to regard it in the meantime as of definitely good omen in a condition that has hitherto, in the vast majority of instances in adults, borne a poor prognosis ; but it does point to a hope of more frequently successful psychotherapy in skilled hands than in the past. It is notable also that the two patients who did not improve were much older than the others, being 45 and 56 respectively, which are rather advanced years for the intensive psychotherapy of any kind of neurosis. Of the patients with anxiety psychoneuroses, two are singled out for brief description. One of them was a medical student, and the point of interest is that the treatment was largely indirect, by way of teaching him the principles of psychopathology, illustrated as far as possible from his own life, since his attitude rendered a more usual technique impossible. He made a good recovery, although his symptoms were unusually severe. It is the experience of at least one authority that medical students and doctors as a class give better results with psychotherapy than patients in any other occupation. It would be interesting to know why. The student in question was unusually intelligent ; but this is not the only factor in such cases, since it is not always present. Turning to another part of the report we note that after three years of freedom from incidents of the kind, there have been several suicides and genuine suicidal attempts. Those which occurred in patients with phobias and anxieties are of special theoretical interest. It is perhaps not very helpful to speak of them as having had a " concealed psychosis." There has, however, been a tendency for the Cassel Hospital to be put in the position of receiving more and more difficult cases as time goes on, and for those who send patients to forget that this hospital was intended primarily for the treatment of psychoneuroses. The difficulty resides partly in the length of the waiting list, which means a most undesirable delay, during which time the less seriously ill become worse, or go elsewhere, or recover spontaneously. The waiting list tends to accumulate patients who should not go to the Cassel Hospital at all. Thus, the 178 patients mentioned in the report included 14 with psychotic depressions and 12 cases of schizophrenias, the great majority of whom should not, on any consideration, have been sent there. The report continues to fill a unique position, in this country at least, as a detailed record and follow-up of results in the psychological treatment of psychoneuroses.

PSYCHOLOGY AND THE WORKER

The National Institute of Industrial Psychology opened its doors at Aldwych House the other day to a company of guests who were permitted an inspection of the various works which Dr. C. S. Myers and his staff are carrying out. To those who recall the early days of the institute, with its modest ventures into industrial psychology (such as an inquiry as to why cups get broken in teashops), it was surprising to find how large a field it now covers, and how far it has gone towards the complete " psychography " of the worker. Demonstrations were given in different rooms of the ideal lay-out and production-planning of a factory from the psychological standpoint ; of the methods for increasing the output of those engaged in repetitive tasks ; of research into the mental abilities and processes involved in the operation of assembling ; of the effects of ventilation and lighting conditions on the worker ; of the part which awareness of rhythm plays in certain tasks, and its association with muscular skill (showing, for example, how the typist, with an uncanny number of words a minute to her credit, drops into error or slowness when the syllabic rhythm disappears and she is confronted with some unaccustomed juxaposition of letters) ; of the tests required for the selection of shorthand-typists, telephonists, sorters, packers, and of others whose avocations demand great manual dexterity ; and, finally, of the degree of difficulty in changing from one activity to another. It was also shown how tests are employed for such things as colour discrimination, and how unconscious emotional reactions can be recorded by changes in the electrical conductivity of the body as shown by a psychogalvanometer. In one room a very interesting demonstration was given of tests for motor-driving. The subject sat in a dummy car with all the controls—accelerator, steering wheel, and brake—at his hand and foot. Everything, including the noise, was as in a car, except that it was not the car but the landscape which moved. The room was darkened, a little table with miniature trees and other objects was made to revolve, and this cast a shadow on a paper screen in front of the driver, so that he got an illusion of roads opening out and dividing in front of him. It was stated that this realistic device afforded a means of measuring the reaction time and the judgement of distance. It occurred to us that those unfortunate people whose driving licence is suspended might get all the thrill and pleasure they want from some such expedient, without being inconvenienced by police or by cars coming the other way. Perhaps the greatest service which the institute is rendering is in respect to vocational guidance. Dr. Angus Macrae showed a number of case-studies of secondary school boys, each boy's characteristics being indicated in the form of a " psychographic profile." The institute, financed by grants by the Carnegie United Kingdom Trust, has recently carried out an experiment in the vocational guidance of six hundred elementary school children. In addition, last year over four hundred private fee-paying persons were examined and advised as to future occupation. Among cases which it has been possible to follow up after three years, it has been found that 85 per cent. have justified the institute's predictions, either by making good in the occupation which it advised, or by comparative failure in some other occupation which the institute said was unsuitable.

WILLIAM STEWART HALSTED

Dr. W. G. MacCallum has paid a handsome and ungrudging tribute[1] to the merits of that distinguished surgical investigator and operator who, in the words of Dr. W. H. Welch, was the creator of a Halsted school of surgery at Johns Hopkins University in Baltimore. William Stewart Halsted was one of the group of four—the others being Osler, Welch, and Kelly—who, when

[1] *William Stewart Halstead, Surgeon.* By W. G. MacCallum. Introduction by Dr. W. H. Welch. Baltimore: The Johns Hopkins Press ; London: Milford, Oxford University Press. (12s. 6d. net.)

it was decided to complete Johns Hopkins University by the addition of a medical school and hospital, were charged with the duty of organizing it. Their success is world-known, and the valuable investigations carried out in the laboratories of the school have conferred lustre upon it and its staff. Before he joined Dr. Welch at Baltimore in 1886, Halsted had had a successful and strenuous career in New York, where he not only operated at five hospitals, but conducted a most successful surgical class, which attracted students in such numbers that the authorities of the hospital schools of New York were seriously perturbed. Such sustained and almost feverish activity had its consequences, and Halsted fell a victim to cocaine, then newly discovered. He not only investigated its properties and devised the method of infiltration anaesthesia, but he unfortunately became an addict. The dangers of cocaine were then little known, and it is no shame on Halsted that he succumbed, but rather a great tribute to his strength of character that he ultimately succeeded in curing himself of the habit. The struggle was hard and prolonged, involving more than one sojourn in an institution for such cases. Halsted is best known in this country for his operative work on cancer of the breast, hernia, and goitre, but his greatest interest was in the laboratory rather than in the operating theatre. The process of union in wounds, and the circumstances which hindered or promoted primary union, were subjects of repeated experiments on animals, from which he learnt valuable lessons, one of the chief of which was that undamaged tissue, such as normal peritoneum, can dispose of pathogenic micro-organisms which would set up a virulent growth in the presence of damaged or dead tissue. Unlike Osler, Halsted does not seem to have been distinguished by geniality. His wit was caustic; Dr. MacCallum frankly admits that "no one was ever at his ease with him except his close friends," and in another passage refers to his indulgence in *Schadenfreude*. Evidently his personality was a complex one; he was so fastidious as to send his shirts from Baltimore to Paris to be laundered, but he frequented prize fights in Baltimore at a time when such exhibitions were anything but refined. These were perhaps the eccentricities of genius, and it is beyond question that Halsted was a great surgeon and surgical pathologist.

INTERNATIONAL CONGRESS OF HISTORY OF SCIENCE

The second International Congress of the History of Science and Technology, of which previous announcements appeared in our issues of January 31st and May 9th, will be opened by Mr. Lees-Smith, the President of the Board of Education, on Monday, June 29th, at the Science Museum, South Kensington, which will be the headquarters of the congress during the week. A reception will be given by the president, Dr. Charles Singer, and Mrs. Singer, at 9 p.m., at the Royal Society of Medicine. On Tuesday, Mr. G. N. Clark of Oxford, late editor of the *English Historical Review*, will open a discussion on the sciences as an integral part of general historical study, and a discussion, under the chairmanship of Dr. Welch of Johns Hopkins University, will be held the same morning on the teaching of the history of science. On Wednesday there will be an excursion to Cambridge. On Thursday a discussion will be held on the historical and contemporary interrelationship of the physical and biological sciences, introduced by Professor Baas Becking of Leyden and Dr. Joseph Needham, and the final discussion will be held on Friday, on the interdependence of pure and applied science. There will be a banquet in the evening at the May Fair Hotel. On Saturday an excursion will be made to Oxford, and the Provost of University College, London, will entertain members at an Independence Day luncheon, when the American Ambassador, General Dawes, has promised to be present. Special visits will also be made to the Royal Botanic Gardens, Kew, and the Royal Observatory, Greenwich, to Barbers' Hall, and to the Royal College of Physicians. Further information can be obtained from the honorary secretary, Mr. H. W. Dickinson, Science Museum, South Kensington, S.W.7.

PATHOLOGICAL MUSEUM, EASTBOURNE

Members who wish to send exhibits to the Pathological Museum in connexion with the Annual Meeting of the British Medical Association at Eastbourne should forward their particulars to Dr. E. A. Fiddian, Avenue House, The Avenue, Eastbourne, without delay, as these are necessary for the catalogues, and cannot be included in them unless they reach the Honorary Secretaries by June 30th at the latest. Acceptable material falls under the following heads: (1) exhibits bearing on discussions and papers to the various Sections (as set out in the *Supplement* of June 6th); (2) specimens and illustrations relating to any recent research work; (3) instruments relating to clinical diagnosis and pathological investigation; (4) individual specimens of special interest, or a series illustrating some special subject.

ROYAL SOCIETY OF MEDICINE

In accordance with the will of the late Dr. Robert Thomas Nichols, the Royal Society of Medicine offers, every three years, a prize for the most valuable contribution by a British subject towards the discovery of the causes and the prevention of death in childbirth from septicaemia. At the last meeting of the council of the society the Nichols prize was awarded to Dr. John Smith of Aberdeen, and to Dr. R. R. Armstrong and Mr. H. Burt-White (a conjoint contribution) of St. Bartholomew's Hospital. At the same meeting the Jenner medal was awarded to Dr. T. H. C. Stevenson of Somerset House. This medal is awarded to persons whose work has been pre-eminent in the prevention and control of epidemic disease.

We regret to announce the death of Baron Shibasaburo Kitisato, one of the pioneers of bacteriology in Japan, and founder of the Governmental and Kitisato institutes for infectious diseases in Tokio.

The council of Epsom College will shortly elect a girl to a St. Anne's Scholarship of £120 a year. Candidates must be not less than 9 years of age on July 29th next, and must be orphan daughters of medical men who have been for not less than five years in independent practice in England or Wales. Application must be made by July 2nd, on a form to be obtained from the secretary of the College at 49, Bedford Square, W.C.1.

HARVEIAN SOCIETY'S CENTENARY

CELEBRATION AT ST. BARTHOLOMEW'S

The celebration of the centenary of the Harveian Society of London began with a largely attended meeting at St. Bartholomew's Hospital on the afternoon of June 11th, when Dr. RAYMOND CRAWFURD delivered the address on "The place of medical societies in the progress of medicine" which was printed in our last issue (p. 1036). Sir THOMAS HORDER, president of the society, was in the chair, supported, in addition to those whose names appear below, by Lord Dawson of Penn, Sir StClair Thomson, Sir William Hale-White, Sir John Rose Bradford, Dr. Herbert Spencer, and Dr. G. de Bec Turtle.

Sir HUMPHRY ROLLESTON, in proposing a vote of thanks to Dr. Crawfurd, said that there could hardly be a more fitting setting for the centenary celebration than St. Bartholomew's Hospital, where Harvey was a physician. Harvey had tried to knit together the Royal College of Physicians and the hospital beyond any chance of severance, and to this day no one was appointed physician to the hospital unless nomination had been made by the Royal College. One of Dr. Crawfurd's predecessors as registrar of the Royal College of Physicians, Sir George Elliott, about the year 1650 went to pay his respects to Harvey, then in retirement, and found that Harvey had written a book. After much hesitation on Harvey's part, Elliott obtained permission to publish this monograph, and went away like Jason carrying the Golden Fleece. Elliott remarked that the more Harvey's books were read and admired the more reluctant he seemed to have them published, in strong contrast with some who made a great display of their work.

Sir THOMAS HORDER then presented medals specially struck for the centenary to Dr. D. Elliot Dickson, representing the Harveian Society of Edinburgh, and Dr. W. H. Welch, Professor of the History of Medicine at Johns Hopkins, representing the Harveian Society of New York.

Dr. ELLIOT DICKSON, in returning thanks, said that he was proud to represent the Edinburgh society, and also proud as a Scotsman to have heard Dr. Crawfurd's reference to the Royal Medical Society of Edinburgh.

Professor W. H. WELCH said that all members of the New York society would heartily appreciate the generous words in which Dr. Crawfurd had referred to its activities. The principal function of that society was in its lectureships, perhaps six or eight lectures being delivered during the year in the general field of scientific medicine, and it was obvious that there was no name in history which could be more appropriately used as the sponsor of such a society than that of William Harvey. Dr. Welch handed to the president an illuminated scroll on behalf of the New York Harveian Society, inscribed with cordial greetings on the occasion of the hundredth anniversary, and expressing appreciation of the significance of continuous corporate existence for so long a period:

"An achievement so signal bears witness to the serviceableness to its members of any association. In medicine it bears evidence, furthermore, to the success of its function in the maintenance of a high standard of scholarship and its usefulness in the dissemination of learning."

Before the company separated a number of Harvey relics, displayed in the hall, were indicated and described by Mr. Geoffrey Keynes.

CENTENARY DINNER

The society's centenary dinner, given by Mr. George Buckston Browne was held on the evening of June 12th in the magnificent hall of the Grocers' Company in the City of London. Among those beside the president, Sir Thomas Horder, were H.R.H. Prince Arthur of Connaught, Professor W. H. Welch of Johns Hopkins University, Lord Dawson, President of the Royal College of Physicians, the Master of the Grocers' Company and the Master of the Society of Apothecaries, Dr. Elliot Dickson, president of the Edinburgh Harveian Society, Sir Farquhar Buzzard, Regius Professor of Medicine at Oxford, Mr. J. F. Cameron, Master of Caius College, Professor Blair Bell, President of the British College of Obstetricians and Gynaecologists, Surgeon Vice-Admiral Sir Arthur Gaskell, Dr. H. B. Brackenbury, Chairman of Council of the British Medical Association, The Rev. T. P. Conyers Barker, Vicar of Hempstead, Sir D'Arcy Power, Dr. Henry S. Wellcome, and the presidents of kindred medical societies.

After the loyal toasts had been honoured, the PRESIDENT welcomed Prince Arthur of Connaught as a newly admitted honorary member of the society, and presented to him a commemorative bronze medal. HIS ROYAL HIGHNESS then proposed the toast of "Prosperity to the Harveian Society of London." He felt it a great—though perhaps an "irregular"—honour to be admitted to membership of the society, in company with Professor Welch, the doyen of the medical profession of the United States. As chairman of the Middlesex Hospital he welcomed the opportunity of being present to congratulate the society on its centenary, and recalled that he was an honorary freeman of the Grocers' Company, which had many links with medical science. The PRESIDENT, in replying to the toast, thanked Prince Arthur for the compliment he had paid the society, which was appreciated all the more because of his intimate association with medical progress as the working head of a great hospital. In expressing gratitude to the Master and Wardens of the Grocers' Company for the loan of their beautiful hall for that dinner, he mentioned that three of Harvey's brothers were Grocers. The arrangements for the centenary had been most admirably carried out by the indefatigable treasurer, Dr. Turtle, and the honorary secretaries, Mr. Wakeley and Dr. Cove-Smith, and all were indebted to Mr. Buckston Browne for his generous hospitality that evening. Sir Thomas Horder recalled the names of some of his famous predecessors in the presidential chair, and ended with an eloquent tribute to the work and inspiration of William Harvey.

"It is always difficult for us to speak of William Harvey in anything like moderate language. He is so easily the central figure in our annals, and the founder of scientific medicine in this country. As Caesar appeared to Cassius in relation to the Roman Republic, so Harvey appears to us in relation to British medicine, but without the stigma imputed to the great Roman by his lean and hungry conspirator: '. . . he doth bestride the narrow world like a Colossus, and we petty men walk under his huge legs and peep about and find ourselves dishonourable graves.' Harvey did a much greater thing for medicine than to establish beyond all doubt the physiological principles governing the circulation of the blood. He introduced rational and scientific methods into the chaos of empiricism, speculation, and wild hypothesis. This reference to a principle does not detract from the momentous value of Harvey's great discovery: it rather enhances it, in that this discovery exists for all time as a model of what may be achieved along the lines, and following the principles, which Harvey laid down."

The health of the visitors was proposed with graceful references to individual guests by Sir STCLAIR THOMSON. This feast, he said, gave an opportunity for the mingling of men of different occupations, as well as of men working in different branches of the same profession. Harvey, a man of wide humanity and culture, would have welcomed this occasion, for had he not exhorted his brethren to "dwell together in loving friendship"? Professor WELCH, in response, made a charming and spirited speech of appreciation for the way in which "such things are done in London." He regarded

centenary celebrations as very valuable and interesting things, which appealed to him particularly as contributions to the history of medicine. Lord DAWSON, who also replied, spoke of Professor Welch as a citizen of the world, exemplifying the unity of purpose of the English-speaking medical profession. He himself, during his visit to Canada and the United States last year to attend the Annual Meeting of the British Medical Association in Winnipeg, had observed the inexhaustible energy and enthusiasm of their octogenarian guest. On behalf of the Royal College of Physicians, with its long and intimate associations with Harvey, Lord Dawson congratulated the society on attaining its hundredth year.

PILGRIMAGE TO THE HARVEY TOMB

The final event of the celebrations took the form of a pilgrimage to the tomb of William Harvey at Hempstead Church in Essex, near Saffron Walden. A party of about sixty, headed by Sir Thomas Horder, Sir D'Arcy Power, Sir StClair Thomson, Dr. Herbert Spencer, and Professor Welch, journeyed by road from London on the morning of Saturday, June 13th. At Hempstead Church a brief service was held, and the Bishop of Colchester gave an address. Harvey, he said, was a man of whom any age and country would have been justifiably proud. The more a good life and good work was made known, and the more a brotherhood such as the Harveian Society grew, the better for humanity. In that church lay the mortal remains of the great doctor, and a suitable monument had been erected there in honour of one whose fame was world-wide. He thanked the society for presenting to the church, in commemoration of the present occasion, a beautiful silver platen, to be used with the Elizabethan chalice belonging to the church, the original platen which went with it having been lost. The new platen bore the crest of the Harveian Society and the date of its foundation and of the gift. It was also good news to Hempstead that the Harveian Society proposed to undertake the reconditioning and rehanging of the church bells when the tower was rebuilt, and to give a new bell to celebrate the event. The old bells, now in a bell-shed in the churchyard, were dated, one of them 1520 and the other 1575. For the rebuilding of the tower the sum of £2,700 was in hand or promised, and a further £3,000 was required. Donations were still coming in, and those responsible for the church were more indebted than they could express to the medical profession, who had shown that it was a labour of love to do all they could for the preservation of the temple which contained the Harvey shrine. Finally, said the bishop, they had assembled that day, not merely to praise famous men of old, who rested in peace and whose works followed them, but also to thank God for the work of the medical profession. Doctors of to-day went about doing good to the bodies and minds and souls of men. In every age they were among the world's best philanthropists and most sacrificing missionaries. Very few men had more opportunities of service to their kind. The healing and relief of suffering was a godlike task, and he trusted that there would never be wanting in this dear land physicians of like spirit to William Harvey, who employed heart and brain in the service of their fellow creatures and for the glory of God.

After the address Sir Thomas Horder, president of the society, accompanied by Dr. de Bec Turtle, Mr. Cecil Wakeley, and Dr. R. Cove-Smith, brought the platen to the altar, where it was dedicated by the Bishop. Subsequently the visitors inspected the Harvey Chapel and other objects of interest in the church, and even descended into the vault, where rest the coffins of various members of the Harvey family. The pilgrims were entertained to lunch in the vicarage garden, and on the return journey a halt was made at Rolls Manor, Epping Forest, where seven generations of Harveys lived, and which is now in the possession of Lady Lloyd, widow of General Sir Francis Lloyd, the Lloyds about a hundred years ago becoming related to the Harveys by marriage. In a room specially built for the purpose are shown the Harvey portraits, including William Harvey, with his father, six brothers, and sister or sister-in-law. Sir D'Arcy Power gave a brief account of the Harvey family. Harvey, he said, was known elsewhere as an acute thinker and able administrator, but here in the home of his family he was revealed in a domestic role—for singularly strong bonds of affection united the Harvey family—and also as a connoisseur and collector of objects of art. Some of the Harveys made fortunes in business, and others, notably Admiral Sir Eliab Harvey, gained distinction in the national service. Before the party returned to London Sir Thomas Horder expressed the thanks of everybody for the charming hospitality of Lady Lloyd.

Nova et Vetera

DOCTORS' BILLS

Mr. N. F. Ticehurst, F.R.C.S. (St. Leonards-on-Sea), writes:

With reference to the notes on ancient doctors' bills under "Nova et Vetera" in the *Journal* of October 4th, 1930, it occurs to me that you might like to print the accompanying account. I found it a year or two ago while going through the miscellaneous documents in the parish chest at Sedlescombe, near here, to sort and calendar them for the present churchwardens. The date is slightly anterior to any you quote, and, though not written in full, the year is 1689, as the writing corresponds with other documents of that period in the collection, and John Huckstep was overseer at that time. Of John Martin I can learn nothing, but perhaps you have records that might reveal something of him. I should hazard a guess that he lived at Battle, on which town Sedlescombe has always been dependent for its medical services. Martin has always been a well-known name there.

Then receed of Jon Huckstepe Ouerseare The sume of one pound four shillings and eight pence being in full of this Bill for Phisicke administred to Ann Blatcher and Jon Henlly of the parrish of Sedlescombe: Receed p me Jon Martin 1li. 4s. 8d.

This bill, discovered by Mr. Ticehurst, is of interest as carrying further back than did that of Fairclough (*British Medical Journal*, 1930, ii, p. 576) the evidence of expenditure on the medical care of the poor under the Poor Law of Elizabeth. The bill is typical of the pharmacy of the time, and needs no comment except some explanation of the term "Apozem." This, according to the *New English Dictionary*, is an obsolete word meaning a decoction or infusion. Mr. Ticehurst is to be congratulated on his find, and our readers are much indebted to him.

JOHN HAYGARTH OF CHESTER

Dr. George H. Weaver of Chicago[1] has recalled to his *colleagues of the Society of Medical History of that city* the name and fame of Dr. John Haygarth of Chester (1740–1827), who has not been forgotten in the land of his birth and death.

The late Dr. John Elliott of Chester contributed to our pages in 1913 (vol. i, p. 235) an excellent sketch of Haygarth's career, illustrated with eight illustrations, and a succinct account of him is also to be found in the *Dictionary of National Biography*. Even those recognitions of Haygarth's importance as a pioneer in public health, epidemiology, and medicine leave something to be desired in publicity, and we welcome, therefore, the fuller account of him, of which Dr. Weaver has sent us a reprint.

Dr. Weaver quotes from Dr. Elliott's "Nova et Vetera" article, and agrees with his expression of opinion that the work of Haygarth had not yet received adequate recognition. He was, as Dr. Elliott said, a medical pioneer who explored more than one path of advance in medical science. His work on inoculation for small-pox was eclipsed by Jenner's discovery of vaccination, but in other directions he made notable advances. His career is particularly interesting to Americans because of his correspondence with Benjamin Franklin and with physicians in the United States.

His well-known "Letter to Dr. Percival on the Infectious Fevers," and his address to the College of Physicians on the American Pestilence, seem to have irritated the thin skin of one Dr. Charles Caldwell, who wrote "Vindicating the Right which the Faculty of the United States have to Think and Decide for themselves respecting the Diseases of their own Country, Uninfluenced by the Notions of Physicians in Europe." But it was not only in America, in 1802 and later, that medical controversy was disfigured by irrational violence.

Australia

[FROM OUR CORRESPONDENT IN SYDNEY]

The Royal Australasian College of Surgeons

The fourth annual meeting of the College of Surgeons of Australasia (which includes New Zealand) was held in Sydney during the four days ending April 2nd, 1931. The period was fully occupied with business, lectures, and demonstrations, no time being allotted officially for social functions. There was a good attendance of members. Perhaps the most important business was the announcement that a Royal Charter had been granted to the College, which will henceforth be known as the Royal Australasian College of Surgeons. The adoption of this name will preclude the possibility of confusion with the Colleges of the United Kingdom and of the United States. The journal of the College, which has hitherto been known as *The Journal of the College of Surgeons of Australasia*, will in future bear the title *The Australian and New Zealand Journal of Surgery*. For a young College this journal is a very creditable production; its general appearance and style have already evoked favourable comment from overseas. Possibly the granting of the Royal Charter will assist in the firmer establishment of an *esprit de corps* and a jealous pride in the reputation of the College which will be reflected in the work of the Fellows and their writings, with further improvement in the journal. The College is so young that it has barely had time to develop an individuality of its own, the influence of the British and American Colleges being still apparent. No doubt in the course of a few years the Royal Australasian College of Surgeons will be as typical of the Dominions as other Australian and New Zealand institutions; in common with these it will, of course, bear the marks of the influence of older Colleges, especially those of the United Kingdom.

An Association of Physicians

An event of some importance during the year 1930 was the formation of the Association of Physicians of Australasia (including New Zealand). The founders set out with the object of moulding the association on the lines of the Association of Physicians of Great Britain and Ireland. The stated purpose of the Association is "the advancement of internal medicine and the promotion of friendship among physicians." Meetings will be held twice a year in one or other of the capital cities. At these meetings members and visitors will contribute scientific communications on various subjects. An express rule of the association is that no papers shall be read at the meetings, and no reports of the proceedings shall be given either to the lay or to the medical press. In regard to qualifications for membership the following rules are laid down in the constitution. The association "shall consist of ordinary members, not more than ten associate members resident in New Zealand, and honorary members. It shall at first contain not more than seventy ordinary members, who shall be physicians actively engaged in the teaching of medicine, men of distinction in medicine and the allied sciences, and physicians recognized by the council as eligible."

Sir Henry Maudsley and Dr. R. Scot Skirving have been elected honorary life members of the association as a tribute to their services to medicine in Australia. The president of the association is Sir Richard Stawell, the honorary secretary Dr. S. V. Sewell, and the honorary treasurer Dr. S. O. Owen. The following have been elected members of the council: Drs. C. B. Blackburn, E. W. Fairfax, A. W. Holmes à Court, H. H. Turnbull, K. Hiller, S. A. Smith, H. J. Ritchie, L. S. Latham, M. D. Silderberg, C. H. Kellaway, S. F. Hone, C. T. Ch. de Crespigny.

Sydney University

The opening of university activities this year marks the commencement of a new era in the teaching of medicine at Sydney. The whole curriculum for the teaching of students of the fourth, fifth, and sixth years has been revolutionized, and a system has been evolved which is unique in Australia and probably in the world. The system is in accordance with the scheme outlined by Professor C. G. Lambie, the recently appointed Bosch Professor of Medicine, in an address which he delivered in October, 1930 (published in the *Medical Journal of Australia* of January 31st, 1931). It is at present in operation, and gives every prospect of success. One of the most important objects is the correlation of the various arts, crafts, and sciences which go to make up the science of medicine, so that these may be moulded into one and presented to the student as a whole. The watertight compartments of the various branches of medicine are eliminated, and the special subjects are presented, not by means of a series of lectures over a given period, but by lectures delivered at such times as best fit in with the general scheme. For example, in his fourth year the student receives instruction in the pathology of the organs of respiration; at the same time lecturers in medicine and surgery discuss disturbances of function of these organs, the oto-rhino-laryngologist the upper respiratory passages; the general therapeutics of the diseases of the organs of respiration are dealt with, and instruction is given in the materia medica and the prescription of the drugs

[1] *John Haygarth, Clinician, Investigator, Apostle of Sanitation.* By George H. Weaver, M.D.Chicago. Reprinted from the *Bulletin of the Society of Medical History of Chicago*, 1930, iv, 156.

employed. During the fourth year students have lectures from the dermatologist on the general examination of the skin, and during the fifth year lectures on specific diseases of the skin, the dermatological manifestations of systemic diseases being studied at the appropriate time. The dermatologist assists in the combined attack on the subject of syphilis, by paediatrician, physician, surgeon, and neurologist, and deals with allergic skin manifestations when the lecturers in medicine are discussing allergy. A good illustration of correlation of subject-matter is that instruction concerning infection is given by the bacteriologist, while the pathologist discusses inflammation and repair, the surgeon wounds and sepsis, the physician pain and fever, and the pharmacologist antiseptics and analgesics. All teaching in medicine and surgery is given from a clinical standpoint. Lectures in the fourth and fifth years, save those in pathology and bacteriology, are delivered at the Royal Prince Alfred Hospital, the Children's Hospital, or the Coast Hospital. With the patients before him the lecturer not only illustrates the points of his argument, but also demonstrates how by a consideration of the abnormal individual and by the study of pathology, a knowledge of disease is achieved and increased, provided there is as a basis an understanding of physiology and anatomy. The fourth year is devoted to the teaching of pathology and bacteriology, general semeiology, and general therapeutics; in the fifth year nosography, special semeiology, and specific therapy are dealt with; in the sixth year chief emphasis is laid on a consideration of differential diagnosis and prognosis. Although no lectures in pathology are given after the end of the fourth year, it is intended to appoint from among the students pathological clerks whose duty it will be to make necessary pathological investigations of patients in the wards of the hospitals. The student will thus be forced to realize that pathology cannot be divorced from a study of medicine. In the final year the teaching is entirely devoted to work in the wards. Throughout the three years the students are given ample opportunity for clinical work, their clinical teaching being facilitated by the formation of smaller classes. The sequence of the various courses of instruction throughout the curriculum during these last three years follows a definite and carefully thought-out plan. Disturbances of all functions are dealt with system by system during the fourth year, with the exception of those of the genito-urinary system, which is studied in the fifth year, when instruction is given in gynaecology followed by obstetrics. In the fifth year, as soon as the lectures on infectious diseases have concluded the study of preventive medicine is commenced. Medical jurisprudence and medical ethics are dealt with in their natural place at the end of this year.

The adoption of the new system has necessitated the appointment of new lecturers and tutors. The subjects of therapeutics and materia medica have been brought into the department of medicine, and the first assistant to the professor of medicine lectures on general therapeutics and applied pharmacology. A building which will contain the various departments concerned with the work of the fourth and fifth years, and in which all lectures will be given, is to be erected in close proximity to the Royal Prince Alfred Hospital. Thus clinical material will always be readily available. An important feature in the design of the building is the nearness of the lecture theatre to the pathological museum. Large laboratories, fully-equipped for research in every branch of medicine and surgery, will be provided. When the suggestion was made for the erection of this structure and for the institution of the new system of teaching, the fear was expressed that the clinical schools at Sydney and St. Vincent's Hospital might be abolished, but this is not contemplated.

Scotland

The Blind in Scotland

The annual report of the Royal Blind Asylum and School, Edinburgh, shows that upwards of 2,000 blind persons have been educated or employed by the institution since its foundation. Although the industrial department has felt the prevailing trade depression, this has to a certain extent been met by the introduction of new employments for the blind. The accommodation for the technical training branch has been extended during the year by the transfer of the administrative department to a new building at Gillespie Crescent, Edinburgh. There are now twenty-two blind persons under training in the workshops of West Craigmillar, and ninety in those at Gillespie Crescent. During the year under review the sales of material manufactured by beneficiaries amounted to £34,483. During the year £440 had been expended on grants to blind persons in various parts of the country, while a sum of £500 had been set aside for this purpose in the current year. The income from ordinary subscriptions had been £7,608, as compared with £8,097 in the preceding year. The Scottish National Institution for Blinded Sailors and Soldiers had admitted three additional men for training during the year, and had now seven men under training at Newington House. In the Newington House workshops thirty-seven ex-service men were employed, and in a workshop in Glasgow twenty-two were now resident in Men trained at these institutions were supervised by the various parts of the country, and were supervised by the institution. All these men received an allowance from the institution of not less than 10s. per week in addition to their pensions.

The Scottish National Federation for the Welfare of the Blind held its meeting on June 11th and 12th in Dundee. Mr. James Balfour, who presided, said that the facilities which were now available for blind people in this country were in advance of those in any other country. There were roughly 9,000 blind people in Scotland, of whom approximately two-thirds were over 50 years of age. Dr. W. G. Sym (Edinburgh) read a paper on the myopic child. In order to educate such a child without doing further harm to the eyes, he said that the first point was that the child must wear proper glasses constantly. He did not agree with the plan of associating the myopia class with the blind school; he was convinced that the training for myopics should stand by itself. A paper was contributed by Mr. William Stone, superintendent of the Royal Blind Asylum, Edinburgh, dealing with the welfare of the blind under the Local Government Act, 1929. He referred to the fact that infantile blindness was decreasing, and it might be that in the course of a generation a baby blind from birth would be a rarity. Technical training for the blind was a costly process; and it was unfortunate that so many of them could not be trained for anything. It had always been considered that the natural outlet for the capacities of the blind lay in the use of their hands, but this was not really true; only a small number of blind people were really gifted as craftsmen. Others might become good craftsmen by dint of hard work and patient teaching, but people who worked with blind children saw their difficulties in dressing, etc. It was generally supposed that the blind had a delicate sense of touch, but the sense of touch in the average blind person was rather less acute than in those who saw well. In the future, when these facts were better known, more would be done for the blind by putting them into commercial life rather than condemning them to handwork, which was the least suitable kind of

work for them. In this direction much more had been successfully done in the United States than in this country.

Gilgal Hospital, Perth

This hospital, which has been designed and erected by the directors of James Murray's Royal Asylum, Perth, is a self-contained block of forty beds on an adjacent site. It is intended solely for voluntary patients, especially for those whose malady is slight or of short duration, and who may be apprehensive of possibly harmful or painful contacts with invalids of a more confirmed or different type. The property (Gilgal), on which the new hospital has been built, extends to about ten acres. It is situated on the slopes of Kinnoull Hill about 200 feet above sea-level, and is about one mile from Perth, on the east side of the river. The private rooms, verandas, and garden face south and west, and it commands to the north a magnificent view of the valley of the Tay and the mountains beyond. The hospital consists of two wards and a central admission block, the latter containing on the ground floor a medical office, reception room, surgery and dental room, electrical treatment room, dispensary, and laboratory, all connecting with the main entrance hall. The electrical treatment room is fitted with an ultra-violet projector, radiant heat lamps, and apparatus for faradic, galvanic, and Schnee baths.

Cooking is done by gas, oil fuel being used for both the central heating and the supply of domestic hot water. Rooms are heated by a panel system which dispenses with cumbrous radiators, prevents convection air currents and dust, and ensures an adequate supply of radiant heat. Each ward unit comprises a dormitory with eight to eleven beds, a day-room or lounge and dining-room, six private bedrooms, three observation private bedrooms, two bathrooms, a clinical treatment room, and a veranda. The south side of each dormitory consists of three sheets of glass with controlled opening. Floors throughout are of oak, the doors and other fittings are of Lagos mahogany, and all metal parts are chromium-plated. The cost of the hospital, including the laying out of new roads, grounds, etc., is approximately £21,500.

Selkirk Hospital

The annual meeting of the Selkirk Cottage Hospital Association, which manages Viewfield Nursing Home, was held on June 4th under the presidency of Provost Ballantyne, who intimated that the endowment fund of the hospital has been increased by £900 during the past year, and now amounted to over £9,300. The committee recommended that subscribers to the hospital should be charged at the rate of £3 per week in maternity cases, and that for private rooms they should pay £1 less than non-subscribers. In the course of the year, 197 patients were treated under this scheme of payments, including 157 from the burgh of Selkirk and 40 from the county.

Dundee Royal Infirmary

The annual meeting of Dundee Royal Infirmary was held on June 8th. Mr. Athole F. Stewart, who presided, said that he did not think the majority of people realized the acute nature of the financial problem with which the directors of the hospital were faced. On its present basis the cost of running the institution for a week amounted to approximately £1,000, while the revenue for the corresponding period was about £600. There had been a deficiency of practically £23,000 in the past year. This meant that if the expenditure were to be kept below the income, 4,500 people who needed attention within the infirmary would have to be turned away annually. The reserve fund was now practically exhausted, and the directors appealed to the citizens of Dundee and to the inhabitants of the neighbouring counties to evolve some scheme which would ensure that the efficiency and usefulness of the Royal Infirmary would not be impaired for lack of funds. It was agreed that a sum of £24,583 should be withdrawn from the reserve fund and applied to the extinction of the deficit on the accounts of the infirmary and convalescent home. It was also agreed that a sum of £10,000 should be expended for the provision of a new pathological department and mortuary.

Dr. William Muir

The sum of £581, collected during his illness by the patients of the late Dr. William Muir, who died in March, has been presented to his family as a testimony to the work he had done in the Davidson's Mains district (near Edinburgh) for over thirty-five years. Dr. Muir graduated M.B. at Glasgow in 1888, and, in spite of a busy practice, took a keen interest in public affairs, being chairman for some time of the local school board.

Ireland

Health Services in Northern Ireland

In the Northern House of Commons Professor R. J. Johnstone, M.D. (Queen's University), has expressed disappointment with the Home Office because he expected it would have tackled the problem of local government long ago and would have effected a great many definite improvements. Most of the patients who came to the dispensary were not paupers; they were very often respectable working people, and it was a great mistake in these days that the taint of the Poor Law should hang over that important medical service. He hoped that the Government would use the farm at Richhill as an epileptic colony. At the present time epileptics, unless their relatives or friends could look after them at home, were segregated in a workhouse. If a colony were established they could be placed out in the open air, and the workhouses would be relieved of an unnecessary population.

Drumcondra Hospital, Dublin

The annual meeting of the Drumcondra Hospital was held recently under the presidency of the Lord Mayor of Dublin. According to the report for 1930 the work of the hospital was well maintained, and further improvement had been effected in the financial position. The outstanding event of the year was the institution of the new outdoor annexe—the Santry Shelter—for the accommodation of patients whose complaints responded to open-air treatment. In appealing for further financial support the committee considers that in view of the rapid development of the neighbourhood, the work of the hospital is bound to become heavier. It states that the Drumcondra Hospital did not participate in the sweepstakes scheme, but relied, as in the past, on the material help of those who realized that the relief of suffering was a responsibility and a privilege for each individual member of the community. The report of the medical board recorded that 494 patients had been treated in the hospital wards, of whom 477 had been admitted during the year; while the extern dispensaries had been attended by over 3,000 persons. Deaths numbered 19, a mortality of 3.8 per cent.

Extension of Sunshine Home

In the annual report of the Sunshine Home, Stillorgan, County Dublin, it was stated that the new wing would cost £1,200, a sum which was in hand. Funds were urgently needed, however, for the maintenance of the new beds. During the year 1930-31 the number of cases dealt with and the number of children discharged cured was larger than in the previous year, and as the large number of

cases awaiting admission continued to grow, the committee had decided to extend the institution. Dr. Angela Russell said that the Home prevented and cured the diseases of infancy. Every child in the Home had a chance to become a healthy and useful citizen. The Sunshine Home helped to undo the harm which the slums had done. The report was adopted unanimously.

County Sligo Mental Hospital

In the annual report on the Sligo and Leitrim Mental Hospital, Dr. J. Dunne, resident medical superintendent, states that the treatment in the majority of instances, where definite causes cannot be assigned, is symptomatic. There were only a few types of mental disease to which a definite form could be assigned—for example, general paralysis of the insane, encephalitis lethargica, and confusional insanity. The hospital was lacking in two respects—namely, it was seriously overcrowded, and, instead of wards being bright, cheerful, and well ventilated, they were dark and stuffy, which was necessarily depressing, and was bound to defer seriously the chances of recovery.

India

Stillbirth and Neo-natal Death

With the aid, and under the auspices, of the Lady Irwin Research Fund, Dr. Christine J. Thomson has completed a preliminary inquiry into stillbirth and neo-natal death in India. Her report has now been published by Messrs. H. K. Lewis and Co., Ltd., price 1s. 6d. net. The work began in 1929 at the Haffkine Institute, Bombay, as part of a wider inquiry into maternal and infantile mortality being conducted by Margaret I. Balfour and her colleagues under the Indian Research Fund Association. It was subsequently continued in Madras, where a larger amount of post-mortem material was available. The inquiry was originally planned to last for one year, and it was hoped to base the pathological findings on the examination of at least 300 cases, but, owing to various religious customs interfering with necropsies, the series comprised only 200 cases. It was then decided to issue an all-India questionary, with a view to obtaining information from the obstetrical registers of the various women's hospitals or special wards regarding the main factors leading to stillbirth and neo-natal death throughout the country. These data, relating to more than 3,700 cases, were classified according to the approximate primary causes of death, and served as a useful check upon the findings of the post-mortem series.

In her report Dr. Thomson deals with the special conditions in India which lower the resistance to disease, and particularly the purdah system; the widespread employment of untrained native midwives; the conservatism in obtaining hospital treatment, even for complicated cases; and the administrative difficulties of providing adequate medical aid for a large rural population. A special effort was made to estimate the occurrence of syphilis as a factor in stillbirth and neo-natal disease; it appeared to play a much smaller part as a primary cause than has been imagined hitherto. Each necropsy included a comprehensive search for this infection, while several series of blood tests were performed in Bombay, Calcutta, and Madras, with the co-operation of various Government laboratories; the positive results ranged from 12.5 to 13.6 per cent. In the post-mortem series the incidence of undoubted syphilis was 14.5 per cent., while a further 4 per cent. were classified as "probable," or "possible," cases of this disease. The actual deaths primarily due to syphilis amounted to 16.5 per cent. No fewer than 83.7 per cent. of the syphilitic foetuses were macerated, but of the total macerated foetuses in the whole series only 36.4 per cent. were syphilitic, a figure in close accordance with findings in Western countries. The complications of labour accounted for a larger percentage of stillbirths and neo-natal deaths in the majority of cities or districts of India investigated than in Great Britain, though for Bombay, Calcutta, and Madras the figures were approximately the same. Ante-partum haemorrhage showed a somewhat lower figure than in the West, but the foetal or neo-natal mortality was relatively high. There was a marked variation in the geographical distribution of eclampsia, and its severity appeared to vary considerably in different localities, the maternal mortality in Calcutta—owing to various factors—being extremely high. A much higher proportion of the deaths was attributable to "acute maternal disease" than is the case in the West. The incidence of malaria was low, but this would necessarily be higher in epidemic regions. The "anaemias of pregnancy," while a potent factor in maternal mortality, did not play a large part in the causation of foetal or neo-natal death as a whole. Margaret Balfour assessed 35.6 of the maternal deaths in India as a whole as due to this cause, but in the present series it was incriminated in only 2 per cent. of the foetal deaths. Dr. Thomson considers that this figure is probably an underestimate of the true occurrence of the disease, but believes that it was undoubtedly much less concerned with the foetal and neo-natal deaths than were labour complications. There was, however, an exceptionally high mortality from this cause in certain parts of India—for example, in Shikarpur in Sind. Congenital malformations were not more common in India than elsewhere, but higher percentages of malformations, and diseases of the urinary system, were found than hitherto reported in Great Britain. The incidence of placental disease was similar to that in the West, and leucocytosis was present in more than 10 per cent. of placentas examined. Prematurity is essentially an important factor in neo-natal death in the East, though no scientific data are yet available regarding its actual occurrence as a primary cause of stillbirth and neo-natal death.

Cholera Outbreak in Bombay

In 1928 Bombay experienced an unusually high death rate, and the figure rose further in 1929 owing to a heavy increase of epidemic diseases in the presidency, with a serious incidence of cholera and malaria in Sind. From 1918 to 1922 there was a steady improvement as regards the total mortality figures, but this was followed by a rise, 1929 being the worst year in this respect during the last decade. The cholera epidemic in 1929, as in previous years, entered Sind from the Punjab, and was spread along the canals and by human infection. The people in several areas became panic-stricken and scattered in all directions, thus contributing to the wide extension of the disease throughout the province. Energetic preventive measures were adopted, and most of the local authorities arranged for the sterilization of all drinking water, and the maintenance of stocks of potassium permanganate powder and pills. A large number of inoculations were performed, and educational activities were intensified. There is reason to believe that in 1930 the cholera incidence was much less. The control of the various religious fairs during 1929 was good, and in many cases there were no outbreaks of disease of any kind. The wells were treated systematically with permanganate solution; river beds were guarded day and night, in order to avoid contamination of the water used by the pilgrims for drinking and bathing; chlorinated water was provided and used; and the segregation was successfully arranged of infected persons and their contacts attending these fairs.

Forecasting Epidemics

Sir Leonard Rogers has for many years been endeavouring to trace a connexion between the incidence of cholera, small-pox, and plague and meteorological conditions. In the *Indian Medical Gazette* of April, 1930, he gave a forecast of the probable incidence of these conditions during that year, and in the issue of the *Gazette* for last Feburary he shows how the event proved him to be substantially correct, especially as regards cholera and plague. He submits also in this later issue a forecast of the probable variations of these three diseases in India during 1931, based on the meteorological observations of the previous year. Once again in 1930 the south-west monsoon rains were very regularly distributed and approximately normal in amount over the greater part of India, thus rendering the incidence of epidemic disease rather difficult to foretell. Sir Leonard Rogers believed that no very serious epidemic of cholera was likely to occur during 1931, or, in the case of Assam, Bengal, and South-East Madras, during the usual cholera season of those areas from November, 1930, onwards. No very severe small-pox epidemic is probable anywhere during the current year, though the incidence of this disease is likely to be above the average of 1930 in the Punjab and North-West Frontier Provinces. In the Central Provinces there will probably be fewer outbreaks than in 1930. A low plague incidence is expected in Bihar and Orissa, the United Provinces, and the South Deccan ; about the average figure for the Central Provinces and North Deccan ; and some slight excess over the recent prevalence in the Punjab. Sir Leonard Rogers received in London the information on which his conclusions are based in the form of data supplied by the Director-General of *Observations in India*.

Correspondence

THE HARVEY TOWER

SIR,—We have to-day completed a delightful three-day celebration of the centenary of the Harveian Society of London. The celebration has been most admirably arranged, and reflects great credit on the society's officers. The address by Dr. Raymond Crawfurd at St. Bartholomew's Hospital, the dinner at the Grocers' Hall, the address by the Bishop of Colchester at Hempstead Church, and the reception by Lady Lloyd were all excellent. The doyen of the American physicians, the venerable but ever-youthful Dr. Welch, attended all these celebrations, coming, like Catullus to his brother's tomb, *multas per gentes et multa per aequora vectus*. Replying for the guests at the dinner, he said he found it hard for an American in the beautiful surroundings of the Grocers' Hall to express his feelings adequately ; that he found that the British surpassed all other nations in conducting these festivals : "*You do these things well.*" To-day, Sir, he visited Hempstead Church and the Harvey tomb and monument, inspected the brasses, including those to the memory of the Huntingtons (1498), the ancestors of the American family of that name, inspected the fallen bells, and viewed the rubble heaps in the churchyard—the remains of the Harvey Tower. When I think of the way Americans treat *their* heroes, of the home of Washington and the memorial to Lincoln, I cannot help feeling that the Americans would not have left the ruined tower of Harvey's church unbuilt for half a century.

Next year will be celebrated another centenary—that of the British Medical Association—under the presidency of Lord Dawson, the President of the Royal College of Physicians. The distinguished foreigners who will attend it will wish to visit Harvey's church at Hempstead. The committee of the Harvey Church Tower Memorial Fund has collected about £2,500 ; the Harveian Society of London has collected about £200 for reconditioning the bells. These are about half the sums required. If each member of the Association who has not already subscribed to the Harvey Memorial Fund will send 5s. to the honorary secretary, Dr. Arnold Stott (58, Harley Street, W.1), the tower will be rebuilt and the bells rehung by the date of the Association's centenary. Is it too much to ask?—I am, etc.,

London, W., June 13th. HERBERT R. SPENCER.

INTERNATIONAL LEAGUE AGAINST RHEUMATISM

SIR,—Will you allow me to call the attention of your readers to a matter connected with the International League against Rheumatism, which I think is deserving of their serious consideration? This league was founded some six years ago in order to bring together the many scattered workers (groups and individuals) who were seeking to grapple with rheumatic diseases in different countries ; to arouse interest in the large and vital medical and economic problems which these diseases present ; and by mutual international studies and discussions to clarify the confusion and uncertainties existing in nomenclature, etiology, diagnosis, and treatment.

The chief activities of the league have been: the formation of a number of national committees in Europe and America, many of these now flourishing and valuable medico-industrial organizations ; the establishment of a central information bureau and library in Amsterdam, with a card index of literature on rheumatic diseases ; the holding of periodical international congresses ; and the production of an international organ (the *Acta Rheumatologica*), of which the ninth number has just been published. Keen and fruitful discussions have already taken place at Amsterdam, Budapest, and last year at Liége and Brussels, the next being arranged for Rome in 1932.

It is obvious that such a league, inspiring and co-ordinating the work of other bodies, cannot be conducted without a reasonable expenditure. Owing to the amount of ungrudging voluntary service given, especially by its honorary secretary Dr. van Breemen, these expenses are very low compared with the bulk of work achieved. The small income is derived from contributions from Government funds, national committees, public bodies, and private friends, also from the sale of the journal. The audited statement of accounts for last year shows a considerable deficit, and I understand that the chairman of the Finance Committee, Professor Prusik of Prague, is making some appeal to various Continental committees, and some time ago also approached the British Red Cross Society in England.

I write to ask whether the medical profession in this country will not make some personal contribution to this important work. In England we have benefited in recent years not a little from the work of the league, having owed to it, in the first instance, an awakened public interest and the actual materialization of a "Campaign against Rheumatism." And yet, apart from three or four individual donations, nothing has been sent from our country towards the expenses of the league. As an Englishman (and incidentally as president of the league) I cannot but feel this position to be unworthy. Committees and individuals from far poorer countries than our own give regular annual grants, and one would like to see a fund of at least £200 a year subscribed from our own country. There is no nation in the world so deeply concerned in the solution of the problem of the suffering and economic loss brought about by the rheumatic diseases as Great Britain, and I hope that

some of my medical colleagues will come forward and give a generous lead in this matter.

Cheques can be sent to the honorary treasurers of the Ligue Internationale contre le Rhumatisme, at their bank, Ontvang-en Betaalkas, Doelenstraat, Amsterdam, or to me. Full information is always obtainable from the central office, Keizersgracht 489, Amsterdam.—I am, etc.,

R. FORTESCUE FOX.

36, Devonshire Place, W.1, June 8th.

PSEUDO-ARGYLL ROBERTSON PUPILS WITH ABSENT TENDON REFLEXES

SIR,—The avowed object of my paper under this title was to make it known that pupils conforming to the prevailing loose definition of the Argyll Robertson sign may be associated with absence of the tendon jerks in patients free from syphilis; and that the distinction from syphilis may be made with certainty by observing the behaviour of the pupils during the act of accommodation.

The wording of Dr. Parkes Weber's letter in your issue of June 6th (p. 1001) might be taken to mean that this twofold message was not a new contribution to our knowledge. He writes that "no allusion is made to the first account of such cases published in England—namely, that by Dr. C. Markus." This author did not give "an account of such cases"; he described an isolated case in a paper on "A peculiar pupil phenomenon in cases of partial iridoplegia." In this case, with a myotonic pupil and absent knee- and ankle-jerks, and in almost all the others that have been described—I have found about a dozen isolated examples in ophthalmological journals—a diagnosis of syphilis of the nervous system was either made outright or seriously entertained. It is interesting to recall that Dr. Markus, while admitting that the signs in his case were suggestive of congenital syphilis, was "inclined to take a less serious view." To-day we do not incline to a certain view when confronted with these signs; we know that they have no relation to syphilis.

Dr. Parkes Weber asks if I mean to separate cases with myotonic pupils alone from those with myotonic pupils and absent tendon jerks. I said in my paper that it was *more than probable that some of the cases* with abnormal pupils only were examples of a milder form of the same disorder as that in which the tendon jerks were also abnormal. I would now amplify this by substituting the words *certain that most of the cases,* for those in italics above.

A study of the published cases has caused me to form the opinion that the group with myotonic pupils alone is almost, but not quite, homogeneous etiologically; the group I have described with myotonic pupils and absent tendon jerks is certainly homogeneous, and constitutes a harmless disorder *sui generis* of unknown origin.—I am, etc.,

London, W., June 6th. W. J. ADIE.

EUROPEAN WOMEN AND CHILDREN IN THE TROPICS

SIR,—In the *Journal* of February 14th you report an interesting discussion on the above subject which took place at a meeting of the Royal Society of Medicine. The subject is of great interest to us out in the East, and one on which an interchange of views is always helpful.

I myself have practised nine years in the Tropics, but my professional experience has been limited to the lowlands of Siam. Here, however, we have a climate which is a severe test to all, and conditions of life which are difficult to many. The temperature rarely exceeds 100° in the shade, but it is a damp heat, and continues throughout the year, the cool season, so called, being often of very short duration and never really cold. Life is monotonous, as geographically we are in a backwater, and we feel rather "out of the world" as compared with big shipping centres, like Singapore and Hong-Kong. Home conditions are as good as one can expect, owing to excellent electric light and fan service, good water supply, good cold storage, and fairly good housing accommodation—all, also, at a very good expensive price. But a house in the East is never the same as an English home, and Chinese servants, excellent for undiscriminating bachelors, can drive a conscientious housewife to the verge of a nervous breakdown.

Adaptability, an equable temperament, moderation, and a determination to get the best out of life, are four great assets for life in the East, and unfortunately few women possess them all. Life is admittedly more difficult for them, as they have not sufficient to do or think about; and so the small things of life—the bites of mosquitos, the plague of flying animals of every description that come with the rain, the feeling of discomfort in wet clothes, the petty thefts of the cook, the effort of explaining to servants who understand little English and whose language is not easy to master—all these things thrust themselves on the conscious mind, out of all proportion to their importance. Many seek relief from domestic troubles by virtually giving up home life; they try to avoid monotony by over-indulgence in games, bridge, dinner parties, with their train of late nights, excitement, and excessive alcohol. These women are hardly ever in their homes, and seem to have an obsession to be always out and about doing things, trying to forget, and trying to make the time pass till the next leave comes, or nervous exhaustion drives them home. Others may go to the other extreme, give up their games, shun all social engagements and responsibilities, and become "housebound." These, if they have not the absorbing interest of a hobby, or an outlet for their emotions in the care of a baby, soon get depressed and neurasthenic.

The woman who does best here is the woman who takes a real interest in her house and garden, her baby—and she should have one, if she can—and last, but not least, her husband. She should be able to combine these interests with a modicum of healthy exercise and entertaining, and she should, above all, be able to preserve her sense of humour and of the relative proportion of things that matter. She will find a working knowledge of the language of the country a great help, and, if she can develop an interest in a hobby, or some social work, such as the organization of the local library or musical society, etc., she will find the time pass more happily.

Babies are a godsend to many a woman in the East, and should be encouraged. They do very well up to about 2 years, keep fairly well up to 6 years, but should go home not later than that age. Mentally they develop rapidly, but they become nervous, anaemic, and debilitated if kept out longer. European nurses are a gamble; they may be excellent, but in a small station, where there may be few of their own class, they are apt to get lonely and discontented; and in a house staffed entirely by Eastern servants they occupy a difficult position in the home. Many Chinese amahs are excellent. They should be carefully examined medically, of course, and, like all Eastern servants, require constant supervision.

I must express surprise at Dr. Aldo Castellani's statement that very few European women in the Tropics could nurse their babies for more than a few weeks. On analysis of my cases I find that approximately 90 per cent. have fed their babies for five months, and a number have done it longer. Natural feeding is still the best form of nourishment, particularly in the Tropics, where fresh, clean cow's milk is almost unobtainable, and

it can be done ; only the mother has to concentrate on it. She has to settle down to a placid existence for the few extra months, she has to go to bed early, give up her games, and take extra nourishment. It is hard, after the weary months of pregnancy, and it is not conducive to a quick return to the prematernity figure, but most mothers realize that it is worth it.

I must apologize for bringing up this discussion some months after it has appeared in your columns, but that is partly because of the necessary delay in the post.—I am, etc.,

Bangkok, Siam, April 15th. H. W. TOMS.

OPERATION FOR CATARACT

SIR,—The letter by Dr. H. M. Traquair, in your issue of June 6th, is important from a practical point of view. There is no doubt that his experience of dissatisfied patients after operation for removal of monocular cataract is that of most ophthalmic surgeons. Further, I agree that where the operation is done at all, one is usually persuaded to do it by the patient, even though the uncomfortable post-operative condition has been carefully explained beforehand. The two chief arguments in favour of removal of monocular cataract are, where the other eye possesses good vision, improvement in the visual field, and improvement in the appearance of the pupil. While the former is certainly an advantage in these days of fast-moving traffic, the latter appeals particularly to the female sex, where the milky appearance of the pupil is a source of inquiry and annoyance to the patient. I have found this type of patient much more appreciative than any other, after operation, especially where an iridectomy has not been done at all, or, if done, is of the small peripheral type. Dr. Traquair's experience that patients can shoot pheasants after operation as well as before the development of cataract is as it should be. The resulting improvement in the visual field after operation is all-important in game shooting. The act of game shooting is a beautifully co-ordinated movement of the whole body, and, even when the vision is only fair, can be carried out satisfactorily provided that the correct movements of stance, swing, and anticipation are employed. Most first-class game shots shoot with both eyes open, in contrast with rifle shooting. Again, the loss of accommodation after the removal of the lens is no handicap to game shooting.—I am, etc.,

Blackpool, June 13th. W. BARRIE BROWNLIE.

TREATMENT OF DYSMENORRHOEA

SIR,—I have read with much interest Mr. Venn Dunn's paper on the treatment of dysmenorrhoea in your issue of June 6th, and it is a most remarkable fact that, in a communication professing to give advice on the most effective methods of alleviating, and, if possible, curing this most painful concomitant of a normal process, no mention is made of the benefits of diathermy applied from front to back through the pelvis.

It is so frequently young unmarried girls who are the sufferers from dysmenorrhoea. Such patients may be questioned and examined per rectum, but a routine per vaginam examination is out of the question in general practice, and more often than not the result of such examination as can be made is negative. What is to be done?

We may classify such patients into the psychological or endocrine type. But are we much further on? It is not every medical man who has the time or the personality to practise psychotherapy—the successful administration of which is only given to a small proportion of busy practitioners ; and, as means of treatment, it is little more certain than endocrine therapy, which, at present, is in a state of nebulous chaos.

More than thirty years ago Dr. Betton Massey of Philadelphia advocated treating dysmenorrhoea by through-and-through galvanism—this was long before diathermy was discovered—and I have used this older method with success. Anyone *au courant* with modern therapeutics as practised on the Continent and in America would certainly give diathermy pride of place in the treatment of dysmenorrhoea of doubtful origin. When this remedy fails, then, and not till then, is it necessary to submit virgins to vaginal examination. In the case of those who are not virgins the position is different ; but even here, when no definite cause can be found, diathermy will usually effect a cure ; and, where diathermy is not available, galvanism is a very good second.

It is common knowledge that the action of diathermy is to cause a dilatation of the blood vessels, and so it increases the blood supply and also, in a less understood manner, it regulates neuro-muscular function. Are not these two qualities exactly what is wanted in the treatment of simple dysmenorrhoea ; and, if treatment is to be administered, is not success more likely to be obtained by these methods than by a reliance on analgesics and the advertised claims of makers of so-called endocrine preparations, or by submitting the patient to dilatation " which may have to be repeated in three months' time " or other surgical procedure which may or may not be successful?

The lamentable want of knowledge of the field of usefulness of electrotherapy is daily brought home to those of us who practise this most useful specialty, and one is forced to conclude that the lack of appreciation of its efficacy in certain conditions must be traditional in this country.—I am, etc.,

Cheltenham, June 9th. J. CURTIS WEBB.

KERATODERMIA BLENNORRHAGICA

SIR,—The above diagnosis in the case described under this title in the *British Medical Journal* of June 6th (p. 979) does not appear to have been established, either on clinical or bacteriological grounds, and would seem to be unwarranted, as there was no history of gonorrhoea nor was any evidence of this disease discovered. The diagnosis was apparently made because a keratotic eruption cleared up after treatment, among other remedies, by a gonococcal vaccine.

Barrett (*Arch. Derm. and Syph.*, 1930, xxii, 627) has stated that in order to establish a diagnosis of keratodermia blennorrhagica three things are essential—namely, (1) a gonorrhoeal infection of the uro-genital tract ; (2) a keratotic eruption ; and (3) a gonorrhoeal arthritis. Of eight cases recently published six conformed to these requirements (as did two cases which I have had the opportunity of observing), while of the other two, one described by Louste and Lévy Franckel (*Bull. Soc. Franç. de Derm. et de Syph.*, 1930, xxxvii, 378) was a rare case in a child, 5 years of age, with gonorrhoeal vulvitis but no arthritis, and the other had a history suggestive of recent gonorrhoeal epididymitis but no active lesions ; this case, however, was complicated, as the patient also had a syphilitic infection.

Adamson (*Brit. Journ. Derm. and Syph.*, 1920, xxxii, 183) has pointed out that there is a striking similarity sometimes between arthropathic psoriasis and keratodermia blennorrhagica.

In view of the findings in this case it would seem more probable that the condition was associated with the abundant streptococcal infection proved to be present, rather than with a hypothetical infection with the gonococcus which could not be demonstrated.—I am, etc.,

Clifton, Bristol, June 9th. NORMAN BURGESS, M.A., M.D.Camb., M.R.C.P.

GONOCOCCAL RHINITIS

SIR,—It is very gratifying to note the interest evoked by the article by Dr. Kirkland and myself on gonococcal rhinitis in an infant, published in the *Journal* of February 14th. The case was reported, not for scientific record, but to provoke discussion on a very important but much neglected subject. Admittedly the diagnosis was not complete, because no culture was made and the gonococcal complement-fixation reaction of the baby's serum was not determined. Nevertheless, my thesis is that typical gonococci cannot be mistaken by one experienced in recognizing these organisms.

I agree with Dr. A. Scott, who points out in the *Journal* of March 28th that it is very difficult to culture the gonococcus in the presence of other hardier organisms. I should like to hear from Dr. Assinder his method of culturing the gonococcus in mixed infections, and how he identifies them by fermentation tests in the possible presence of *Micrococcus catarrhalis*. Quite often have I been able to identify the gonococcus in a smear of prostatic fluid stained by methylene blue, yet have not been able to identify them in culture owing to the medium being overgrown by staphylococci and diphtheroids. Media rich in trephones, such as Hirschfeld's testicular and Pelouse's calf-brain agar, have all been tried, but without much success. I contend that in a case of mixed infection the identification of an organism from the nose by fermentation tests (as suggested by Dr. Assinder in the *Journal* of February 28th) is not practicable. I should be glad to know of any medium which would inhibit the growth of other organisms and yet promote the growth of the gonococcus. I suggest that such a medium is urgently required, and research devoted to its isolation should be encouraged in every way possible.

The complement-fixation reaction of the baby's serum should have been determined, but it is probable that, as is the case in other early acute gonococcal infections, it would have been negative.

Dr. Orpwood Price raises a very important controversial point. In the absence of positive blood reaction and the isolation of the gonococcus by culture, is it justifiable to regard a chronic non-symptomatic prostatitis in the male adult as gonococcal infection merely because the prostatic fluid contains pus? Where there's smoke there's fire! I maintain, therefore, that where there is a history of antecedent gonorrhoea it is safer to treat the patient as suffering from an uncured gonococcal focus than to assure him that he has "nothing to worry about" as is so commonly done, with tragic sequelae. The "certain" diagnosis of chronic latent gonorrhoea presents very great difficulties, especially in married persons where the symptoms are slight or even absent. "Gonococcosis d'emblée" is, in my opinion, far commoner than suspected.

In conclusion, I suggest that when there is naked-eye or microscopical evidence of gonococcal infection, medical men should be extremely cautious of pronouncing a patient cured merely because the cultural and serological results are negative. Recently, at the instigation of the author, a Laboratory of Neisserian Research has been established in Sydney, the main object of which is to secure a higher standard of cure in gonorrhoea than has been demanded by the medical profession in the past. In view of the extreme prevalence of latent gonorrhoea (10 per cent. of the adult population) it is lamentable to observe the apathy of the medical profession towards this tremendously important problem. Especially is this so in Australia. Here there are no lectureships in venereology at any of the universities; there are no opportunities for post-graduate work in the modern diagnosis and treatment of gonorrhoea and syphilis; and there is no section of the British Medical Association for the study of venereal diseases.—I am, etc.,

Sydney, New South Wales, May 7th. ROBERT V. STORER.

FRACTURE OF THE NECK OF THE FEMUR

SIR,—In recent numbers of the *Journal* attention has been drawn to the important question of fractures of the neck of the femur. As regards treatment, I must confess that I have never had any success with the Whitman type of plaster-of-Paris spica, nor can I fully concur in its underlying principles. To my mind the essentials in treatment are extension with abduction; then, correction of the excessive external rotation of the foot. These can surely be best obtained by skeletal traction in such a splint as the Thomas knee splint. With faithful attention to detail there is absolutely no reason why full and adequate reduction should not be secured; and if it is maintained and the patient is transferred to a walking calliper splint after some weeks, a good result will be obtained, but not under three years in the case of the "intracapsular" variety. In the near future a book will be published by Constable and Co. which will contain the details of the methods I advocate. I should be only too pleased to let any reader know particulars earlier, if he so requires.—I am, etc.,

London, W., June 9th. MEURICE SINCLAIR, Major R.A.M.C. (ret.).

TREATMENT OF TABOPARESIS BY HYPERPYREXIA INDUCED BY HOT BATHS

SIR,—The article by Drs. Gibson and Gordon in the *Journal* of June 13th would appear to be worthy of special notice for the clarity of its presentation, its freedom from irrelevant matter, and more especially for directing attention to the therapeutic possibilities of hot water. It is somewhat strange that a method of treatment which demands no special apparatus beyond that contained in the average household should not be more generally resorted to. Although the induction of hyperpyrexia by hot bathing is a well-known hydrological measure, most of the literature dealing with such a procedure is contained in publications devoted to the study of the subject. References in general medical literature are comparatively few. The employment of water in its different forms and in various circumstances, both internally and externally, as a therapeutic agent, although recognized for centuries, has to some extent been regarded by the rank and file of the profession as a more or less specialized kind of treatment, and not to be naturally included in the resources of the ordinary practitioner. The reason is not far to seek.

The teaching of medical hydrology forms a very small part of the curriculum of the medical student. Prejudices die hard, and the teachers of to-day no doubt retain subconscious memories of the scant courtesy with which the "water doctors" of their day were treated. This was doubtless due to the fact that in those times practitioners of medicine ranged themselves under distinctive banners indicative of their individual school of thought and teaching. In the days when the value of a prescription was assessed by the number of its ingredients, it is not to be wondered at that the employment of water alone was not seriously considered.

Happily all this is changed, and although adequate provision for the teaching of medical hydrology is largely wanting, the profession as a whole is beginning to realize its importance. Not only are teaching facilities at present utterly inadequate, but the opportunities for research are greatly lacking. It would be ungenerous not to mention the pioneer work that has been done by Dr. Fortescue Fox in his constant efforts to obtain better facilities for the study and teaching of hydrological methods of treatment.

The study of medical hydrology is intimately bound up with the study of climatology. The two subjects go hand in hand, and while the first is neglected the second is to all intents and purposes ignored. In spite of this

a day rarely passes in the life of the ordinary practitioner when he does not have to answer some question as to the suitability of this or that locality for one or other of his patients.

I venture to suggest that the time is now ripe for the appointment of a Reader in Hydrology and Climatology at each of our medical schools. I would also suggest that the matter be taken up by the British Medical Association. It will no doubt be urged that the medical curriculum is already overloaded, and that medical students will take no interest in subjects they are not likely to be examined upon. The first objection could be met by dropping some less essential subject or part of a subject, and the second by setting an occasional question in either hydrology or climatology at the final examination. If this were done, the Reader would have no cause for complaint with regard to the paucity in the number of those attending his lectures.—I am, etc.,

London, W.1, June 15th. M. B. RAY.

MINOR SURGERY OF INFANCY

SIR,—Mr. David Levi, in his description of the operation for umbilical hernia in infants, by subcutaneous ligature, in the *Journal* of June 6th, is apparently ignorant of the practice of Mr. John Fraser, whom I saw perform this operation in 1922 in Edinburgh. That the operation has not found general favour is due to the obvious danger of including in the ligature the tail of omentum that frequently lies in these herniae, and to the fact that most of them disappear spontaneously, whether treated by strapping and halfpennies or not.

Mr. Levi, in recommending the injection of closed hydroceles of infants with sodium morrhuate to effect aseptic inflammation and cure, says: "It is not unreasonable to suppose that the inflammation might spread to the closely adjacent vas deferens and produce stenosis or stricture of it. It has therefore been my practice never to inject both hydroceles in bilateral examples of this condition." Surely to risk producing stricture of one vas deferens is a surgical error, when the simple alternative of masterly inactivity will cure the great majority of infant hydroceles. The minority would be better treated by open operation, which would not jeopardize neighbouring important structures.—I am, etc.,

London, W.1, June 8th. JAMES CROOKS.

"STREPTOCOCCI IN SCARLET FEVER": A TROPICAL VIEW-POINT

SIR,—Your review in the *Journal* dated May 30th of the sixth volume of the *Annals of the Pickett-Thomson Research Laboratory*, on "The Role of the Streptococci in Scarlet Fever," states that "the authors consider that the chief mode of spread [of scarlet fever] is by droplet infection from the respiratory tract." This, in the opinion of many, is the chief mode of infection, not only of scarlet fever, but of other diseases, such as diphtheria and rheumatic fever—except in so far as infection may take place through contaminated articles. This makes the human being the only origin and almost the only reservoir of this disease, and suggests that every new case must arise from a previous clinical case or from a carrier. It is a possible, but not an entirely, satisfactory explanation, as so much seems to depend on environmental conditions.

Something might be learned of the cause both of scarlet fever and of rheumatic fever from a study of the geographical distribution of these diseases. It may be said that neither of them occur in the Tropics. Occasional cases of scarlet fever are said to be imported into those latitudes, but the disease does not spread, and occasional cases of rheumatic fever apparently occur in the Tropics, but the cases are so rare as usually to throw doubt on the diagnosis.

Dr. William Fletcher[1] says that "in the Dutch East Indies, where scarlet fever does not occur, the bulk of the children give positive Dick reactions. With increasing age the number of negatives becomes equal to that found in countries where scarlet fever is endemic. Thus an immunity is obtained in spite of the absence of scarlet fever." This illustrates the fact that "an infection may be widespread in a population with but few, if any, cases of the disease showing themselves." There is something in the Tropics which leads to a Dick-negative reaction in the population, but something also is present, or may be absent, which prevents scarlet fever from showing itself in its normal form, and this leads to the supposition that there are two factors necessary for the production of the disease.

Dr. Coburn[2] writes that the number of haemolytic streptococci found in the throats of rheumatic fever cases in New York diminishes very greatly when these cases are removed to Porto Rico, which is 5 degrees inside the Tropics; that is to say, we have the contradictory position that the streptococci of the one disease, rheumatic fever, tends to disappear in the Tropics, whereas the, apparently, similar organism of scarlet fever must, on the evidence of the Dick test, be endemic in the (tropical) Dutch East Indies, where scarlet fever does not occur. Neither of these diseases is found in the Tropics except very, very occasionally.

Coburn suggests that in New York there is an environmental condition favourable to the growth of the streptococcus of rheumatic fever which is absent or almost so in Porto Rico. This apparently should also apply to the streptococcus of scarlet fever; there can hardly be a climate condition which prevents a bacillus of rheumatic fever from thriving in the throat in the Tropics, though it can thrive in the same throat in New York. It would seem, rather, that in the absence of frequent reinfections the patient can clear himself of an organism, as in Porto Rico, but that when an environment such as there is in New York keeps up a more constant supply, the organism cannot be thrown off.

Seeing that in the big "public" schools, where throat infections account for about 80 per cent. of the total invalidity, there is hardly any rheumatic fever, and that Dr. Stalybrass says that school infection is not of importance in scarlet fever, it seems probable that the environmental condition in question is one of bad sanitation rather than of the propinquity of infected throats. Dr. Coburn suggests that the bacterial agent is not the only factor responsible for the rheumatic state. The same may apply to scarlet fever. In some ways scarlet fever and rheumatic fever behave similarly with regard to the Tropics, and it appears that if there are two factors responsible for the rheumatic state the same may be true of scarlet fever.—I am, etc.,

J. TERTIUS CLARKE,
Late Medical Officer and Health Officer, Perak, F.M.S.

Harrow, June 8th.

PREVENTION OF RENAL COMPLICATIONS IN SCARLET FEVER

SIR,—In reference to Dr. Samson's letter in your issue of June 6th, we have devised a method for prevention of renal complications after scarlet fever in the last 600 cases admitted to this hospital, which is giving even better results. We administer alkalis (sodii bicarb., 25 grains, pot. bicarb., 5 grains, four-hourly) until the urine is alkaline to litmus. This takes three to four days. This brief administration of alkalis has no effect on the renal complication rate, but it reduces the alkali reserve to normal, and thereafter no test we have applied shows that there is any reduced reserve throughout the attack.

[1] *British Medical Journal*, 1928, i, 448.
[2] *The Factor of Infection in the Rheumatic State.*

The success of Dr. Samson's method is evidently not due to abolition of "acidosis." It has been shown that dogs which have received a lethal dose of $HgCl_2$ can be saved from death by administering to them large doses of salts. This is apparently due to the excess of salt turning out the + -charged Hg ion from its combination with the body proteins. I have suggested elsewhere[1] that true toxins behave like polyvalent + -charged metallic ions causing colloid flocculation in the blood and tissues, and that a good part of the pathology of the toxins is possibly explicable on that theory. The success of Dr. Samson's method is confirmatory of this.

Acting on this theory we are now giving tr. iodi mit., 20 minims in milk four-hourly, and thyroid, 4 grains, once per day for a fortnight after admission (in addition to the short alkaline treatment), as suggested by McDonagh's work. Gortner has shown that iodine as KI is the most potent agent in peptizing the colloids of wheat flour—a very suggestive experiment in this connexion. In our last 600 cases of scarlet fever, four cases have had a trace of albumin for four days only, and three had nephritis in the fourth week, which all cleared up completely in three weeks on repeating the thyroid and iodine until the urine was clear of albumin, and alkalis until the urine was alkaline again. This gives a percentage of just over 1 (one-third of Dr. Samson's rate with alkalis only), compared with a control group of 1,080 cases which showed a percentage of 10.7 with renal complications (a figure almost identical with Dr. Samson's control group of 11 per cent.).

It would be interesting to try this method on a case of acute nephritis, as the three cases treated in this way cleared up in half the usual time, which is usually about six weeks in scarlatinal nephritis.—I am, etc.,

Haim Green Hospital and Sanatorium, Pill, near Bristol, June 8th. B. A. PETERS, M.D.

AVERTIN ANAESTHESIA

SIR,—The report of the meeting of the Pharmacological Section of the Royal Society of Medicine in your issue of June 13th gives a rather misleading impression of what I said. My remarks were not confined to the mention of a successful administration of avertin for the performance of cholecystectomy in a case of congenital cystic liver. I stated that I had given this drug in 435 cases, many of the patients being young children and old people, and twelve of the operations being for removal of the gall-bladder. In no instance had ill effects been observed, and I was satisfied that in avertin the anaesthetist has a drug of immense value. I was not convinced by the experimental evidence brought forward by Dr. Parsons as the result of an investigation on five rabbits. Dr. Parsons himself, as your report states, admitted that the evidence was inconclusive, and as he proposes to repeat the experiments upon dogs his attention might be directed to the recent work of Bolliger and Maddox (*Current Researches in Anaesthesia and Analgesia*, 1931, x), which confirms the work of Wesley Bourne, Bruger, and Dreyer. Bolliger and Maddox state that "normal dogs, after repeated and potent doses of avertin, yielded no evidence of recent acute hepatic damage, as is easily obtained by chloroform anaesthesia."

It is difficult to agree with Sir William Willcox that avertin should be used with great caution. Provided it is given in accordance with the principles and instructions which have been clearly laid down, it can be used with complete safety. His remark that it is not a substance which should be let loose on the medical profession would apply with more justification to chloroform.—I am, etc.,

London, N.W.1, June 15th. FRANCIS E. SHIPWAY.

[1] *Medical Officer*, January 24th, 1931.

CONVULSIONS DURING GENERAL ANAESTHESIA

SIR,—Whatever may be the cause of convulsions during surgical anaesthesia it is not, as your correspondent suggests, "lightness of anaesthesia." If he will investigate the reported instances of ether convulsions he will find that in almost every one it is either expressly stated that the patient was deeply under, or else it is plain that this was so from the context. In fact, if one were asked to select one common factor in attempting to define the causation of this very puzzling phenomenon, one would, I think, state that deep narcosis was the condition most often present.—I am, etc.,

London, W.1, June 11th. J. BLOMFIELD.

SIR,—I agree with Dr. W. S. Laurie (June 6th, p. 1002) that it is certainly possible for an attack of epileptic spasms to appear during anaesthesia. I have twice witnessed their onset, though they passed off during the surgical stage and were only faintly observable during recovery. Apart from the event of slight clonic movements in the presence of slight degrees of anoxaemia, there is also a very common appearance of clonic muscular movements at the moment of the application of dental forceps in children under the influence of gas and oxygen, so that reflex effects must be ruled out in making a diagnosis of true epilepsy.—I am, etc.,

London, N.W.1, June 10th. BELLAMY GARDNER.

AFRICAN TICK FEVER

SIR,—I have just received vol. viii of the *System of Bacteriology*, which is in process of being issued by the Medical Research Council, and would like to congratulate the editors and everyone concerned on the excellence of the work. Nevertheless, in an authoritative work of this kind it is desirable that the facts stated should be accurate, and that as far as possible justice should be done to the various observers who have worked at any given disease. One is reminded of the controversy which took place about twenty-seven years ago as to the relative parts played by Castellani, Bruce, and myself in the elucidation of the causation and the mode of transmission of sleeping sickness. I have no desire to revive this controversy, but should like to point out that in August, 1903, when examining the blood of a suspected sleeping sickness patient, I discovered the spirochaetes of relapsing fever on several occasions in the patient's blood. I showed the films to Colonel (now Sir David) Bruce, and his comment was that they probably came from the distilled water which had been used in staining the blood film, and that they were not in the patient's blood. I pointed out to him, however, that I had stained twenty or more films from other human beings and animals that same day, and this was the only one which showed the spirochaetes. The case is fairly fully described in Part V of the reports of the Sleeping Sickness Commission, which was dated Entebbe, November 20th, 1903. This report, for some unknown reason, was withheld from publication until July, 1905, by which time Drs. Cook and Ross and Milne, all of Uganda, had rediscovered this spirochaete and obtained the credit for the discovery. In the history of African relapsing fever on page 169 of vol. viii of the *System of Bacteriology* no mention is made of my original discovery in 1903, though this fact is mentioned by Castellani and Chalmers in their *Manual of Tropical Medicine*, the first edition of which was published in 1910. As Dr. Hindle, the writer of the article in question, refers to Castellani and Chalmer's manual, I am surprised that he did not include this reference to my original observation in his historical account of African tick fever.—I am, etc.,

London, W.1, June 10th. DAVID NABARRO.

Obituary

SIR ROBERT H. FIRTH, K.B.E., C.B., F.R.C.S.

Colonel A.M.S. (Ret.)

As announced in our last issue Colonel Sir Robert Hammill Firth, K.B.E., C.B., late R.A.M.C., died in London on June 5th, aged 72. He was born in Byculla, Bombay, on December 1st, 1858, was educated at Oxford and at University College, London, and qualified as M.R.C.S. in 1879. He obtained the F.R.C.S.Eng. in 1882, and later the D.P.H. of the English Colleges in 1891.

Entering the Army as surgeon on August 4th, 1883, he attained the rank of colonel on November 13th, 1912, and retired on December 25th, 1917, when holding the post of Deputy Director of Medical Services. He served in the Tirah campaign on the North-West Frontier of India in 1897-98, receiving the medal with two clasps, and throughout the war of 1914-18, when he was twice mentioned in dispatches—in the *London Gazette* of January 1st, 1916, and on December 24th, 1917. He was assistant professor of hygiene at the Army Medical School, Netley, from 1892 to 1897, and professor of military hygiene at Netley, and later at the Royal Army College at Millbank, after the school was transferred from Netley, from 1900 to 1906. During the four years from February, 1906, to February, 1910, he was in charge of the School of Army Sanitation at Aldershot.

He collaborated with the late Colonel Notter in the production of Notter's *Theory and Practice of Hygiene*, and largely rewrote the material ten years afterwards. As he explained in his preface, "Notter and Firth" was, strictly speaking, the third edition of the book which Colonel Notter and he brought out in 1896, based upon the well-known work of Dr. Edmund A. Parkes, and the extent of the changes made in the text were such as to render the edition of 1908 practically a new work. The ninth edition appeared in 1921. Colonel Firth was also author of other books on the same subject—*Hygiene and Practical Domestic Hygiene*, and a manual of sanitation for soldiers entitled *Military Hygiene*—and in 1919 he published *Musings of an Idle Man*.

He gained the Alexander Memorial prize and medal in 1888, and again in 1891; and the Parkes Memorial prize and medal in 1889, and again in 1892. He received the C.B. in 1918, and the K.B.E. on June 2nd, 1919. He was for many years a member of council and examiner at the Royal Sanitary Institute, a member of council of the Royal Institute of Public Health, and a Fellow of the Society of Medical Officers of Health. He was also a member of the Société de Médecine Militaire Française. At the Annual Meeting of the British Medical Association at Swansea in 1903 he held office as vice-president of the Section of State Medicine. In 1884 he married Mary, daughter of William Knight of Appledore, Devon, and leaves a daughter.

Mr. ANTHONY BLACKSTOCK, F.R.C.S., orthopaedic surgeon to the Royal Hospital, Wolverhampton, and to the Guest Hospital, Dudley, who died suddenly on June 2nd, was very well known in the district in which he practised. His untimely death came as a great shock to the neighbourhood, as he had been at his usual work in the morning. Mr. Blackstock obtained the M.R.C.S., L.R.C.P. diplomas in 1917, and became M.B., B.S. in 1923, and F.R.C.S. in 1924. For some time he was surgical registrar and out-patient surgical officer to King's College Hospital. He was also a Fellow of the Royal Society of Medicine. Of a quiet and unassuming disposition, he thought and read deeply in science and philosophy, applying his knowledge to his profession with great success. He was especially noted for his kindness to the poor of the hospitals at which he worked. He leaves a widow and three children.

Dr. EVAN J. GRIFFITHS, who died at Porthcawl on June 5th, aged 58, was a native of the Swansea district. He received his medical education at the University of Edinburgh, where he graduated M.B., Ch.B. in *1904*; he obtained the *D.P.H.* Wales in *1910*. After graduating he became assistant to Dr. Jones of Penrhiwceiber, and was subsequently appointed medical officer of health for Pontypridd, which office he retained for eighteen years, retiring to Porthcawl some four years ago. During the war Dr. Griffiths served in East Africa, and also accompanied an expedition to North Russia. He leaves a widow and two children. The funeral at Glyn Taff Cemetery was attended by a large and representative gathering.

Dr. J. HAYDN TIMOTHY died on May 27th, after only three days' illness, at the age of 53. Educated at Llandovery College, Cardiff Medical School, and University College Hospital, London, he obtained the diplomas of M.R.C.S. and L.R.C.P. in 1903. After a period as resident medical officer at Fulham Infirmary, he took up practice at Nantgaredig, Carmarthenshire, where he remained until 1919, when he removed to Gwaun-cae-Gurwen, Glamorgan. He was a member of the British Medical Association, and had served on the Glamorgan Panel Committee for many years. Dr. Timothy's genial disposition assured him a large circle of friends among patients and colleagues in the area. He was buried at Nantgaredig on May 29th, and the large gathering at the funeral, both at Gwaun-cae-Gurwen and at Nantgaredig, testified to the esteem felt for him in both areas in which he had practised. He leaves a widow, one son, and two daughters.

Dr. WILLIAM LLEWELYN JONES, J.P., died at Merthyr on May 20th at the age of 58. He studied medicine at Glasgow University, where he graduated M.B., C.M. in 1893, and M.D. in 1900; he obtained the F.R.C.S.Ed. in 1901. After spending about twelve months in the East as a ship surgeon in a P. and O. boat, he went into practice with his eldest brother at Blaenavon. He finally settled down in practice in Merthyr, where he was surgeon to the Merthyr General Hospital. He had not been in good health since the death of his wife, about six years ago, and of his son, aged 9, who died some time later. He is survived by two daughters.

Universities and Colleges

UNIVERSITY OF OXFORD

Sir Wilmot Herringham, K.C.M.G., D.M., consulting physician to St. Bartholomew's Hospital, has been elected an honorary Fellow of Keble College.

UNIVERSITY OF CAMBRIDGE

At a congregation held on June 12th the following medical degrees were conferred:

M.D.—*S. M. Hattersley, *S. R. Prall.
M.B., B.CHIR.—G. L. Ormerod, N. H. L. Ridley.
M.B.—C. Arthur.
B.CHIR.—A. Barnsley.

*By proxy.

UNIVERSITY OF LONDON

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

The next series of eight lectures and demonstrations on tropical hygiene, which are intended for men and women outside the medical profession proceeding to the tropics, will be given by Lieut.-Colonel G. E. F. Stammers from July 6th to 10th next. These courses of instruction, in addition to providing simple rules for guidance in regard to preparation for life in the Tropics and personal hygiene, will also embrace a short account of some of the more common diseases, with advice in regard to measures of protection and some guidance in simple methods of self-treatment. The synopsis and other particulars can be obtained from the secretary, London School of Hygiene and Tropical Medicine, Keppel Street, W.C.1.

VICTORIA UNIVERSITY OF MANCHESTER

Dr. Stephen Leonard Baker has been appointed Procter Professor of Pathology and Pathological Anatomy, in succession to Professor J. Shaw Dunn; he will take up his new duties on September 29th.

UNIVERSITY OF BRISTOL

The following candidates have been approved at the examinations indicated:

M.D.—S. Datta.

FINAL M.B., CH.B.—*(Part I)*: H. M. F. Finzel (with distinction in Materia Medica, Pharmacy, Pharmacology and Therapeutics, and Forensic Medicine and Toxicology), J. J. Kempton, R. L. Marks. *(Part II)*: Elizabeth S. G. Owen (second-class honours), L. P. Ashton (distinction in Surgery and Obstetrics), J. E. Brown, L. R. Jordan (distinction in Medicine), R. H. Moore. *Group II (Completing Examination)*: Evelyn M. D. M. Collinson, Rowena M. Hickman. *Group I only*: W. A. F. Taylor. *Group II only*: O. J. P. Bollon.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

An ordinary Council meeting was held on June 11th, when the President, Lord Moynihan, was in the chair.

Presentation of Gold Medal

Mr. G. Buckston Browne was introduced, and the President presented him with the Honorary Gold Medal of the College, together with a document declaratory of its award to him, in recognition of his valuable contributions to surgery and of his great liberality in the endowment of an Institution for Surgical Research.

The late Sir Herbert Waterhouse

The secretary reported the death, on May 23rd, of Sir Herbert Furnivall Waterhouse, past member of the Council and of the Court of Examiners. A resolution of condolence was passed by the Council.

Fellowship

Diplomas of Fellowship were granted to the following forty-five candidates:

S. Riddiough, Edith M. Hall, R. G. Maliphant, J. Gabe, V. M. Albuquerque, G. N. Golden, A. W. Kendall, R. A. King, B. M. Sundaravadanan, A. J. W. Chamings, M. Coleman, T. R. Stevens, A. J. Watson, W. J. Wilkin, S. M. Cohen, J. M. Gibson, Beatrice M. Willmott, A. R. Banham, R. K. Bowes, G. Herbert, M. A. E. Anous, S. Ahmad, B. C. Rennie, C. B. Melville, Joyce R. Woods, B. Willis, A. H. Lendon, J. A. R. O'Regan, M. Backwell, G. H. Brandis, K. B. Bridge, H. A. Brittain, E. L. Button, I. A. Hamilton, H. D. Isaacs, J. Kelly, M. L. Kennedy, A. L. Kerr, S. N. Lytle, G. A. Mason, J. H. O'Donnell, C. M. Smithies, G. G. Talbot, T. Thornton, W. K. Welsh.

Primary Fellowship Examination

The following fifty-six candidates, out of 169 entries, were approved at the recent Primary Examination for the Fellowship:

F. W. Allinson, S. O. Aylett, J. E. M. Ayoub, P. S. Bassalvi, Diana J. K. Beck, D. L. C. Bingham, E. W. Bintcliffe, Edith J. R. Browne, K. L. Buxton, W. G. Campbell, S. G. Clayton, Gladys E. Clyne, E. A. Danino, G. B. Davis, Rosalind M. S. Derham, K. C. Eden, G. C. Ferguson, W. J. L. Francis, P. E. Glynn, W. H. Graham, T. F. R. Griffin, J. O. Harrison, H. E. James, E. C. Janes, E. J. Javeri, J. H. Kellgren, H. Kelson, C. A. Keogh, B. Kettle, S. Krantz, A. F. Lasrado, N. J. Logie, C. J. Lord, D. McMillan, C. P. Malley, J. A. Martinez, W. Merrington, S. N. Mistri, G. A. G. Mitchell, A. J. Moffett, K. G. Munsif, F. D. Murphy, R. P. Osborne, B. H. Page, C. G. Patel, E. E. Price, R. S. Richmond, N. W. Roberts, G. S. Robinson, M. D. Sheppard, M. A. H. Siddiqi, C. B. Singh, U. P. Sinha, E. C. N. Strong, W. D. Walker, Maureen D. Willmott Evans.

Membership

Diplomas of Membership were granted to the following candidates, who have now complied with the regulations:

P. Chandra, Hilary S. M. Hadaway, T. Standring.

Examiners

Mr R. M. Vick was elected a member of the Court of Examiners in the vacancy occasioned by the retirement of Mr. Rawling.

The following examiners were elected for the ensuing year:

Dental Surgery (Surgical Section): L. B. Rawling, H. S. Clogg, Russell J. Howard, Gwynne E. O. Williams, John Murray, C. E. Shattock, C. P. G. Wakeley.

Fellowship (Anatomy): P. N. Blake Odgers, *William Wright, J. E. S. Frazer, J. Basil Hume. *(Physiology)*: C. A. Lovatt Evans, R. J. S. McDowall, John Mellanby, *G. A. Buckmaster.

Under Conjoint Board:

Elementary Biology: J. P. Hill, T. J. Evans, G. P. Mudge, C. C. Hentschel. *Anatomy*: R. B. Green, W. E. Le Gros Clark, H. A. Harris. *Physiology*: E. B. Verney, H. Hartridge. *Midwifery*: T. B. Davies, A. W. Bourne, S. Forsdike, L. C. Rivett. *Pathology*: C. H. Fagge, C. E. Shattock, W. Bulloch, R. G. Canti. *Diploma in Public Health (Part I)*: J. W. H. Eyre. *(Part II)*: C. W. Hutt. *Diploma in Tropical Medicine and Hygiene (Part I)*: D. S. Harvey. *(Tropical Medicine and Tropical Hygiene)*: G. Carmichael Low. *Diploma in Ophthalmic Medicine and Surgery (Part I)*: W. S. Duke-Elder, C. B. Goulden. *Diploma in Laryngology and Otology (Part I)*: W. G. Howarth. *(Part II)*: R. Affleck Greeves. *Diploma in Psychological Medicine: Diploma in Gynaecology and Obstetrics*: J. D. Barris. J. G. Greenfield. *Diploma in Laryngology and Otology (Part II)*: W. M. Mollison, Norman Patterson.

Examiners for Australia and Canada.

The Macloghlin Scholarship

Ten candidates were nominated to compete at the pre-medical examination in chemistry and physics beginning on June 30th for the Macloghlin Scholarship.

The Buckston Browne Surgical Research Farm

The ceremonial laying of the foundation stone of the Buckston Browne Surgical Research Farm at Downe, Kent, will take place on July 8th.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND

At the monthly business meeting of the College held on June 5th, the following successful candidates were duly admitted Licentiates and Members of the College: A. J. P. Alexander, A. G. Thompson, H. L. Chopra.

The representative of the College on the Irish Medical Council reported on the recent proceedings of the Council.

A letter was read from the presidents and trustees of Lakeside Hospital, Cleveland, U.S.A., inviting the College to be represented at the dedication of the hospital on June 17th.

The Services

On June 8th Surgeon Rear-Admiral Reginald Bond, C.B., had the honour of being received by His Majesty at Buckingham Palace upon his appointment as Medical Director-General of the Navy.

FLORENCE NIGHTINGALE MEDAL

On the afternoon of June 29th, at Bedford College, Sir Arthur Stanley, chairman of the British Red Cross Society, will present to Dame Anne Beadsmore Smith, D.B.E., R.R.C., the International Red Cross Committee's Florence Nightingale Medal. This is awarded annually to the six most deserving nurses selected by the International Red Cross Societies. Dame Anne Beadsmore Smith, who has been matron-in-chief of the Territorial Nursing Service since 1925, served with the Forces throughout the South African war, and was principal matron in France and Malta in Queen Alexandra's Imperial Military Nursing Service from 1914 to 1917, and matron-in-chief of the Q.A.I.M.N.S. at the War Office from 1917 to 1924.

DEATHS IN THE SERVICES

Major Ulick Joseph Bourke, Indian Medical Service, died at Gaya on May 7th, aged 45. He was born on May 12th, 1885, the elder son of Lieut.-Colonel U. J. Bourke, R.A.M.C. (ret.), was educated at Glasgow University and the London Hospital, and took the Scottish triple qualification in 1910. He joined the R.A.M.C. as a temporary lieutenant on January 21st, 1915, took a permanent commission in the I.M.S. on May 30th, 1916, and became major on January 21st, 1927. During the war he served in France and Belgium in 1914-15. In Iraq 1917-18, and in Macedonia in 1918. For the last two years he had held the post of superintendent of Gaya Central Jail.

Lieut.-Colonel Edward Reginald Johnson, Bengal Medical Service (ret.), died in Kensington on May 15th, aged 85. He was born on January 23rd, 1846, the son of William Johnson, Esq., land surveyor, of Stretford. Manchester, was educated at Bart's, and took the M.R.C.S. in 1867 and the L.R.C.P.Ed. and L.S.A. in 1868. Entering the I.M.S. as assistant surgeon on October 1st, 1868, he became surgeon-major after twelve years' service, and brigade surgeon and lieutenant-colonel on October 1st, 1893, and retired in 1894. He served on the North East Frontier of India in the Lushai campaign of 1871-72, when he was mentioned in dispatches, and received the frontier medal with clasp, and in the Akha campaign of 1883-84, when he was again mentioned in dispatches, but no medal was given for that campaign.

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

The House of Commons was occupied this week with the Committee Stage of the Finance Bill. Mr. Snowden promised to put down for the Report Stage an amendment exempting from the Land Values Tax all lands owned or occupied by charities for the purpose of the charity or held by them to provide funds for the same purpose. Charities so exempted would include those for the advancement of education and for other purposes beneficial to the community. It will be remembered that the Finance Bill as introduced proposed to exempt the sites of hospitals, but not other property owned by them.

No progress has been made in the Commons with the Pharmacy and Poisons Bill or the Proprietary Medicines Bill.

The House of Lords has read the Representation of the People Bill a second time.

In the House of Lords, on June 16th, Lord Ponsonby moved the second reading of the Bethlem Hospital (Amendment) Bill. He said that the Bill was necessary to enable Bethlem Hospital to be used for the Imperial War Museum. It was proposed to use the centre part of the building, which contained the dome, as the war museum. The rest of the site would remain in the hands of the London County Council as a garden and open space. The Bill was read a second time.

National Insurance Pharmacists

On June 9th Colonel HOWARD-BURY asked if the Government had come to a decision on the proposal to introduce legislation to repeal the section which prohibited insurance chemists from giving an insured person an inducement by gift or otherwise in consideration of his presenting an order for drugs or appliances on a national health insurance form. Miss LAWRENCE replied that legislation was not necessary to deal with this point, but an appeal had been made against a recent decision of the Courts in the matter. Until that appeal had been heard, the Minister of Health could not properly make any statement.

Post-Vaccinal Encephalitis

Mr. GREENWOOD, on June 9th, informed Mr. Freeman that an antivaccinal serum had been made available and had been employed by the medical attendant in those cases of suspected post-vaccinal encephalitis which had been reported since the second report of the Rolleston Committee, and of which sufficiently early information had been received.

Juvenile Mental Defectives in Scotland

Mr. WESTWOOD, replying to Mr. Sinkinson, on June 16th, said that the duty imposed on educational authorities in Scotland by the Mental Deficiency and Lunacy (Scotland) Act, 1913, to ascertain what children residing within their areas were mentally defective within the meaning of the Act and to make provision for the education of those who were capable of receiving benefit from special instruction, extended only to children between 5 and 16 years of age. According to the last return made by education authorities, the number of children between these ages who were ascertained by them to be mentally defective was 4,910, of whom 3,993 were ascertained to be educable, and 917 uneducable. The number of educable mentally defective children receiving instruction in schools and institutions was 3,938. Between the ages of 5 and 18, there were 192 educable and 696 uneducable mental defectives certified under the Act and in residence in certified institutions, and 110 uneducable mental defectives under guardianship in private dwellings. No mental defectives under 18 were in residence at the State institution.

Medical Referees: Workmen's Compensation Act

Mr. SHORT, on June 16th, informed Mr. Stephen that the total number of medical referees appointed under the Workmen's Compensation Act was 272. The preparation of a statement giving their names and the number of cases referred to each would involve considerable labour, which the Home Secretary, on the information before him, did not think would be justified. There were no records in the Home Office showing the number of cases which each medical referee certified as fit for light or ordinary work. Dr. FREMANTLE, on a point of order, suggested that to give the details which Mr. Stephen asked concerning medical referees would not be in the public interest.

Dental Benefit Schemes for Women.—In reply to Mr. Lovat Fraser, on June 10th, Miss LAWRENCE said the number of insured women members of approved societies and branches in England having schemes of dental benefit following the second valuation was approximately 4,250,000. The complete results of the third valuation were not yet available, but from the results already received it was evident that there would be a considerable reduction in the number of women entitled to dental benefit.

Dental and Ophthalmic Treatment.—Mr. GREENWOOD told Mr. John, on June 11th, that there was at present no proposal in contemplation to make dental and ophthalmic treatment statutory benefits for all members of approved societies under the National Health Insurance Acts.

Solitary Confinement.—Replying, on June 11th, to Mr. Freeman, Mr. CLYNES said solitary confinement in prisons had been abolished. The period of employment in separation was done away with altogether by his Prison Rules of April last. For breaches of prison discipline, prisoners were liable to be punished by close confinement, but after the first day on promise of good behaviour were allowed one hour's exercise daily and to attend chapel on Sundays. The modern tendency was to substitute loss of privileges for close confinement.

The Factory Inspectorate.—Replying, on June 11th, to Major Colville, Mr. CLYNES said that following the Departmental Committee's report on the Factory Inspectorate, the Government had decided to increase the general inspection staff from 180 to 243, the medical staff from 5 to 8, the electrical staff from 5 to 12, and the engineering staff from 6 to 10, these increases to be spread over a period of five years.

Imported Meat.—In reply to Sir Charles Cayzer, on June 11th, Mr. GREENWOOD said he had no information with regard to the amount of carton meat at present imported into this country. He had received representations with regard to this meat, and was considering them with certain other questions relating to the control of imported meat under the Public Health (Imported Food) Regulations.

Pensions.—Mr. ROBERTS, on June 15th, informed Mr. Jowett that of the 1,465 applications made under the over-seven-years' limit arrangement recognized for medical treatment or pension or pecuniary grant, in about 950 cases pension, or some addition to an existing pension, was granted, at an estimated cost of about £1,000 a week. The number of cases in which medical treatment only was found necessary was 39.

An All-in Insurance Scheme.—On June 15th Miss LAWRENCE told Sir G. Penny that the possibility of an all-in insurance scheme, including unemployment and health benefits and pensions, to be applicable to a large section of the population was considered by the Cabinet Committee set up to make a general survey of the national insurance and pensions schemes. The subject was dealt with in the committee's report, which was still under the consideration of the Government.

Statistics of Unidentified Bodies.—On June 16th Mr. CLYNES told Mr. Somerville Hastings that 1927 was the most recent year for which figures on the number of unidentified bodies taken to the mortuaries in London were available. Seventy-nine bodies of newly born infants and 74 other bodies found in that year remained unidentified two months after the end of the year. Those numbers fairly represented the yearly average.

Regulations for Patients in Military Hospitals.—Mr. SHAW states that only in exceptional circumstances are patients in military hospitals allowed to leave the grounds of the hospital. The number of ex-soldier patients from the war in military hospitals is practically negligible, and there is no sufficient reason for altering the existing rules as regards soldier patients.

Medical News

The annual dinner of the West London Medico-Chirurgical Society will be held at the Trocadero Restaurant on Wednesday, July 1st, at 7.30 for 7.45 p.m.

The annual dinner of the Cambridge Graduates' Medical Club will be held in Downing College on Friday, July 3rd, at 7.45 p.m., with Sir Humphry Rolleston, Bt., president of the club, in the chair. The annual meeting will precede the dinner at 7.15 o'clock. The honorary secretaries are Mr. Reginald Vick and Dr. F. G. Chandler.

At a meeting of the Society for the Study of Inebriety, to be held in the rooms of the Medical Society of London, 11, Chandos Street, Cavendish Square, W., on Tuesday, July 14th, at 4 p.m., Sir Malcolm Delevingne, K.C.B., Deputy Permanent Under-Secretary of State for the Home Office, will deliver an address on drug addiction as an international problem.

The annual general meeting of the Medico-Legal Society will be held at 11, Chandos Street, W.1, on Thursday, June 25th, at 8.15 p.m. This will be followed by an ordinary meeting, when Dr. T. H. Blench will read a paper on "Crime investigation in Paris," to be followed by a discussion.

At the next meeting of the Optical Society, to be held at the Imperial College of Science and Technology, South Kensington, on Thursday, June 25th, at 7.30 p.m., a demonstration will be given by Messrs. H. H. Emsley and E. F. Fincham on the anumbra prism ophthalmoscope.

The Royal Free Hospital, whose two most pressing needs at present are funds to complete the nurses' home and contributions to the general maintenance scheme, is much indebted to the generosity of Miss Ruth Draper in giving, at the Vaudeville Theatre, an extra matinée, with a special programme, for the hospital on June 30th, at 2.45 p.m.

The summer meeting of the Institution of Heating and Ventilating Engineers will be held at Harrogate from June 22nd to 24th. The agenda includes a paper by Mr. A. F. Dufton entitled, "Radiant heat: A contribution to the study of the heating of school buildings."

The forty-second Congress of the Royal Sanitary Institute will be held in Glasgow from July 4th to 11th; Sir Henry Mechan, the founder of the Chair of Public Health in the University of Glasgow, will preside. The subjects to be discussed in the Sections and conference cover a wide field, and include the role of the hospital relative to the development of preventive medicine, and the proposals of the British Medical Association for a general medical service. Dr. Walter Elliot, M.P., will deliver a lecture on "A continuous health policy" on Friday, July 10th. Over 920 delegates have been appointed from Government departments, the colonies, and some foreign nations, as well as 500 municipal authorities, societies, and universities. A health exhibition will also be open during the meeting.

Detailed information about the lectures and demonstrations arranged for next week by the Fellowship of Medicine and Post-Graduate Medical Association will be found at page 260 of the *Supplement*. The special evening lectures to candidates for the M.R.C.P. are being continued. Syllabuses and tickets for all the courses may be had from the Fellowship of Medicine, 1, Wimpole Street, W.1.

A series of weekly lectures on proctology has been arranged by the staff of St. Mark's Hospital, City Road, E.C.1. On Thursday, July 9th, Mr. Lockhart-Mummery will discuss perineal excision of the rectum, with cinematograph demonstration. Sir Charles Gordon-Watson will lecture on carcinoma of the colon on Thursday, July 16th. The injection treatment of piles will be the subject of a lecture by Mr. E. T. C. Milligan on Thursday, July 23rd, and Mr. W. B. Gabriel will speak on anal fissure on Tuesday, July 28th. The lectures commence at 4.30 p.m., and are open to registered medical practitioners free of charge.

The German medical authorities have recently established a wireless coastal station known as "Elbe-Weser-Radio," through which any ship can obtain medical advice, such calls for assistance being connected directly through the new station to the National Hospital at Cuxhaven.

A feature of the International Rotary Conference which is about to be held in Vienna will be a vocational meeting of Rotarian members of the medical profession from all parts of the world to be held in the house of the Gesellschaft der Aerzte. At this meeting Professor Wagner-Jauregg will give a twenty-minute lecture on the treatment of general paralysis by infection with malaria parasites. The lecture has been printed in three languages, and is to be distributed in advance to medical members of the conference.

The international exhibition of hygiene at Dresden has been reopened from May 15th until September 30th.

A statue of the celebrated histologist Professor Ramon y Cayal was recently unveiled in the courtyard of the Madrid Faculty of Medicine.

Professor Fritz Lange of Munich has been made an honorary member of the British Orthopaedic Association.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are *MUSEUM* 9861, 9862, 9863, and 9864 (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediocra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS

Pyrexia after Confinement

"J. D." writes: A young woman has been running a temperature nightly of 101° to 103° F. since her confinement a month ago. A consultant surgeon has diagnosed mild endometritis and advised quinine and iron, but the patient gets weaker. Can anyone suggest what should be done either to make an exact diagnosis or by way of treatment?

Urticaria

"PRACTITIONER" (Scotland) writes: Can any reader suggest a remedy for urticaria in a very nervous woman, aged 44; duration about two years? Apart from her nervous symptoms, menopausal changes, and haemorrhoids, she is a healthy woman. She has been treated in hospital and in nursing homes (under skin specialists) with everything worth trying—for example, calcium by every method and preparation, adrenaline, pituitrin, bowel irrigation, streptococcal vaccines, etc. The vaccine at first seemed to help a little. Diet has no effect. The urticaria affects arms, body, and face, and to a slight extent the buccal mucous membrane, and recurs every two or three days.

Diabetic Diet on Holiday

Dr. R. H. BLACKBURN (Preston) writes: I wonder if any reader could tell me where a diabetic (a working man) could spend a holiday without the worry of providing his own dietary? The ordinary boarding establishment does not welcome, or cater for, the diabetic, and this man has his holiday spoiled by having to plan and provide his meals. In a strange place, too, it is especially difficult.

Scleroderma with Pernicious Anaemia

Dr. J. BARCROFT ANDERSON writes with reference to the query under this heading (June 6th, p. 1007): Dr. Alex. Patton has omitted to state whether he has excluded pellagra as a possible cause of his patient's illness, and whether he has detected excessive sugar tolerance.

Income Tax

New Practice—Basis of Assessment

"H. C." bought his practice as from April, 1930, and has made his declaration of the profits for 1930-31 on the basis of his cash receipts less expenses. The inspector claims to charge tax on the amount of the bookings, leaving the question of bad debts over until next year. Prior to April, 1930, "H. C." was doing locumtenent work, and used an M.C. 2-seater. He sold that car for £55 and bought a saloon for £290. What should he claim?

*** Income tax is charged on full profits, and not merely on that portion of the profits which has been realized. The cash basis, therefore, cannot be claimed as a right, and in the first year of a practice is unfair to the Revenue, because a full year's expenses are thereby charged against something less than a full year's income. On the other hand, some allowance should be made for probable loss by bad debts. "H. C." should prepare a careful statement setting out a list of the outstanding debts as at April, 1931, and indicate against appropriate items the probable loss through non-payment in each case. The total of these deductions should then be claimed as a set-off from the gross bookings as a specific reserve for bad and doubtful debts. With regard to the car, we consider that "H. C." should be allowed 15 or 20 per cent. of the £290 in respect of depreciation. Such an allowance excludes a renewal claim, but, as the saloon car was purchased in connexion with the new practice, it is doubtful if a renewal or obsolescence claim could properly be made, especially as there was a change in the category of assessment—namely, from assistant to principal.

Proportion of Household Expenses

"C. F. E." explains that he occupies a two-story house in a provincial town, and keeps two maids. The rooms used professionally—on the first floor—are consulting room, secretary's filing room and waiting room, and combined waiting room and dining room, and garage.

*** It is, of course, impossible to do otherwise than try to arrive at a fair approximation—precise calculations are impossible. We think that on the facts stated "C. F. E." should be reasonably satisfied with a compromise on the basis of one-half the Schedule A assessment, rates and repairs, one-third of the cost of lighting and heating, and cost of board, wages, and laundry of one maid,

LETTERS, NOTES, ETC.

Rupture of the Tendons

Mr. HARRY PLATT, M.S., F.R.C.S., writes: May I remedy an omission in my letter in last week's *Journal*? Lines 4 and 5 should read: "I have operated on a professional footballer who had sustained *a complete rupture of the Achilles tendon accompanied by a complete rupture of the plantaris. . . .*"

Chromium Plating

Mr. FRANK MASON, A.M.I.E.E. (managing director of Stainless Plating, Ltd., Sheffield), sends the following note arising out of the correspondence on chromium plating published in our issues of May 9th and 16th: Since the elimination of such culture grounds as are provided by polishing pastes, etc., in crevices is of special interest to both physician and surgeon, the installation of properly chromium-plated metal parts would appear to be of the greatest importance, and incidentally would save much time and money. No polishing whatever is required, and the mere wiping off of all extraneous matter, as one would from a dinner plate or a glass window, is all that is required. Further, because of its extreme hardness, no fear need be entertained of the chromium wearing through by hard rubbing, as in the case of nickel or silver plating. Unfortunately, all processes and operators do not produce the same results. Nevertheless, chrome-plated articles, when properly made and treated with reasonable care, whether they be taps and rails, or sterilizers and the like, will retain their original beauty of colour and polish almost indefinitely. Examples can be seen in many hospitals and similar institutions, as well as in private practice, where fittings have been installed for more than five years and are as good to-day as when fixed. At the Middlesex Hospital some of the chrome-plated fittings have been in use for over two years; they range from the largest sterilizer to the humble screw.

Cave-dwellers of Derbyshire

Dr. J. S. MANSON (Warrington) writes: The excellent summary of Mr. A. Leslie Armstrong's lecture to the Warrington Division in your issue of June 6th (p. 998) omits reference to the most important discovery yet made by him in the exploration of the Pin Hole Cave. This was a portion of a rib of a reindeer, on which was engraved a human figure representing a man with a mask in a dancing posture. This find is unique in English archaeology, and as an example of Aurignacian culture brings this cave into line with the classic caves of Aurignac in France and Altmira in Spain. Readers of the summary not yet aware of this discovery will appreciate, I am sure, the significance of this specimen of Upper Palaeolithic culture in England. There is a slight error in the eighth line of the summary: "Marlborough" should be "Harborough."

Sight Test for Motorists

We are informed that the Automobile Association is appealing against the recent decision of the Divisional Court concerning motorists who are unable to read a number plate at twenty-five yards. The Divisional Court decided that there was no right of appeal against the refusal of the licensing authority to grant a driving licence. It is the contention of the A.A. that, under Section 5 (Subsection 5) of the Road Traffic Act, motorists have a general right of appeal, and the present action is being taken in the interests of motorists who, though unable to read the letters or figures on a number plate at twenty-five yards, have driven for long periods without accident or infraction of the law.

Medical Golf

At the summer meeting of the Shropshire Medical Golf Association, held on May 31st at Church Stretton, deep regret was expressed at the recent death of Dr. George Higginson, who had not missed a meeting since the association was founded in 1919. The winner of the association's Challenge Bowl was Dr. Harker of Oswestry, whose score was 67 net (77–10). The Foursomes versus Bogey Competition resulted in a tie between Drs. Beckett and Richardson and Dr. J. C. Davies and Mr. A. Lavelle (1 up). Arrangements were made for holding the next meeting at the Wrekin Golf Club on the second Sunday in October.

The spring meeting of the Sussex Medical (B.M.A.) Golfing Society was held at the new course of the West Sussex Golf Club at Storrington. Twenty-four members were present. On the morning round the Challenge Cup was won by Dr. A. E. Drynan (78 net). In the afternoon Drs. F. Heckford and J. K. Raymond won the four-ball foursome against bogey (2 up).

A Disclaimer

Dr. W. ANNANDALE TROUP writes: It has been brought to my notice that a large number of booklets containing my views on the titanium alloy arc, accompanied by an advertisement of a certain apparatus, have been circulated widely among the profession. I would like it to be made perfectly clear that this was done without my knowledge and without my consent.

Surgery and Diet

We regret that the name of Professor S. B. Wolbach of Harvard was wrongly spelt in Colonel McCarrison's first lecture (published on June 6th, p. 966), and in our leading article on June 13th (p. 1031).

Vacancies

Notifications of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 50, 51, 52, 53, 54, 55, 56, 57, 60, and 61 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 58 and 59.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 259.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

584 Dissecting Aortic Aneurysm Simulating Pulmonary Neoplasm

A. CLERC, P. N. DESCHAMPS, and R. SCHWOB (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, March 2nd, 1931, p. 280) describe the case of a woman, aged 53, who had experienced for two months stabbing pains in the left side of the chest. The patient was cachectic and moderately dyspnoeic. Examination revealed dullness, diminished fremitus, and weak breath sounds over the left base, and extending up to the mid-scapular region. No physical signs were found in the cardio-vascular system. Radioscopy showed a concise rounded shadow almost filling the left side of the chest and separated from the clavicle and the diaphragm by narrow zones of normal density. Exploratory puncture produced a brownish haemorrhagic fluid, and a diagnosis of pulmonary neoplasm was made. During succeeding months the signs became more marked, and a horizontal zone of tenderness extended across the left breast and axilla. A further puncture withdrew sero-fibrinous fluid. Following an acute onset of respiratory symptoms with fever, death ensued ten months after the beginning of the illness. At the necropsy there was found a small purulent effusion in the left pleural cavity. The left lung was flattened, and formed a thin layer surrounding a large mass which appeared to extend from the mediastinum, and which contained degenerated blood clot. The aorta, arising from a small heart, was widened and atheromatous, and extended only as far as the transverse arch, where it merged with the mass, which was evidently a dissecting aneurysm. The authors remark that while in this case the signs justified a diagnosis of pulmonary neoplasm, it occasionally happens that a lesion having all the appearances characteristic of aneurysm is found at necropsy to be a new growth. Absence of pulsation on screening a mediastinal mass is in favour of the existence of aneurysm rather than a contraindication of it.

585 Anal Chancre

A. A. LANDSMAN (*Med. Journ. and Record*, April 1st, 1931, p. 328) believes that anal chancre occurs more frequently than has been stated by various authorities, and records three cases. The diagnosis has to be made from simple fissure—an acutely painful but clean surgical lesion, except when local infection occurs. A fissure is single, and is situated usually in the posterior median line; ulceration, excoriation, and discharge are rare unless there has been previous rectal disease. On the other hand, chancre has a less acute onset, and its course is more chronic. There may be multiple lesions which are not in the median line, with dermatitis, superficial anal ulceration, and a peculiarly fetid serous discharge. Spirochaetes may be found on dark field examination. The inguinal glands are enlarged and tender. The Wassermann reaction may be negative until secondary symptoms occur. Landsman failed to find any induration of the base of the chancre, such as occurs in the genital chancre, or condylomata. The serious nature of chancre and the possibility of syphilis being communicated to others render the differential diagnosis and subsequent treatment of the utmost importance.

586 Direct Transmission of Herpes Labialis

Despite the numerous observations and experiments of recent years on the infective nature of herpes simplex, there is as yet no evidence that in the human subject it is normally spread by direct contagion, though in the case of herpes labialis opportunities for such spread must be very frequent. K. SCHEER (*Münch. med. Woch.*, April 10th, 1931, p. 613) records that, of his own two children, the boy suffered from periodic attacks of herpes labialis, usually on the lower lip, while the girl had never suffered from herpes. In December, 1926, she had typical bilateral herpes zoster on the back, and two days afterwards the boy developed varicella. There was thought to be an association between the two conditions, but fourteen days later still the girl, whose herpes had now healed, also developed varicella. In May, 1930, the boy, who was suffering from one of his periodic attacks of herpes labialis, bit his sister on the chest in the course of a bedtime scuffle. The teeth marks were definite, and pigmentation of the area was still present when, eighteen days later, a typical herpetic eruption developed at the site of the bitten skin. The author comments that the incubation period here was longer than that which has been recorded in the experimental transmission of herpes.

587 A Confirmatory Physical Sign in Ascites

As a confirmatory diagnostic sign of ascites, J. T. WITHERSPOON (*Journ. Amer. Med. Assoc.*, March 21st, 1931, p. 944) suggests that in such cases, when one side of the abdomen is tapped with the finger and the other side is auscultated, two sounds similar in timing to normal heart sounds are heard. The first is caused by transmission of the sound wave through the fluid; the second is the result of the fluid wave crossing the abdomen and striking the auscultated side. This sign was present in 18 cases of ascites examined, and was confirmed by abdominal aspiration, operation, or necropsy. It was not present in cases in which the usual physical signs were absent, nor in abdomens markedly distended with gas.

588 Ocular Manifestations of Syphilitic Serous Meningitis

J. ROLLET and PAUFIQUE (*Journ. de Méd. de Lyon*, March 20th, 1931, p. 193) state that syphilitic serous meningitis occurs mainly in young infants, in the congenital, and in the secondary or tertiary stage of acquired syphilis. Records of the pathology are few, since most cases are cured, but there may be an ependymitis or internal hydrocephalus, a diffuse serous meningitis, a mixture of these, or a localized cortical or basal meningitis. Prodromal symptoms include headaches, nausea, constipation, buzzing in the ears, and pseudo-migrainous attacks; these are followed by violent headaches, vomiting, obstinate constipation, and a slow pulse, with no great change in the general condition, no meningeal symptoms, and no pyrexia. The ocular signs which dominate the clinical picture, and are diagnostic, are papilloedema (the measurement of which is of no diagnostic importance), indications of intracranal hypertension, shown by hypertension in the central retinal artery, bilateral mydriasis, and paresis of the sixth cranial nerve. The visual acuity long remains normal, a change in the fields indicating an intracranial tumour. There may be associated syphilitic ocular lesions, or general signs of the disease. The cerebro-spinal fluid is under pressure without cytological modification. The prognosis is good with early diagnosis, and the treatment should include frequent lumbar puncture, the exhibition of hypertonic solutions, and the administration of antisyphilitic remedies.

589 Measles Encephalitis

E. C. BENN (*Brit. Journ. Child. Dis.*, January–March, 1931, p. 22) reports two fatal cases of measles encephalitis. The first, which occurred in a previously healthy girl, aged 8, with no history of fits or convulsions, was unusual in that the symptoms of encephalitis appeared on the third day of measles, within twenty-four hours of the eruption, and after an apparently normal onset of the disease. Death ensued within twenty-four hours of the first sign of cerebral involvement. The second patient was a boy, aged 5, who had had no previous illnesses. On the eighth day of an ordinary attack of measles, when he was already convalescent, he developed symptoms of cerebral

involvement, and death followed in twenty-five hours. Both patients showed symptoms of severe and widespread cerebral damage, and the prognosis was hopeless from the first. Post-mortem examination in both instances revealed *acute congestion of the brain on naked-eye examination*, and the typical histological appearances of post-infective encephalitis.

590 Streptococcal Myositis

F. E. BICHARA (*Thèse de Paris*, 1931, No. 10), who records 19 illustrative cases in patients aged from 9 to 68, 13 of which were fatal, states that the most typical form of streptococcal myositis is characterized by a sudden onset, a very grave general condition from the first, and a rapidly fatal course. The only clinical manifestation of the septicaemia is myositis involving one or more muscles, and manifested by a considerable but variable swelling. The muscle is infiltrated with serous fluid swarming with streptococci, and the histological lesions are those of degenerative myositis. In addition to the hyperacute form of streptococcal myositis, there is a variety found in the course of well-defined streptococcal infections such as erysipelas, puerperal fever, ulcerative endocarditis, and Osler's disease. Abortive and curable forms may occur in which the infection of the muscle is due to a special form of streptococcus.

591 The Lungs after Measles

J. L. KOHN and H. KOIRANSKY (*Amer. Journ. Dis. Child.*, March, 1931, p. 501) had previously found that skiagrams of the chest taken during measles in 130 children showed shadows suggesting pulmonary infiltration in 62.4 per cent. of those under 4 years old and in 42.2 per cent. above that age. They now report their observations on re-examination of these children from six to ten months after measles. The results were as follows. Little or no residual changes were found at the site of previous pulmonary infiltrations, even when they had been extensive and of long duration. On the other hand, the evidence of pleural involvement during measles was striking. In 18 children, most of whom had been in good health on discharge from hospital, pleural thickening not present during measles was now seen at the site of the interlobar fissure between the upper and middle lobes of the right lung, or in some other portion of the pleura. The pleurisy often occurred in cases regarded clinically as mild.

Surgery

592 Ankylosis of the Temporo-maxillary Joint

M. COELST (*Rev. de Chir. Plast.*, April, 1931, p. 63) describes a case of temporo-maxillary ankylosis on the right side which occurred in a young woman, aged 22. Various methods of treatment which had been tried for three years had failed, and at the time of the surgical intervention it was impossible for the patient to separate the molar teeth even to a slight degree; this made the taking of sufficient nourishment extremely difficult. On the right side, a little in front of the temporo-maxillary articulation, there were numerous scars of fistulae resulting from the arthritis which was the original cause of the lesion. The operation was conducted under general anaesthesia; a V-shaped incision was made, the point of which reached up to the level of the ear, care being taken to avoid the facial nerve. The outer surface of the joint was exposed and freed. A gouge was then used for hollowing out a thin section of bone at the site of the original articular surface. A true resection of bone was not performed, but the articular surfaces were shaped by means of a file. At the end of the operation the patient could open and close the jaws like a normal subject. An apparatus was fitted a few days later to enable the movements of the jaws to be carried out passively daily, and to prevent any risk of a return of the ankylosis. Three months later the scar was practically invisible; the general condition of the patient was much improved, and the mouth could be opened normally.

593 Lingual Tuberculosis

According to CH. DU BOIS (*Rev. Méd. de la Suisse Romande*, April 25th, 1931, p. 257) the symptomatology of the chief forms of tuberculosis of the tongue corresponds almost exactly to that of the different cutaneous types. Lingual lupus and tuberculous gummata are rare; both evolve very slowly, and are generally found on the dorsum. The former is usually associated with lupus in other parts of the mouth, and rarely ulcerates. The late ulceration of tuberculous gummata distinguishes them from the syphilitic forms, though serological tests are often necessary for diagnosis. Spontaneous primary and secondary ulcerations are the commonest of the lingual types; exceptional in infancy and old age, they occur more frequently in men than in women. Primary ulcerations are of two varieties, one being caused by accidental infection in a subject free from tuberculosis, and the other being due to auto-infection in a tuberculous patient. Secondary ulcerations arise without any previous traumatism or gummatous formation. Both types usually occur on the tip or edges of the tongue. At their onset these ulcerations cannot be distinguished from simple erosions, their general starting-point, but any failure to heal after removal of the cause of injury, such as a jagged tooth, is rather indicative of tuberculosis. Lingual tuberculosis must be differentiated from syphilis and cancer; a case is recorded which illustrates the difficulty of diagnosis. The treatment employed by Du Bois is the application of caustics and x rays. Excision of small areas, as in cutaneous tuberculosis, may prove efficacious. Prophylactic measures consist chiefly in maintaining the integrity of the organ.

594 Fatal Thyroid Crisis following Injection of a Varicose Vein

E. I. GREENE and J. M. GREENE (*Journ. Amer. Med. Assoc.*, February 21st, 1931, p. 611) report the case of a man, aged 40, who had had the typical signs of Graves's disease for eight months. In the region of the left ankle there was a small ulcer, with a number of small veins at its upper margin. On account of pain in the ulcer he asked to have the veins injected. This was refused, but he was advised to enter hospital for treatment for his thyrotoxicosis, and, incidentally, for his ulcer. He persuaded another physician to perform the injection, but within a few hours severe pain developed at its site, and later there ensued restlessness, profuse sweating, vomiting, and diarrhoea. Two days later he was delirious, with marked exophthalmos and hyperpyrexia, and there was extravasation of the injected material at the upper border of the ulcer. In spite of treatment with the compound solution of iodine through a stomach tube, sodium iodide, intravenous injections of 1 per cent. dextrose in normal saline solution, and morphine in 1/4 grain doses, the patient died. The authors comment on the vital necessity of refraining from all operative procedures in such cases until the thyroidism has been brought under control.

595 Carcinoid Tumours of the Small Intestine

H. H. COOKE (*Arch. of Surg.*, April, 1931, p. 568) records eleven cases of carcinoid tumours of the small intestine, and, as metastasis was present in three cases, the series is divided into a malignant and a benign group. Carcinoid tumours of the small intestine usually appear as small circumscribed firm nodules, which project into the lumen and are often multiple. Their size varies from 3 mm. to 1 cm. or more in diameter, the larger nodules being yellow to greyish-white in colour. Their free surfaces are usually covered by normal mucosa, but there may be superficial erosions or ulcerations. The primary nodules have the consistency of a hard fibroma. Carcinoid tumours may occur anywhere in the gastro-intestinal tract, but are most common in the appendix and small intestines. Their origin has been assigned to the principal epithelial cells of the crypts of Lieberkühn, to Paneth's cells, and to the basal granular cells. In the eleven cases under review intestinal obstruction was caused in three of the malignant and in one of the benign cases. Five of

the patients were in the seventh decade of life. The primary lesion was a single circumscribed nodule in seven cases, multiple nodules in three cases, and an annular constriction in one case; it was situated in the jejunum in two cases, and in the ileum in 9 cases, the size of the lesion varying from 0.2 cm. to 2 cm. in diameter. The only treatment for carcinoid tumours is surgical removal, the prognosis being favourable in the absence of metastasis.

596 Spina Bifida Treated by Operation

C. LASSERRE and P. LÉONARD (*Bordeaux Chir.*, April, 1931, p. 169) report a case of spina bifida which was treated surgically ten hours after the birth of the infant. The father was under treatment for syphilis; when it was recognized that the mother was pregnant she received injections of bismuth and also of acetylarsan. After a normal but slightly premature confinement a male child was born which showed signs of a prominent forehead and had a reddened zone in the lumbar region. This increased in size as the child moved and cried, until it was as large as a small orange, and revealed through a thin covering of skin that it was filled with a clear liquid. There were no signs of hydrocephalus or club-foot, and no contraindications to operation. This was immediately performed, and consisted in opening the sac, evacuating the fluid, and reducing the nerve elements. The sac was dissected out and sutured over the nerves, and the skin and underlying tissues were sutured over the opening in four layers. During the operation the child was laid prone on his abdomen. There were no post-operative complications, but antisyphilitic treatment was given. On the eighth day signs of hydrocephalus were evident, but were not progressive.

Therapeutics

597 Trichlorethylene in Trigeminal Neuralgia

It was noted during the war that workers with trichlorethylene developed symptoms of acute poisoning—namely, bilateral loss of sensation definitely confined to the trigeminal distribution of the face. Plessner and Oppenheim were therefore led to try the efficacy of the drug in trigeminal neuralgia, using the inhalation method. M. A. GLASER (*Journ. Amer. Med. Assoc.*, March 21st, 1931, p. 916) now records the results obtained in 15 cases; 13.3 per cent. were partially relieved, contrasting with Seelert's claim that 74 per cent. of his patients improved. Though later reports do not fulfil the earlier expectations for this treatment, Glaser considers that trichlorethylene, which is non-toxic, is an extremely valuable adjunct in the treatment of trigeminal neuralgia, and should be tried in all cases before resorting to alcohol injections or surgery. It is ideal when effective, since the pain is relieved without anaesthesia resulting. Its action is unknown. The drug should be inhaled three or four times daily; twenty to twenty-five drops are placed on a piece of gauze, and the inhalation is continued till the odour has entirely disappeared. This procedure should be continued for four to six weeks, but after the pain has been relieved daily inhalations are unnecessary. As a prophylactic, the drug may be inhaled every two or three months for three consecutive days. As trichlorethylene occasionally produces vertigo, sleep, and drowsiness, it should be inhaled in a recumbent posture. It also occasionally causes tingling in the extremities, but this passes off rapidly.

598 Treatment of Malaria

H. WILLOUGHBY and E. ASLETT (*Journ. Royal Naval Med. Service*, April, 1931, p. 95) insist that the optimum maximum oral dosage of quinine in quartan infections is 10 grains three times daily, and the same quantity twice a day in subtertian cases; any excess is liable to induce toxic symptoms, especially in debilitated patients. The maximum effect on the parasites is obtained with these smaller doses, and the patient gains nothing by increasing them. Plasmoquine administration should be associated with glucose, thus decreasing the tendency to toxic symptoms, and for the first two courses the patient should remain in bed. The appearance of cyanosis should be taken as an indication to decrease the dose, but it should be remembered that patients who develop this sign are nearly always completely cured eventually. The plasmoquine compound with quinine is not recommended in cardiac disease, but it has a special value in cases resistant to quinine alone, when blackwater fever is indicated or present, in pregnant or puerperal women, and in children. The authors doubt whether salvarsan has any specific action on the malaria parasite. At the start of blackwater fever the threatened haemoglobinuria may be averted by rapid alkalinization of the urine, gradual desensitization with the plasmoquine compound, and the treatment of constipation by calomel in one or two doses, and not by the repeated subminimal dosing which causes acute colic. The authors favour the intravenous administration of 150 grains of sodium bicarbonate in one pint of 5 per cent. glucose solution, when acidosis has to be prevented or the blood pressure raised. They doubt whether there is any risk of the formation of carbonates in the blood stream by this method, but give details of the special precautions which should be observed. Caffeine citrate has a useful diuretic effect when suppression of urine is threatened. Blood transfusion is not advisable during the haemoglobinuric process, but is of value subsequently.

599 Intraspinal Magnesium Sulphate for Intolerable Pain

A. GORDON (*Med. Journ. and Record*, April 15th, 1931, p. 399) advocates intraspinal injections of magnesium sulphate for the relief of intolerable pain, and records satisfactory results in twelve cases (four of tabes, seven of radiculitis, and one of fibroblastoma of the cord). Based upon sound physiological deductions and experimentation, it is claimed that in certain cases of root pain, due to organic involvement of the central nervous system, relief can be obtained and existence rendered tolerable thereby. Success depends largely upon wise discrimination as to dosage, frequency, and length of intervals in treatment. The minimum adult dose is 2 c.cm. of a 25 per cent. solution of magnesium sulphate, but in long-standing cases, when the patients are exhausted by pain and want of sleep, 4 c.cm. may be given. The spinal puncture should be below the second lumbar vertebra, preferably between the third and fourth or the fourth and fifth vertebrae. Immediately following the withdrawal of 5 c.cm. of spinal fluid, the solution should be introduced while the needle is in position; the patient is kept quiet in bed for several hours in a lateral position. Even in cases where a dry tap results, owing to blocking of the subarachnoid space, the injection should still be made. In one of the author's cases considerable relief was obtained though several dry punctures were made. In all the cases prior to the trial of the intraspinal method sedatives had failed to give any relief. One tabetic patient was completely relieved of severe lumbar pain and girdle sensation after three 2 c.cm. injections at weekly intervals, and the pain in the legs became better. There was also noticeable improvement in gait, ataxia, and bladder control.

600 The Administration of Salicylates

G. H. W. LUCAS and V. E. HENDERSON (*Canadian Med. Assoc. Journ.*, April, 1931, p. 541) suggest a way of giving large and repeated doses of the salicylates without causing gastric irritation. The acidity which is induced by these salts has been attributed to the liberation in the stomach of salicylic acid, and attempts have been made to neutralize it by administering simultaneously sodium bicarbonate: Since a mixture of sodium bicarbonate and salicylate has an unpleasant taste, it has usually been prescribed in capsule form, or in powder rapidly washed down by a little water; the salts are liberated from the capsule in the stomach in a concentrated form, and the tendency to gastric irritation is thus accentuated. The authors therefore prefer to employ calcium carbonate or magnesia with salicylates in solution; the consequent colour changes in the fluid are prevented by small doses

of sodium thiosulphate. The mixture is made more palatable by the addition of the compound syrup of sarsaparilla (*United States Pharmacopoeia*), or of syrup and aqua menthae piperitae.

601 Bismuth Arsphenamine in Early Syphilis

J. H. STOKES, T. H. MILLER, and H. BEERMAN (*Arch. Derm. and Syph.*, April, 1931, p. 624) report their conclusions derived from several years of exhibiting in various forms of syphilis an arsphenamine synthetic of bismuth known as bismarsen. This preparation has an arsenical content of 12 to 15 per cent., and 23 to 25 per cent. of bismuth. It is injected intramuscularly in doses of 0.1 to 0.2 gram in adult patients at intervals of once in two to once in seven days; the drug is dissolved in water containing butyn, which acts as a local anaesthetic. Courses range from eight injections in a series to as many as forty; toxicity is low, but the individual degrees of reactivity vary. In 2 per cent. of the authors' cases there was local stiffness with slight pain, yielding to massage and hot applications. In 11 per cent. of patients there were mild systemic reactions in the form of nitritoid crises, gastro-intestinal disturbances, and cutaneous symptoms. Three cases of jaundice have been reported so far, but there have been no cerebral manifestations. In early syphilis two injections a week are advised; the effect on the Wassermann reaction is excellent and lasting, and the proportion of relapse was 12 per cent., as compared with 20 to 40 per cent. in a carefully studied series of cases treated otherwise. The authors obtained evidence that intermittent administration was less effective than continuous treatment; marked tonic effects were usual. Fair results followed the use of bismarsen in cardio-vascular syphilis, and there appeared to be no need to associate it with iodides and mercury. Little or no alteration occurred in the paretic formula of the cerebro-spinal fluid, and it was concluded that the most favourable field for bismarsen was that of early syphilis.

Anaesthetics

602 Fatal Colitis Caused by Avertin

I. WYMER (*Schmerz Narkose-Anaesthesie*, April, 1931, p. 19) records the case of a man who was anaesthetized with avertin introduced into the rectum for the removal of a vesical calculus; 0.16 gram of avertin for each kilo of body weight was given in a 2 per cent. solution. The patient was restless during the operation, and ether had to be administered. After the operation the rectum was washed out with saline solution, but the patient never recovered consciousness, and died in forty-eight hours. At the post-mortem examination a severe necrosing phlegmonous inflammation of the ascending colon was found. Discussing the case, the author states that mucus and blood in the stools, indicating the presence of colitis, is not uncommon after avertin. There was no question in this case of chemical changes having taken place through overheating, but it is possible that the avertin was injected too far; having reached the ascending colon its action was prolonged owing to its being uninfluenced by the saline lavage. The dose was also larger than that used in most clinics. To indicate further the toxic effects of avertin, Wymer also produced necrosis of the skin and subcutaneous tissues in animals by hypodermic injection.

603 Neocaine as a Spinal Anaesthetic

E. E. ARNHEIM and S. MAGE (*Annals of Surgery*, April, 1931, p. 929) record a series of 497 cases in which spinal anaesthesia was employed, usually a single dose of 120 mg. of neocaine in crystalline form dissolved in the spinal fluid, and comment on the importance of selecting suitable cases—namely, those in which a general anaesthetic is contraindicated, or those in which the operative procedure, usually abdominal, is of some magnitude. In most cases the surgeon acted as anaesthetist; the lumbar puncture was performed with the patient sitting up, or in the lateral position, this being altered immediately afterwards to a slight Trendelenburg posture. Morphine and atropine were administered before the injection in 345 cases, codeine and atropine in 13, and ephedrine in 145. The usual dose of ephedrine was 50 mg. In 8 cases (1.6 per cent.) no anaesthesia ensued, and in 163 (32.8 per cent.) general anaesthesia had to be induced. The authors remark that they have found that the need for such supplementary anaesthesia is reduced by using larger doses of the neocaine. The occurrence of shock on the operating table was usually confined to patients of advanced age and with arterio-sclerosis and myocardial disease, or to cases of cachexia or of intoxication resulting from some debilitating disease. Patients with hypertension may develop suppression of urine as a result of untreated fall in the blood pressure. There was a relatively high incidence of post-operative pneumonia (21 cases, or 4.2 per cent.). There was one toxic anaesthetic death, the other two deaths being due to errors in technique which are considered to be avoidable.

604 Ether Hyperglycaemia

Hyperglycaemia during and following ether anaesthesia is a striking manifestation of the effect of that drug on carbohydrate metabolism. A. CANTAROW and A. M. GEHRET (*Journ. Amer. Med. Assoc.*, March 21st, 1931, p. 939) discuss this condition with especial reference to hepatic disease, and record a series of observations made at intervals during operations under ether on 8 patients with biliary tract disease and 4 with other conditions. Two theories have been advanced to explain this hyperglycaemia. One, not generally accepted, is that it is due to depression of the pancreatic internal secretory function (hypo-insulinism); the other, which the present authors approve, ascribe it to increased hepatic glycogenolysis, due either to the direct action of the anaesthetic or to the increased hydrogen-ion concentration associated with ether anaesthesia. Before their operations all the present patients received a diet high in carbohydrates with supplementary dextrose therapy. The average rise in blood sugar for each ounce of ether administered was 2.9 mg. per 100 c.cm. in patients with frank icterus, as compared with 7.6 mg. in those with biliary tract disease without jaundice. All the patients made good recoveries with the exception of one who, receiving 14 ounces of ether, failed to show any appreciable rise in the blood sugar content, and died 18 hours after the operation. The necropsy revealed extensive acute necrosis of the liver, which was not present at the operation. Pre-operative liver function tests had not differed from those in the other jaundiced patients. The authors conclude that all patients with biliary tract disease should be regarded as having hepatic damage, whether or not hepatic insufficiency is demonstrable.

Obstetrics and Gynaecology

605 Treatment of Placenta Praevia

P. A. MCLEOD (*Canadian Med. Assoc. Journ.*, April, 1931, p. 508) emphasizes the importance of losing no chance of prophylactic treatment when the existence of placenta praevia is suspected. Should slight bleeding occur during the last few months of pregnancy, unaccompanied by pain, it is unwise to make a digital examination to confirm the probable diagnosis until preparations have been completed for dealing effectively with the consequent intensification of the haemorrhage, since it is easy to dislodge a blood clot or open up a new sinus. Such an examination should be conducted, therefore, in a fully equipped delivery room, with bags and sterile solution ready; if possible, blood transfusion facilities should be available. Shock should be anticipated, by transfusion if serious bleeding has occurred, even though there are as yet no serious symptoms. As an emergency measure, the intravenous injection of a 6 per cent. solution of gum acacia and 20 per cent. glucose will sustain the blood pressure longer, and the fluid will be absorbed more slowly, than

if the gum is omitted. From 400 to 1,000 c.cm. of this solution at a temperature of 105° is administered at a rate of 4 to 6 c.cm. a minute. In the management of the more severe marginal type of placenta praevia, and of the less severe partial form, McLeod prefers to introduce the Voorhees bag; this, being cone-shaped and filled with fluid, forms a true hydrostatic wedge, fits the cervix, accomplishes a fairly rapid dilatation, and acts simultaneously as a tampon to control the bleeding. He finds that its insertion in the cervix beneath the placenta is usually quite satisfactory, but the fluid should be injected slowly so as not to stretch the lower uterine segment too rapidly. The subsequent delivery should be brought about by version and extraction, it being remembered that slow extraction will complete the dilatation of the cervix, and will leave it so open as not to obstruct the after-coming head. Hasty extraction may tear a soft and friable cervix to which the placenta has been attached, and the resulting haemorrhage from ruptured sinuses may be serious. Details are given of the treatment recommended at the different stages, and the author discusses the indications for Caesarean section.

606 Carcinoma of the Vagina

E. LÖVEGREN (*Acta Paediatrica*, March 15th, 1931, p. 371) records a case of primary carcinoma of the vagina which proved fatal at the age of 1 year and 10 months, six months after the onset. The symptoms were blood in the urine, haemorrhage apart from micturition, debility, and anaemia. Curetting and radium treatment caused a temporary improvement in the general condition. During the last two months, however, a rapid loss of nutrition set in, and metastases appeared in the lower part of the abdomen. There was no necropsy, but histological examination of scrapings of the tumours showed that it was a papillary epithelioma. Lövegren has found only one other case of carcinoma of the vagina in an infant, which was described by Aschheim in a child, aged 6 months, who had an adenocarcinoma on the anterior vaginal wall, with the ovaries converted into cystic tumours. In contrast with carcinoma, sarcoma of the vagina is not so rare in children, since there are about two dozen cases on record.

607 I. DE BÜBEN (*Surg., Gynecol. and Obstet.*, April, 1931, p. 884) states that vaginal carcinoma is the most malignant, the most difficult to cure, and the most dangerous variety of cancers of the female genitalia. The patients are usually past the climacteric, and little is known as to the etiology. The growth is situated as a rule in the upper third of the posterior vaginal wall, the place most exposed to trauma. Histologically the neoplasm presents the appearance of a squamous-celled cancer or, exceptionally, of an adenocarcinoma. The results obtained by operation or radiotherapy (irradiation of the growth locally with radium and of the infiltrated lymphatic glands with *x* rays) are far from satisfactory. Radiotherapy has a wider range of applicability than surgery, and in most cases has only a temporary palliative effect. The Wertheim method, or total extirpation, combined with resection of the rectum in cases with the growth in the posterior vaginal wall, is considered to result in recovery more often than other procedures.

608 Uterine Hypertony in Successive Labours

P. BALARD (*Bull. Soc. d'Obstét. et de Gynécol. de Paris*, March, 1931, p. 181) reports two cases, in each of which extreme uterine contraction occurred in two successive labours. Uterine hypertony, except in primiparae, is relatively rare, and such a repetition as is recorded by Balard is most exceptional. Both patients were 2-paras. In the first, both labours were associated with premature rupture of the membranes, the breech presenting on the first occasion, and the head on the second. In the second case, the first labour only was associated with premature rupture of the membranes, and both presentations were of the usual cephalic type. In both cases there was no hydramnios, and the pelvis was normal. Amniotic infection was present in both patients; in the first one, this occurred before the contraction in both labours; in the second patient, the contraction developed well before the infection in the first labour, and in the second the embryo was intact and pyrexia was absent. Besides the factors usually considered as the causes of uterine hypertony, Balard suggests that this condition may be due to a peculiar irritability of the uterine fibres. Low Caesarean section is recommended in such cases provided that the clinical signs show that the infant will not suffer thereby; it was performed in both of Balard's cases.

609 Cancer of the Cervix after Subtotal Hysterectomy

According to R. MONOD (*La Gynécol.*, February, 1931, p. 106) 138 cases of cancer in the cervical remnant after subtotal hysterectomy were treated in anticancer clinics in Paris during the past ten years; the condition is less rare than has been reported. Some of the intracervical cancers which are detected within a few months or years after hysterectomy were present before the operation; some of the growths, usually of squamous-cell type, found many years after operation, may be regarded as provoked by it. Cancer of the cervical stump occurs most frequently after an operation for fibroma, and Polak among nine hundred fibromata found in 2 per cent. a cervical cancer which a subtotal operation would have permitted to evolve. Monod advises that the subtotal kind should be abandoned in favour of total hysterectomy. After the former operation has been performed in exceptional cases, it is advisable to open and examine the operation specimen before the abdomen is closed, and to examine the patient periodically after her apparent cure. Surgical treatment of cervical carcinoma is unusually difficult after hysterectomy; as a rule radium therapy is preferable, but the prognosis is bad.

610 Foetal Ascites

N. GUPTA and P. CHANDRA DAS (*Indian Med. Gazette*, April, 1931, p. 186) record two cases of foetal ascites in view of the rarity and clinical importance of this condition. They remark that it is found most commonly in the form of a general foetal dropsy, associated with hydrothorax, and sometimes with maternal dropsy. Nearly all the cases are premature, mostly between seven and eight months, and dystocia from this cause is infrequent; when it does occur the true nature of the obstacle is likely to be overlooked. Dystocia was absent in both cases recorded by the present authors. The labour is generally premature and the presentation vertex; uterine pains are usually weak from over-distension of the maternal abdomen. Though difficulty is encountered in the delivery of the child, owing to its abdominal distension, yet the foetuses are often born spontaneously owing to their prematurity and compressibility. Rupture of the uterus is extremely rare. In the two cases recorded there were no malformations of the urinary apparatus, congenital syphilis, or portal obstruction. There was some evidence of an inflammatory process of the peritoneum in both cases, but its cause was obscure.

Pathology

611 Experimental Transmission of the Common Cold

P. H. LONG, J. A. DOULL, JANET M. BOURN, and EMILY MCCOMB (*Journ. Exper. Med.*, April, 1931, p. 447) have succeeded in transmitting the common cold to human volunteers by nasal instillation of bacteria-free filtrates of nasopharyngeal washings obtained from persons suffering from natural infection. The experiments, which were made on healthy young women, were carried out during the months of June and July, when there was a low incidence of respiratory infection among the normal population. The volunteers were kept in strict quarantine, and were observed for from two to six days before inoculation. During this time they received nasal instillations of filtered yeast infusion broth in order to prevent them from knowing the time of inoculation. The actual inoculations with infective material were made by instilling 0.5 to 1 c.cm. of a Seitz or Berkefeld W filtrate into each nostril,

the subject being in the supine position with the head tipped back; the mucous membranes of the anterior nares and the posterior pharyngeal wall were then lightly rubbed with swabs soaked in the filtrate. Each subject received from one to three inoculations within a period of twenty-four hours. The filtrates were found to be free not only from the ordinary bacteria, but also from the tiny Gram-negative anaerobic organisms which can pass through a Berkefeld V candle. Altogether 20 inoculations were made from nine subjects with natural colds into nineteen volunteers; eleven of these inoculations were successful in setting up colds. Serial passages through two and four volunteers were successfully accomplished. The incubation period was 20 to 70 hours; no cold developed after three days. The authors conclude that the common cold is due to infection with a filterable virus.

612 Sugar Tolerance in Infants

T. G. H. DRAKE and C. E. SNELLING (*Canadian Med. Assoc. Journ.*, April, 1931, p. 511) from their investigations upon sugar tolerance curves in acute intestinal intoxications in infants confirm the findings of Tisdall, Drake, and Brown, who showed that in such cases the ability to utilize glucose injected into the blood stream is lessened, since it disappeared less rapidly than in the case of normal infants, the rate of removal being inversely proportional to the degree of toxaemia. The present report shows an absolute correlation between the intensity of the intoxication and the increase in height and width of the sugar tolerance curve. In the investigation 10 c.cm. per pound of body weight of a 10 per cent. glucose solution was injected into the superior longitudinal sinus; blood sugar determinations by Folin's method were made before the injection, and half an hour, one hour, two hours, and three hours afterwards. This was repeated every second or third day. In normal infants the average blood sugar is 0.09 mg. per 100 c.cm.; half an hour after an injection of this amount of glucose solution it rises to 0.285 mg. per 100 c.cm., returning to the 0.09 mg. level one hour later. In cases of acute intestinal intoxication the blood sugar rose to 0.375 mg. in half an hour, and did not return to the 0.09 mg. level until three hours had elapsed.

613 Jaundice and Iron Metabolism

T. BRÜGSCH (*Med. Klin.*, April 10th, 1931, p. 536) has shown that after the daily oral administration of large doses of reduced iron, the iron content of the urine is not significantly increased. Applying the test to a series of cases of jaundice, he demonstrated that in icterus due to hepatic toxaemia, in mechanical jaundice, and in biliary cirrhosis the iron content of the urine is never significantly raised above the limit of health. In hepatic disease accompanied by jaundice the formation of bilirubin and iron from the colouring matter of the blood occurs in the liver; the bilirubin passes out into the tissue fluids and causes the icteric colouring, the iron remaining for the most part in the liver. The deposit of iron in the liver in jaundice does not lead to its increased excretion in the urine or in the bile. Whether the iron in the liver is, during convalescence, gradually excreted by the bowel, or is retained in the body to be used in the reconstruction of haemoglobin, is not known. Although the liver is the chief originating source of jaundice, it is also probable that it may arise in the skin. It is pointed out that the [illegible] subcutation evoked by the intradermal injection of [illegible] injection. [illegible]ricyanide is not a certain indication of severe [illegible]ith jaundice, since the effect may be pro-

603 Neocain[illegible]dation of excess of bilirubin in the skin.

E. E. ARNHEIM and [illegible] 1931, p. 929) record a **Estimation of Living and Dead** anaesthesia was emp**ercle Bacilli in Sputum** 120 mg. of neocaine [illegible] (*Zeit. f. Tuberkulose*, April, 1931, spinal fluid, and comr[illegible] method for ascertaining the number suitable cases—namely[illegible]d tubercle bacilli in sputum. The thetic is contraindicate[illegible] 1 to 2 grams are weighed out, 4 per procedure, usually abdo[illegible]dium hydrate is added, and the most cases the surgeon ac[illegible]with a glass rod till it is rendered puncture was performed w[illegible]henolphthalein as an indicator, the alkali is neutralized with normal hydrochloric acid; the resulting neutral digested sputum serves as the material from which dilutions for counting are made. The total number of tubercle bacilli is determined by mixing the suspension with yeast cells, making and staining a film, and determining the number of bacilli and yeast cells in 25 to 50 fields. The yeast suspension is counted in an ordinary Thoma-Zeiss chamber. Knowing the relation of bacilli to yeast cells, and knowing the number of yeast cells per c.cm., it is easy to calculate the total number of bacilli per cubic centimetre of homogenized sputum. The count of living tubercle bacilli is made by streaking a normal loopful of the original suspension and of varying dilutions on to tubes of Lubenau's egg medium, incubating for three to four weeks, and counting the number of colonies which have developed. As an illustration of this method, the author quotes an instance in which there were 37 million tubercle bacilli per c.cm., of which 29 per cent. were alive and 71 per cent. dead.

615 Gall-bladder Disease and Carbohydrate Metabolism

The relatively frequent occurrence of gall-bladder disease in diabetic patients suggests that diabetes may often be a secondary condition, the primary disturbance being in the gall-bladder. Investigation of a series of cases of cholelithiasis and cholecystitis has convinced H. STRAUSS (*Dtsch. med. Woch.*, March 27th, 1931, p. 530), however, that both hyperglycaemia and alimentary glycosuria are of relatively rare occurrence in these diseases, and that while disturbances of the external secretion of the pancreas are fairly common, there is probably no direct relation between cholecystitis and disorders of carbohydrate metabolism. The frequency with which diabetes is found to have followed infective disease of one kind or another indicates rather that cholecystitis predisposes to diabetes merely by virtue of its infective nature.

616 Apparent Specificity among Streptococci

J. C. WALKER (*Journ. Lab. and Clin. Med.*, March, 1931, p. 539) states that there is a variation from year to year among the varieties of streptococci present in the sputum of asthmatic patients, of patients with uncomplicated chest colds, and of those with chest colds complicated by asthma; there is, moreover, variability in the prevalence of the same streptococcus in the same year in the case of the three conditions named. A mixed vaccine comprising the more prevalent varieties of streptococci for a given period has considerable value, both as a preventive and as a curative in chest colds and asthma. Failure of this vaccine in some cases was due to the presence of an insufficient quantity of the particular causative streptococcus, and relief followed the administration of an autogenous vaccine in which larger amounts of the causative microbe were present than in the mixed. In other cases failure of the mixed vaccine was due to the fact that the illness was caused by one or more of the less prevalent strains of streptococci being absent from the vaccine. The results of treatment in 89 patients, here presented, contraindicate any non-specific effect of vaccines, and support their specificity. In many cases vaccine treatment was undoubtedly specific, and showed a specificity among the common streptococci.

617 The Basal Metabolism in Pulmonary Tuberculosis

S. P. VELOSO (*La Med. Ibera*, March 28th, 1931, p. 461), who records 24 cases in patients aged from 19 to 62, illustrating the behaviour of the basal metabolism in pulmonary tuberculosis, comes to the following conclusions. (1) The basal metabolic rate varies even on the same day and in the same subject. (2) The basal metabolic rate is closely related to the severity of the infective process; a careful study of the rate will throw light on the course of the disease. (3) A rise in the basal metabolism may be due to activity of the tuberculous process. (4) A gradual or sudden rise is an unfavourable prognostic, while a fall is a favourable sign. (5) Examination of the basal metabolism is therefore a valuable guide to prognosis and treatment in pulmonary tuberculosis.

An Efficient Oral Antiseptic Need Not be Disagreeable to the Taste

Too often the use of an oral antiseptic is associated in the patient's mind with a disagreeable taste. That such an antiseptic need lack nothing in efficacy, whilst being pleasant in taste, is most forcibly proved in the instance of Odol Mouthwash.

Experiments and the experiences of medical men in the past with Odol have proved it to be a most efficient bactericide. In addition, it is absolutely harmless and cannot in any way injure the most delicate mucous membrane of the mouth.

In prescribing Odol Mouthwash doctors will obtain the desired results in a way most pleasant to the patient.

Odol

At GAMAGES

THIS HIGH-GRADE CHAUFFEUR'S SUIT COSTS ONLY 70/-

The appreciable difference in the price of Gamages high-grade liveries is due to the enormous buying resources of this great organisation. Gamages secure advantageous discounts on the bulk purchase of cloths, the market prices of which are already the lowest for seventeen years. The combination of these favourable circumstances enable Gamages to offer quality Liveries at the lowest prices in town.

THE SUIT COMPRISES Double-breasted Jacket, Vest and Trousers made from a good weight Navy Blue Ribbed Serge. This suit combines neatness with style, and can be purchased Ready for Service.
PRICE 70/-, better qualities 90/-, 110/-.

CHAUFFEURS' DUST COATS

Made from Alpaca specially selected for its hard-wearing qualities. These are very smart in appearance yet exceptionally light in weight. Stocked in all usual sizes in blue or grey. PRICES **25/6** and 35/-

POST ORDERS.—State height and chest measurement taken loosely over waistcoat.

Post Orders. The Gamage simplified self-measurement chart has been compiled from years of experience, and will be sent free with patterns on request. Alternatively, customer may prefer to send an old livery for pattern, in which case we pay postage one way.

FOR INTERNAL TREATMENT OF GONORRHOEA, URETHRITIS, AND OTHER AFFECTIONS OF THE GENITO-URINARY TRACT

SANTAL MIDY CAPSULES have been prescribed with uniform success for over thirty years. Distilled from carefully selected Mysore Sandal Wood, the oil is bland and remarkably

FREE FROM THE IRRITANT AND NAUSEATING EFFECTS

which are provoked by many preparations.
There is marked absence of gastric and other disturbances, diarrhoea and skin eruptions. Its mild chemotactic properties permits its administration in relatively large doses without fear of too violent reaction or tolerance.

SANTAL MIDY CAPSULES may be prescribed and relied upon in all stages of Gonorrhoea and in other forms of Urethritis and affections of the Genito-Urinary tract.
The Capsules contain 5 drops, and usually 10 to 12 are given daily in divided doses.

Prepared in the Laboratoire de Pharmacologie Générale, 8, Rue Virienne, Paris, and sold by most Chemists and Wholesale Druggists throughout the World.
U.K. Agents: WILCOX, JOZEAU & Co., 15, Gt. St. Andrew St., W.C.2

FOR DEAFNESS

Doctors prefer "ARDENTE" because—

"ARDENTE" STETHOSCOPE.
Mr. R. H. Dent makes a Stethoscope specially for members of the medical profession suffering from deafness. Many are in use, and excellent results are reported on the latest, as evidenced by the interest shown at the last B.M.A. Meeting

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, thus relieving head noises, giving inconspicuous hearing.
4. It conveys sounds from varying ranges and angles.
5. It is entirely different, uncopyable, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf through various causes.
7. It is helpful for conversation, music, talkies, wireless, home, office, public work, and sports.

FREE HOME TESTS
arranged for Doctors and Patients.
Medical Prescriptions made up to the minutest detail.

MEDICAL REPORTS.
Commended by all leading medical journals.—Mr. Dent will be happy to send full particulars and reprints on request.

THE 'ALLENBURYS' CASTOR OIL
Is Tasteless and is the Standard of Quality
Supplied in bottles at 8d., 1/3, 2/3 and 4/- each

BANTAM Coffee

Bantam Coffee is prepared from the finest selected Empire grown beans which are powdered and all the waste grounds extracted so that it dissolves instantly and completely when hot water or milk is added. A little Bantam Coffee dropped in a glass of warm milk makes a very palatable beverage. Bantam Coffee is absolutely free from adulterants and has been awarded the certificate of the Institute of Hygiene.
A 2/- tin yields 50 cups of delicious coffee.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or who wish to prevent recurrent attacks of mental trouble; temporary patients; and certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

HAYDOCK LODGE,
NEWTON-LE-WILLOWS, LANCASHIRE.

'Phone: 11 Ashton-in Makerfield.

For the reception and treatment of PRIVATE PATIENTS of both sexes of the UPPER AND MIDDLE CLASSES either voluntarily or under Certificate. Patients are classified in separate buildings according to their mental condition.

Situated in park and grounds of 400 acres. Self-supported by its own farm and gardens, in which patients are encouraged to occupy themselves. Every facility for indoor and outdoor recreation. For terms, prospectus, etc., apply MEDICAL SUPERINTENDENT.

COURT HALL, KENTON, EXETER,

The Hospital is equipped for the diagnosis and treatment of any form of ill-health, except Mental and Infectious Diseases. The fees are inclusive.

The climate is mild and the neighbourhood beautiful. Apply: The Secretary,

Telegrams: Castle Ruthin. Telephone: 66, Ruthin. Ruthin Castle, North Wales.

BETHLEM ROYAL HOSPITAL, for Nervous and Mental Disorders,

Monks Orchard, Monks Orchard Road, Eden Park, Beckenham, Kent.

Reg. Tel. Address: Bethlem, Beckenham. *Telephone:* Springpark 1180—1181.
Station: Eden Park (Southern Railway).

President: LORD WAKEFIELD OF HYTHE, C.B.E., LL.D.
Treasurer: SIR LIONEL FAUDEL-PHILLIPS, Bart.
Physician-Supt.: J. G. PORTER-PHILLIPS, M.D., F.R.C.P.

This Registered Hospital is now situated at Monks Orchard, in some 250 acres of park, pleasure, and farm grounds.
Applications can be considered on behalf of patients of the educated classes in a presumably curable condition.
With a view to early treatment voluntary or uncertified patients are admitted.
Patients who can contribute 5 guineas weekly towards the cost of treatment and maintenance may be received as vacancies arise. The Committee will also consider applications for admission at lower rates, and in certain cases will be prepared to admit patients free of charge.
Every facility for specialized investigation and treatment is provided in the Lord Wakefield Science and Treatment Unit. In this Unit is found the X-ray and Dental Departments and the Bio-Chemical, Pathological, and Psychological Laboratories.
Furthermore, provision is made for Electro-Therapy and Hydro-Therapy to be carried out in all their forms.
In addition to the Resident Medical Staff, Consultants in special branches of Medicine and Surgery are available whenever required.
The comfort of sensitive patients is greatly enhanced by the fact that the majority are given single bedrooms.
For forms and further particulars apply to the Physician-Superintendent at the Hospital.

INDICATIONS: Asthma, emphysema, bronchitis, diseases of the throat, nose, and larynx, heart trouble, diseases of metabolism. Largest installation in the world for pneumatic chambers and inhalation. Beautiful mountain scenery. Strongest saline springs on the Continent. Potable Springs. All modern comfort. All kinds of sports and entertainments. Open all the year round. Information regarding hotel and travel facilities will be gladly given by Thos. Cook & Son, and the "Kurverein Bad Reichenhall" direct.

BAD BRUECKENAU

The Spa for Kidney Trouble—Wernarzer Curative Spring. Highly successful in cases of uric acid diathesis, for gout, kidney, stone, gravel and bladder troubles. Chalybeate spring proved successful for anaemia, women's diseases and diseases of the nerves. Chalybeate and mud baths known to the medical profession for centuries. Hunting and fishing. Spa opens May 1st. Twelve "Kur Halls," Railway Line Hamburg—Munich, local railway from Jossa, also via Bad Kissingen. Fulda and Schlüchtern can be reached by State Route Motor Cars. Information and Prospectus from the "Staatl. Bayerischen Mineralbades Brückenau in Unterfranken."

BAD STEBEN (Therapeutic)

The Chalybeate and Mud Bath in the Frankenwald, 1,906 ft. above sea-level. Proved in cases of anaemia, chlorosis, heart, nerve and women's diseases, gout, rheumatism, sciatica; bathing, drinking and air cures. Park, rest hall, forest environment. Information from the "Staatl. Badeverwaltung" and Travel Bureaux.

Exceptional curative successes. **Best installed Spas.**

VICHY FRANCE

The waters of Vichy belong to the sodium bicarbonate group. They are generally gaseous, clear, and colourless. They are nearly all similar in composition and contain, approximately, a total of 7.5 grammes of mineral matter which includes, notably, bicarbonates of sodium, potassium, calcium chloride and sulphate of sodium, free carbonic acid, and those rare gases: argon, krypton, xenon, helium, neon, etc. At their source, the springs present differences in temperature which give a variety of physiological actions due to their peculiar vitality.

The Thermal Establishment is justly considered as a model of its kind, and every care is taken that the latest discoveries in physiotherapy may be utilised under the best possible conditions for allowing the specific action of the waters to give the most beneficial results.

The cost of a stay at Vichy is surprisingly moderate. Hotels are numerous and comfortable and range from the most luxurious to the modest pension.

Detailed information concerning the treatment at Vichy may be had by addressing the Compagnie Fermière de Vichy, 24, Boulevard des Capucines, Paris.

LUCERNE *The PEARL of Switzerland.*

Fine Lido-Beach. Golf and all Sports. Rest and Recreation.

UNIVERSITY OF LONDON.

EXTERNAL EXAMINERSHIPS, 1932.

The Senate announce the following vacant Examinerships for the year 1932:

For the First Examination for Medical Degrees.
GENERAL BIOLOGY. PHYSICS.

For the Second Examination for Medical Degrees.
PHYSIOLOGY (Two).

For Final and Higher Examinations for Medical Degrees.
FORENSIC MEDICINE AND HYGIENE (Two).
MENTAL DISEASES AND PSYCHOLOGY.
NEUROLOGY. PATHOLOGY.
TROPICAL MEDICINE.

Associate Examiners.

Applications will also be invited for Associate Examiners in Medicine, Obstetric Medicine, Pathology, and Surgery. A separate application form must be used for Associate Examinerships and the word "Associate" must be written on it.

Application form (or forms if more than one Examinership is applied for) and particulars of the remuneration and duties can be obtained from the External Registrar.

Candidates must send in their names to the External Registrar, GEO. F. GOODCHILD, M.A., B.Sc., with any attestation of their qualifications they may think desirable, on or before Monday, July 6th, 1931. (Envelopes should be marked "Examinership.")

The Senate desire that no application of any kind be made to individual members.

If testimonials are submitted one copy only of each is required. In no case should original testimonials be submitted. If more than one Examinership is applied for a separate and complete application must be forwarded in respect of each Examinership. The appointments will be made by the Senate in November. Applicants who desire that the result should be communicated to them are requested to enclose a stamped and addressed envelope with their applications.

Brougham Terrace, Liverpool. WALTER MOON, Town Clerk.

June 15th, 1931.

INDIAN MEDICAL SERVICE

Recruitment of European Officers.

Applications are invited from medical men for permanent commissions in H.M.'s Indian Medical Service. The terms offered include a gratuity of £1,000 on retirement after six years' service, or £2,500 after 12 years' service, together with free return passages, for those who no longer desire to remain in the Service. In other respects the terms will be as detailed below.

Candidates must be British subjects under 32 years of age at the time of application, and must be registered under the Medical Acts in force in Great Britain and Northern Ireland.

CAREERS.

The Indian Medical Service offers wide opportunities of medical experience, including clinical, preventive, specialist, and research work. At the beginning of his career an officer is employed on the military side, which has medical charge of the Indian Army. Promotion is on a time scale up to the rank of Lieutenant-Colonel, and by selection to the ranks of Colonel and Major-General. An officer may apply after one year's Indian service to have his name registered for transfer to the civil side, from which appointments are made to Civil Surgeoncies, which are established at the principal civil centres to provide for the medical needs of civil officials and for general medical administrative purposes; to specialist (for example, public health and bacteriological) services; to research posts; and to professorships at the Medical Schools.

NOTE.—It is not possible to state at present what, if any, prospects of employment on the civil side will be open to Indian Medical Service Officers under the proposed new constitution for India.

PAY.

The monthly rates of pay for European officers in the Service who have a "non-Asiatic" domicile are as follows:

Rank.	Service in Rank.	Basic Pay.	Overseas Pay.	Years of Total Service.
1	2	3	4	5
		Rs.	Rs.	
			150	1st
Lieut.	—	500	150	2nd
			150	3rd
Capt.	(i) During first 3 years' service as Captain	650	150	4th
			£15	5th
			£15	6th
	(ii) With more than 3 and less than 6 yrs.' service as Captain	750	£25	7th
			£25	8th
			£25	9th

	(iii) After completion of 25 years' total service	1700		
	(iv) When selected for increased pay	1850		

EXTRAS.—In addition to the above rates various allowances are admissible for a large number of special appointments on both the military and the civil side which may be held by members of the Indian Medical Service. Special high rates of pay are also attached to the numerous administrative appointments open to officers in both branches of the Service.

ANTEDATES IN COMMISSION.

Any service rendered by an officer during the war as a medical or combatant officer, or in a position usually filled by an officer, may be counted as service for increments of pay, promotion retirement and retired pay, but not for gratuity.

One half of any service in the ranks during the war may be counted as service for retirement and retired pay only.

Candidates possessing certain higher medical qualifications may be granted an antedate of one year in their commissions. Past service in certain hospital appointments may also render candidates eligible for an antedate of one year. Persons holding or about to hold resident posts at recognized hospitals may be seconded in those posts for a period not exceeding one year. The maximum period of antedate, secondment, or antedate and secondment combined, admissible under this paragraph, is limited to one year.

OUTFIT ALLOWANCE.

Officers on appointment will receive an outfit allowance of £50.

PRIVATE PRACTICE.

With the exception of Administrative Officers, military or civil, and officers holding certain special appointments, officers are not debarred from taking private practice, so long as it does not interfere with their proper duties.

LEAVE.

Leave can be taken at reasonable intervals, and adequate rates of leave pay are provided. Extra leave (known as study leave), which may not exceed 12 months in all during an officer's service, may be granted to officers desirous of pursuing special courses of study of a post-graduate nature. During such leave, study allowance, at present fixed at the rate of 12s. a day in the United Kingdom, £1 a day on the Continent of Europe, and £1 10s. a day in the United States of America, is granted to an officer in addition to ordinary rates of leave pay.

PENSIONS.

The rates of pension are as follows:

	Per annum. £
After 17 years' service for pension ...	400
„ 18 „ „ „ ...	430
„ 19 „ „ „ ...	460
„ 20 „ „ „ ...	500
„ 21 „ „ „ ...	540
„ 22 „ „ „ ...	580
„ 23 „ „ „ ...	620
„ 24 „ „ „ ...	660
„ 25 „ „ „ ...	700
„ 26 „ „ „ ...	750
„ 27 „ „ „ ...	800

These rates are subject to alteration on account of a rise or fall in the cost of living as compared with the year 1919 to an extent not exceeding 20 per cent. in all, the revision being undertaken triennially. With effect from July 1st, 1930, a reduction of 5½ per cent. has been made on this account from the amounts shown.

There are additional pensions ranging from £65 to £350 per annum for officers who have held administrative appointments.

PASSAGES.

An officer on appointment is provided with free passage to India. The wives and families of officers who are married prior to the date of the officers' embarkation on first appointment will also be provided with free passage to India, subject to the payment of messing charges.

Officers and their families are also eligible for passage concessions under which they are granted a certain number of return passages home at Government expense during their service.

INSTRUCTION PRIOR TO EMBARKATION.

Officers are required to undergo courses of instruction at the Royal Army Medical College and at Aldershot, lasting approximately six months, prior to their embarkation for India on first appointment.

Full details regarding these appointments and forms of application may be obtained from the Under-Secretary of State for India, Military Department, India Office, London, S.W.1. The Selection Committee will meet at the India Office early in July next, and the selected candidates will be required to join a course of instruction early in August, prior to sailing for India early in 1932. Applications should be submitted as soon as possible.

County Borough of Brighton.

PUBLIC ASSISTANCE COMMITTEE.

POOR LAW INSTITUTION.

The Public Assistance Committee require the services of the following officers at the Poor Law Institution, viz.:

(a) MEDICAL OFFICER (WHOLE-TIME, RESIDENT). Candidates must be registered Medical Practitioners, and preference will be given to those who have held appointments of House Physician and House Surgeon in a General Hospital, and who have had experience in the administrative control of a General Hospital or a Poor Law Hospital. The Medical Officer of the Poor Law Institution is also the Medical Officer of the Warren Farm Poor Law Schools, situated about 2 miles from the Poor Law Institution. Salary £850 per annum, together with residential allowances valued for the purposes of the Poor Law Officers Superannuation Act, 1896, at £150 per annum. A residence (unfurnished) will be provided, but until such time as he is able to take up residence the officer appointed will be paid a monetary allowance at the rate of £150 per annum in lieu of residential allowances.

(b) SENIOR RESIDENT ASSISTANT MEDICAL OFFICER. Candidates must be single men and preference will be given to those holding a F.R.C.S. degree and who have held the appointment of House Surgeon in a General Hospital, as the appointment is primarily for Surgical work, although not entirely so. The appointment is for one year only, but the person appointed will be eligible for further appointment from year to year. Salary £400 per annum, together with residential allowances valued for the purposes of the Poor Law Officers Superannuation Act, 1896, at £150 per annum. Residential accommodation is provided.

(c) VISITING SURGICAL SPECIALIST. Candidates must be registered Medical Practitioners and Fellows of a Royal College of Surgeons. The gentleman appointed shall have his residence within the Parliamentary Borough of Brighton. The appointment is in the first instance for one year, but the person appointed will be eligible for re-appointment. Salary £325 per annum, the person appointed to preside at his own expense a duly qualified Surgeon to act as his deputy.

Unless the officers appointed are transferred officers under the Local Government Act, 1929, the Poor Law Officers Superannuation Act, 1896, will not apply. The Local Government and other Officers Superannuation Act, 1922, is not in force in the County Borough of Brighton.

Forms of application, conditions of appointment, and lists of duties may be obtained from the Public Assistance Officer, Public Assistance Offices, Prince's Street, Brighton, which forms, duly filled up in the candidate's own handwriting and accompanied by copies of testimonials and a description of the diplomas, certificates of degrees, licences, and other instruments held by the candidate, must be returned to the Public Assistance Officer by 12 noon on Wednesday, July 1st.

Canvassing the Committee, either personally or by letter, will be considered a disqualification for appointment.

The Council of the County Borough of Brighton has adopted the Memorandum of Agreement as to Salaries of Whole-time Public Health Medical Officers.

By Order,
JAS. H. ROTHWELL,
Town Clerk &
Clerk to the
Public Assistance
Committee.

Public Assistance Offices,
Prince's Street,
Brighton.
June 8th, 1931.

St. Paul's Hospital for Diseases (INCLUDING CANCER) OF THE GENITO-URINARY ORGANS AND SKIN,

Endell Street, Holborn, W.C.2.

Applications are invited for the undermentioned position:

HOUSE SURGEON (vacant August 1st) Candidates must be doubly qualified and registered. Salary at the rate of £150 per annum, with board and residence. The appointment is for a period of six months, on the termination of which the holder is eligible for the position of Resident Medical Officer, in which capacity he will have charge of the Surgical beds. During his appointment as House Surgeon the duties will involve work in the Surgical Wards and in the out-patient Department for Venereal Diseases.

Applications, with copies of recent testimonials to be sent on or before July 6th to the Chairman of the Medical Committee.

City of Norwich.

ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER.

Salary £500, rising to £700 per annum by annual increments of £25; any other fees obtained must be refunded to the Council.

The person appointed will be required to devote his whole time to the services of the Council, and must not engage in private practice either within or without the Council's time, and he must be prepared to undertake any Medical duties of the Department, including occasional duty and/or residence at the Isolation Hospital, and work under the School Medical Service and Maternity and Child Welfare and Tuberculosis Schemes. Candidates must possess a Diploma in Public Health. Age not to exceed 40.

The officer selected will be under the direction and supervision of the Medical Officer of Health, who is also the School Medical Officer. The place of residence of the person appointed must be approved. The appointment will be subject to the terms and conditions of the Local Government and Other Officers' Superannuation Act, 1922, and the successful candidate will be required to furnish a medical certificate of fitness.

Applications, stating age, qualifications, experience, and when at liberty, accompanied by copies of not more than three recent testimonials, must reach the undersigned on or before June 25th.

Canvassing, directly or indirectly, is prohibited and will disqualify.

V. E. SOOTHILL, M.O.H. & S.M.O.
Public Health Department,
68, St. Giles' Street, Norwich.

County Borough of Rotherham.

OAKWOOD HALL SANATORIUM (100 Beds).

Applications are invited from duly qualified Practitioners for the post of ASSISTANT MEDICAL OFFICER (male) at the above Sanatorium.

Salary £300 per annum, with board and laundry. Rooms will be provided outside the Sanatorium.

Candidates must be under 35 years of age, unmarried, and of British nationality. They must have held resident Hospital appointments (general) and experience in the diagnosis and treatment of Tuberculosis, while not essential, will be an additional qualification.

The additional qualification. The appointment will be a whole-time official, and while mostly concerned with Tuberculosis will be available for any departmental emergencies. The appointment is terminable by two months' notice on either side and is for one year.

Applications, stating name, age, qualifications, and experience, together with copies of not more than three recent testimonials, should be sent to the undersigned on or before Tuesday, June 23rd.

CHAS. L. DES FORGES,
Town Clerk.
Municipal Offices,
Howard Street,

APPOINTMENTS.—Contd.

Huntingdon County Hospital.

HOUSE SURGEON needed. Salary £120 per annum, and laundry. Testimonials, etc., to Dr. GROVE, County Hospital, Huntingdon

The Royal Hospital, WOLVERHAMPTON. (Incorporated under Charter.)

HOUSE SURGEON required. The Hospital contains 240 beds, includes the usual Special Departments, and is recognised by the various Examining Bodies for a part of the requisite attendance on Medical and Surgical Practice.

Candidates must be registered under the Medical Acts, and unmarried.

The appointment is for six months. Salary at the rate of £100 per annum. Board, furnished rooms, and laundry provided.

Applications, with copies of testimonials, to be forwarded immediately to the undersigned.

W. H. HARPER, Wolverhampton. House Governor.

June 16th, 1931.

Woolwich and District War MEMORIAL HOSPITAL, Shooters Hill, London, S.E.18. (GENERAL HOSPITAL—112 Beds.)

The Board of Management invites applications from suitably qualified male candidates for appointment as HOUSE PHYSICIAN, for a period of six months as from July 1st. An honorarium of £100 per annum will be paid in respect of this appointment, plus board, residence, and laundry.

Applications should be addressed to the undersigned, to reach him not later than first post on Monday, June 22nd, and full particulars of experience, previous appointments, etc., together with copies of not more than three recent testimonials.

EDWIN RADFORD, Secretary-Superintendent.

Royal Infirmary, Blackburn. (240 Beds—5 Residents.)

FOURTH HOUSE SURGEON (male) required at a salary of £150 per annum, rising to £250, with board, residence, laundry, etc. To commence duties early as possible.

Applications, with copies of testimonials, stating age, nationality, experience, etc., to be sent at once to the undersigned.

Royal Infirmary, NATHAN A. SMITH, Blackburn. Gen. Supt. & Secretary.

This Institution is recognised for the Surgical practice required for the F.R.C.S. Final Examination.

National Hospital for Diseases OF THE HEART, Westmorland Street, W.1.

The Committee of Management invite applications for the post of PATHOLOGIST. Applicants, who must be duly registered Medical Practitioners, will be required to commence duties on September 1st, and to attend for a minimum of two hours daily on five afternoons weekly—Mondays to Fridays. Salary £250 per annum. Applications, with copies of not more than three recent testimonials, to be sent to the undersigned, at the Hospital, not later than July 11th.

ROBERT G. E. WHITNEY, Secretary.

Royal Northern Infirmary, INVERNESS. (150 Beds.)

Wanted, Two HOUSE SURGEONS (male) to commence duties on August 1st. The appointments are for six months. Salaries are at the rate of £100 a year, with board, residence, and laundry.

Applications, stating age, qualifications, etc., with copies of recent testimonials, should be sent not later than July 15th to

20, Church Street, ROBERT GILBERT, Inverness. Hon. Secretary.

St. Thomas's Hospital.

VACANCY.

DEPARTMENT OF PSYCHOLOGICAL MEDICINE.

One of the two CHIEF ASSISTANTSHIPS is vacant. Applications from gentlemen with experience of Psychological Medicine should be forwarded, with full *academical records*, etc., to the Secretary and Clerk to the Governors, St. Thomas's Hospital, S.E.1, by June 30th.

St. Thomas's Hospital.

VACANCIES. SURGICAL REGISTRARS.

There are vacancies for Two Surgical Registrars. Applications, with full details of Academic career, to be addressed to Lt.-Col. A. P. B. IRWIN, D.S.O., M.A.Cantab., Secretary and Clerk to the Governors, on or before June 30th.

The Hospital for Sick Children, Great Ormond Street, London, W.C.1.

A PART-TIME JUNIOR CASUALTY OFFICER is required on July 9th, to assist in the Casualty Department, from 10 a.m. to 3 p.m. (Saturdays 10 a.m. to 1 p.m.), under the direction of the Casualty Officer.

The work of this officer includes a large number of Tonsillectomies and other minor operations.

Candidates must be registered Medical Practitioners, and have held a responsible Hospital appointment.

Gentlemen are invited to send in their applications, addressed to the Secretary, before 12 o'clock on Monday, June 29th, accompanied by copies of not more than three testimonials written specially for the purpose.

The appointment is made for six months, and is non-resident. Salary at the rate of £150 per annum, with luncheon.

All candidates must be in attendance to appear before the Joint Committee, if required, at their meeting on Wednesday, July 1st, at 5 p.m. precisely.

Forms of application and copies of the Rules may be obtained from the Secretary, at the Hospital.

By Order of the Board of Management,
JAMES McKAY, Secretary.

June, 1931.

Victoria Central Hospital, WALLASEY.

Applications are invited for the position of JUNIOR HOUSE SURGEON (male). Salary at the rate of £100 per annum, with board, residence, and laundry, with prospects of appointment to Senior House Surgeon in six months' time, at a salary of £150.

Candidates chosen would be appointed for six months.

Applications, with copies of testimonials, to be sent to the Secretary.

The Queen's Hospital for CHILDREN, Hackney Road, London, E.2.

Two ANAESTHETISTS required, each to attend on two half-days each week. Honorarium £25 per annum. Certain additional paid appointments are open to holders.

Applications, with testimonials, should be sent to the undersigned as soon as possible.

June 5th, 1931. CHARLES H. BESSELL, Secretary.
Tel.: Bishopsgate 6305 and 2837.

Hertford County Hospital.

Applications are invited for the post of HOUSE SURGEON (male). Salary £200 per annum, with board, residence, and laundry. The appointment is for six months in the first instance.

Applications, with copies of three recent testimonials, should be sent to the undersigned.

PERCY G. BROOKS, Secretary.

All communications to be addressed to Mr. A. V. STOREY, General Manager.

BOVRIL MEDICAL AGENCY, Ltd.

ALDINE HOUSE,

10-13, BEDFORD STREET, STRAND, LONDON, W.C.2.

Telegrams: BOVMEDICAL, WESTRAND-LONDON. Telephone: TEMPLE BAR 1616 (3 Lines).

Under the personal directorship of Dr. J. FIELD HALL and J. C. NEEDES

who have both had many years' experience as Medical Transfer Agents.

The commission chargeable in respect of any practice or partnership in Great Britain placed exclusively in the hands of this Agency has been fixed on an exceptionally favourable scale, the maximum chargeable on any transfer being fifty pounds (£50).

No charge is made to Principals for the introduction of Locum Tenens or Assistants.
Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges.

1. LINCS.—PLEASANT MARKET TOWN.—PARTNERSHIP.—A half share, with possible succession in two years' time. Average income for past three years £1,900, including appointments and panel producing £500. Advice and medicine 3/- upwards; visits from 5/-. Very few midwiferies from 2 to 3 guineas. Large house with garden and garage. Price freehold only £1,200. Sport of all kinds, and excellent schools for boys and girls. Premium 2 years' purchase, payable £1,000 down, remainder by arrangement.
2. PARTNERSHIP.—WITHIN 70 MILES OF LONDON.—A fourth share (to commence) of old-established rapidly increasing mixed-class Practice, situated in very pleasant country town. Cash receipts last year nearly £4,000, including appointment £200 and panel over 2,000. Good house available, by purchase or rental. Premium £2,000. Incomer should be experienced and about 30 years of age.
3. WITHIN 10 MILES WEST OF LONDON.—Well-established mixed-class Practice, situated in pleasant rapidly increasing and developing district, offering considerable scope and future prospects. Receipts £1,200, including panel of 900. Good modern house (6 bedrooms, etc.) with nice garden, etc. Price freehold £1,450, £1,100 on mortgage. Premium £1,800.
4. EASTERN COUNTIES.—PARTNERSHIP.—A one-third share, with increase later, is offered in a very good mixed-class Practice, situated in pleasant town near sea. Average gross cash receipts nearly £4,500, including panel of about 3,000. Visits 2/6 to 30/-, with medicine extra. Very nice house, in large garden, containing 3 reception, 5 bedrooms, etc. Price for freehold £2,000. Premium 2 years' pur.
5. FAVOURITE SOUTH COAST TOWN.—PARTNERSHIP.—A share representing about £750 a year (with increase later) is offered in a good mixed-class non-dispensing Practice, held by the Vendor for 7 years. Panel of 900. Gross cash receipts nearly £1,700. Fees from 3/6. Centrally situated house, with 3 reception, 6 bedrooms, etc. Net rent, on lease, £90 p.a. Premium 2 years' purchase.
6. SOUTH COAST TOWN.—PARTNERSHIP.—A one-third share (with increase later) is offered in a mainly better-class non-panel Practice. Average gross cash receipts for the past three years £4,150. Fees from 10/6. Not much midwifery. Well-situated house, with 3 reception, 8 bedrooms, etc. Can be rented on lease at £135 p.a. Premium 2 years' purchase.
7. MIDDLESEX.—Steadily increasing middle and working-class PRACTICE, producing this year at the rate of £800. Panel of 250. Fees from 5/-. House contains 2 reception, 4 bedrooms, etc. Price for freehold £1,650, part on mortgage. Premium £850.
8. WITHIN 20 MILES OF LONDON (WEST).—Well-established rapidly increasing PRACTICE, in very pleasant growing residential district, offering excellent future prospects. Cash receipts last year £1,700, including small panel of 150. No dispensing. Visits 5/- upwards; mids. from 4 gns., about 40 cases. Good house (3 reception, 5 bedrooms, etc.), in half an acre of garden, with tennis court. Garage. Price, freehold, £1,850. Premium £2,100. Cottage Hospital. Ill health reason for selling.
9. ESSEX.—Very old-established PRACTICE, situated in pleasant country district, in growing area about 30 miles from London, and few miles from the sea. Cash receipts average nearly £900 p.a., including panel of 600. House contains surgery and waiting room, 3 reception, 5 bedrooms, bathroom, etc. Garden. Garage. Gas, but electric light available. Moderate rental. Premium 1½ years' purchase.
10. LONDON, EAST.—Very old-established working-class PRACTICE, averaging for past twelve months over £2,300, including panel of over 2,800. Good appts. worth nearly £160. Visits from 2/6. Very low expenses. Suitable house can be rented or purchased. Central surgery can be rented. Premium £4,250.
11. LONDON, WEST.—Old-established good middle-class PRACTICE, averaging over £2,500 p.a. (last year £2,600), medium-sized panel. Visits 5/- to 10/6 and occasionally 21/-. Midwifery discouraged; 2 or 3 cases yearly at 15 to 20 gns. House contains professional accommodation, 2 reception, 5 bedrooms, dressing rooms, etc. Leasehold (23 years to run at nominal ground rent). Price £1,650. Premium £4,475.
12. NORTH DEVON AND CORNWALL BORDERS.—Very old-established unopposed Country PRACTICE, in beautiful district near the coast. Cash receipts average just over £1,100 p.a., including appt. and panel of 330. Suitable house available. Premium £1,600, to include drugs, etc. Hunting, golf, fishing, tennis, etc.
13. MIDLANDS.—COUNTY TOWN.—PARTNERSHIP.—A one-fourth share is offered in an exceptionally sound good mixed-class Practice, averaging over £6,000 p.a., including panel of 3,400. Lowest fee 4/-. Very little midwifery. If single, purchaser can live in comfortable rooms; otherwise choice of houses for sale, or on rental. Premium 2 years' purchase.
14. PARTNERSHIP.—YORKSHIRE.—LARGE CITY.—A one-third share with succession to the whole Practice in about one year's time, is offered in a rapidly increasing PRACTICE, producing for the last 12 months approximately £2,300, including panel of 1,500. One appt. worth £150. A suitable house will be vacant shortly. Premium £1,200. Large scope for further development.
15. LONDON, N.W. (Kentish Town area).—In a well-populated district a mainly working-class PRACTICE, producing for 12 months ending March last £728, including panel of 260. House contains 10 rooms; small garden; garage. Rent £120 p.a. on lease. Premium £900.
16. LONDON (WEST END).—Old-established non-dispensing and non-panel PRACTICE, averaging over £4,700 p.a. Visits (very few) and consultations from one guinea upwards. No midwifery. Suitable accommodation available on rental. Premium £6,000. Good introduction given. Personal application desired.
17. WITHIN 20 MILES OF LONDON (WEST).—Rapidly developing district.—PARTNERSHIP.—A half share in a well-established good middle-class Practice, averaging over £3,500 p.a. Panel of 1,100 and appts. worth £100 p.a. Fees 3/6 to 21/-. Good corner house, with 3 reception, 6 bedrooms, etc. Garden. Price for freehold £2,100. Premium 2 years' purchase.
18. SURREY.—COUNTRY PRACTICE.—Very old-established, and situated in delightful district. Gross cash receipts for past 12 months £2,000, including panel of about 700. Fees from 2/6 to 21/-. Midwifery 3 to 20 gns. Exceptionally nice house, with 2 reception, 6 bedrooms, and professional rooms. Nearly 2 acres of garden. Price for Practice and house £5,000.
19. CHESHIRE.—NEAR COAST.—Old-established good mixed-class PRACTICE, averaging for the past 3 years nearly £1,600, including panel of 1,280. Very good house in 3 acres of ground, with 2 reception, 4 bedrooms, etc. Rent on lease £85 p.a. Premium £2,300.
20. PARTNERSHIP.—HOME COUNTY.—Within 40 miles.—In a small country town, in very pleasant district, the third share, with increase later, of an old-established mixed-class Practice offering good scope. Cash receipts average over £3,000 p.a., including panel nearly 1,700 and appts. Good house, with 3/4 of an acre of garden, tennis court, etc. Rent on lease £65 p.a. Premium £1,700. Ingoing partner should be about 30, English or Scotch, and pref. married.
21. WITHIN 30 MILES OF LONDON.—In a delightful residential district (well populated and growing rapidly), a small PRACTICE, producing last year £406, including panel of 300, and capable of considerable development. Very good residence (suitable for resident patients) in about 2 acres of ground. Price, freehold, £4,000. Mortgage arranged. Premium £400. Excellent schools, good society, and sport.
22. FAVOURITE COAST TOWN.—Old-established good middle and better-class PRACTICE, producing over £1,800 p.a. Selected panel of under 400. Fees 3/6 to 10/6. Very little midwifery. Commodious house, with 2 reception, 6 bedrooms, etc. large garden. Freehold for sale. Premium £3,000.
23. SOUTH OF ENGLAND.—Pleasant Town near sea coast.—Very old-established PRACTICE (partly Surgical), averaging over £2,400 p.a. (last year £2,516), including panel of 500. Centrally situated house. Price for Practice and house £5,000. Successor should also have some knowledge of Eye, Ear, Nose, and Throat work.
24. HOME COUNTIES.—Within 40 minutes' run of London.—Old-established mixed-class and increasing PRACTICE, situated in small town with pleasant surroundings. Cash receipts average £1,725 p.a., including appt. £70 and panel 1,000. House with good accommodation and small garden. Price for freehold £2,500. Premium 1½ years' purchase. Educational facilities.
25. SOUTH AFRICA.—Within 8 hours of Durban.—Rapidly increasing PRACTICE in very pretty township near sea coast, producing last financial year over £1,700, including appt. £120. Practically all fees, which are good, are paid in cash. Opposition negligible. Bungalow residence in about one acre of ground. Rent £84 on lease. Premium £1,500, to include furniture, drugs, instruments, and motor car (£1,325 without latter), payable £1,000 down and balance by easy instalments. Excellent climate and sport.
26. NORTH WALES.—PARTNERSHIP.—A one-third share is offered in a good mixed-class Practice producing over £1,700 p.a., including panel of 470 and appts. of about £100 p.a. Fees 3/6 to 21/-. Purchaser, if bachelor, could reside with Vendor. Good sport and schools. Premium 2 years' purchase.
27. SURREY.—Increasing residential district, with good train service to town.—Well-established good general PRACTICE, offering Surgical scope. Gross cash receipts for last 12 months nearly £3,200, with panel of about 900. Visits 5/- to 21/-. Suitable house, with 3 reception, 7 bedrooms, etc. Can be bought or rented on lease. Premium 1½ years' purchase.
28. SOUTH CORNWALL.—Near Sea.—Well-established PRACTICE producing about £700 p.a., including panel of over 600. Fees 5/- to 21/-. Suitable house, with 3 reception, 5 bedrooms, etc. Rent on lease £50 p.a. Good sport and mild climate. Premium only 1 year's purchase. Ill-health reason of sale.
29. LONDON, SOUTH-EAST. — Woman Doctor's PRACTICE, producing £560 immediate past 12 months. Panel of 152. Fees 2/6 to 21/-. Suitable flat can be rented at £60 p.a. Premium £650, or near offer. Very good scope for increase.
30. NORTH LINCS.—COAST TOWN.—Old-established PRACTICE, producing last year nearly £2,900 p.a., including panel of 1,700. Fees 3/6 to 21/-. Practically unopposed. Good modern house, with special professional rooms. Nice garden. Garage. Freehold for sale, part on mortgage. Good sport and schools within reach. Premium 1½ years' purchase
31. NORTH OF ENGLAND.—GOOD TOWN.—A one-third share is offered in a very sound PRACTICE averaging about £5,000 p.a. Ingoing partner must be well qualified, not over 35, and interested in medicine. Suitable house available. Premium 2 years' purchase.

Full Schedule of Terms and Conditions will be forwarded on application.

Printed and published by the British Medical Association, at their Office, Tavistock Square, in the Parish of St. Pancras, in the County of London.

MILK POWDER *for* SAFETY!

The following extracts from *The Lancet*, and the Presidential Address at the Royal Sanitary Institute Congress at Margate, show the risk run in feeding raw milk to infants:

'There can therefore be no doubt that a fair proportion of cases of ordinary adult phthisis in Scotland are due to the bovine bacillus .....'—*The Lancet*

.... 'But when to this is added the fact that in England 31.5 per cent. of tuberculosis in children up to 15 years of age is of bovine origin, and deaths from tuberculosis in children up to 5 years is 29.5 per cent. of bovine origin, that 57 per cent. of cervical adenitis in the same ages is of bovine origin, that 33 per cent. of bone and joint tuberculosis in children under 5 years and 24 per cent. in children from 5 to 10 years is of bovine origin, that in Scotland it is recorded that in certain hospitals in Edinburgh as much as 90.3 per cent. of cervical adenitis and 61.2 per cent. of bone and joint tuberculosis in children up to 12 years is of bovine origin, it is high time that this grave condition and this very serious menace to public health should be mended and ended.'

Extract from Presidential Address, Royal Sanitary Institute Congress, Margate.

Extract from the Annual Report for 1928 of the Medical Officer of Health for———

INFANTILE DIARRHŒA

"Until the methods of farmers and others concerned in the milk industry have been revolutionised, and consumers have been provided with facilities for storage and education in the handling of milk, *I am definitely of the opinion that liquid milk should be banished from the dietary of infants.*"

Many such extracts show that the opinion of the Medical profession is rapidly turning to the use of specially prepared Milk Foods in infant feeding as the only safe and suitable substitute for breast milk.

Cow & Gate Milk Food

"The best milk for babies, when natural feeding fails."

COW & GATE MILK FOOD

is prepared by our Special Improved Roller Process employing a short heat treatment which destroys all disease organisms but leaves the natural vitamins and minerals unimpaired. *It is a basic milk food which can be modified by the profession as they desire to suit all and every case.*

BRITISH BRITISH

Elastoplast

(Patent 253,527)

THE ORIGINAL & FINEST ELASTIC PLASTER

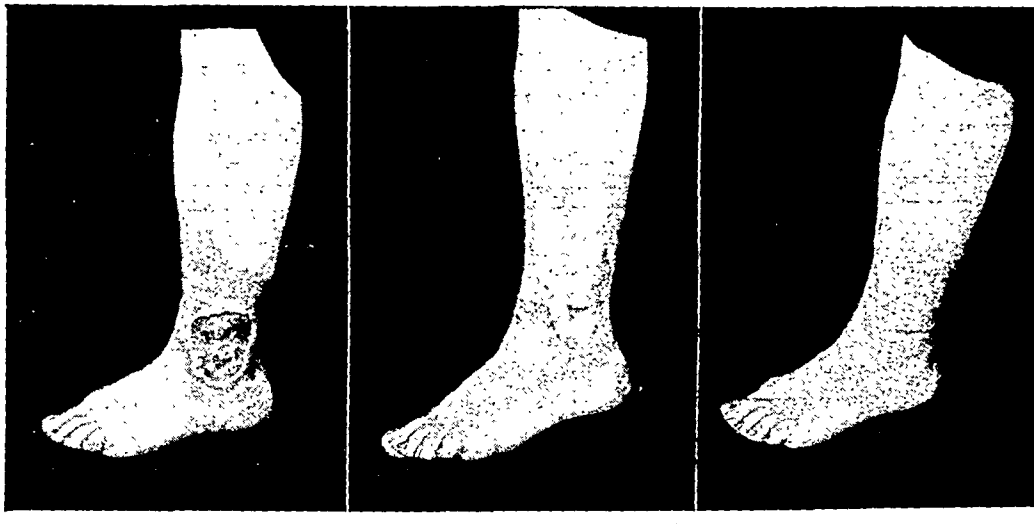
The cure of Varicose Ulcer by means of Elastoplast Bandages is now practised in nearly every Hospital in the British Isles, and 100% cure of cases is achieved.

In certain cases of Varicose Veins where on account of systemic disease, or the patient's timidity, a curative course of injection cannot be given, then the veins can be kept obliterated by Elastoplast.

Elastoplast is also extensively used for general surgical and orthopaedic work.

As a support for varicose veins, sprains, strains, dislocations, after-treatment of fractures, weak joints, flat or dropped foot, etc., Elastoplast is unequalled.

Manufactured from the finest yarns, Elastoplast is the only Elastic Plaster having the correct degree of elasticity, thus ensuring perfect compression and support.



Woman patient aged 55. After 12 weeks' treatment. After a further 2 weeks.

The only treatment consisted of Elastoplast Bandages, changed weekly at first, and later fortnightly.

Other Elastoplast Specialities include:—Finger Dressings, Wound Squares, Wound Strips, Boil Dressings, Eye Dressings, Vaccination Dressings, etc., all on the pliable Elastoplast base, with medicated pads. Elastoplast will reduce your Dressings Accounts, save you valuable time, increase the efficiency of the injured person, and, moreover, ensure cleanliness. Also—VISCOPASTE BANDAGES (improved Unna's Paste Type), Adhesive Gelatine Bandages.

Literature and cuttings will be sent on application, or a trial set containing full Bandages and a range of Dressings upon receipt of P.O. value 2/6 (Overseas postage extra) by the manufacturers:

T. J. SMITH & NEPHEW, Ltd.

HULL. LONDON. GLASGOW. MANCHESTER.

Enquiries to—Dept. B, 42, Tavistock Square, London, W.C.1.

ELASTOPLAST MAY BE OBTAINED FROM YOUR USUAL SURGICAL SUPPLY HOUSE.

BOURNE'S RECENT ADVANCES IN OBSTETRICS & GYNAECOLOGY

Second Edition. 67 Illustrations. 12s. 6d. Postage 6d.

By A. W. BOURNE, F.R.C.S., Obstetric Surgeon, St. Mary's and Queen Charlotte Hospitals.

"... useful and readable, and Mr. Bourne will receive the thanks of many of his colleagues for the work which he has put into it."—BRITISH MEDICAL JOURNAL.

THE QUEEN CHARLOTTE'S PRACTICE OF OBSTETRICS

Second Edition. 4 Coloured Plates, 274 Text-figures. 18s. Postage 9d.

By the following members of the Hospital Staff: J. BRIGHT BANISTER, ALECK W. BOURNE, T. B. DAVIES, C. S. LANE-ROBERTS, L. G. PHILLIPS, L. C. RIVETT.

London: J. & A. CHURCHILL, 40, Gloucester Place, Portman Square, W.1

DISEASES OF THE HEART

THEIR DIAGNOSIS, PROGNOSIS, AND TREATMENT BY MODERN METHODS.

With chapters on the Ink Polygraph, Clinical Electro-Cardiography, X-Ray Examination, and Anaesthesia in Relation to Cardio-Vascular Affections.

By FREDERICK W. PRICE, M.D., F.R.S.(Edin.), Senior Physician to the National Hospital for Diseases of the Heart; Consulting Physician to the Royal Northern Hospital, London.

Demy 8vo. Pp. 534. With 249 text figures, including 32 sphygmograms, 92 polygraphic tracings, and 87 electro-cardiograms.

NEW SECOND EDITION, 21s. net.

"By great care and by the use of an amazing amount of material, he has accomplished what many readers have been waiting for, giving us a complete account of the diagnosis, prognosis, and treatment of heart diseases by modern methods in association with all the invaluable teaching bequeathed to us by the older masters of clinical observations."—LANCET.

"The most valuable guide to the study of Cardiology with which we are acquainted."—NEW YORK MEDICAL JOURNAL AND RECORD.

"We think that most of our readers engaged in general practice will find this work extremely useful."—THE JOURNAL OF CLINICAL RESEARCH.

"In our opinion the book is indisputably the most authoritative contribution to cardiology of our time."—FRANCO-BRITISH MEDICAL REVIEW.

"A book which we believe is destined to remain the standard work on Cardiology for many years to come."—AMERICAN MEDICINE.

"The second edition of this popular work on heart disease bears evidence of thorough revision, while the essentially clinical standpoint of the writer is maintained."—EDINBURGH MEDICAL JOURNAL.

"It may be said at once that the book adequately fulfils the purpose it has in view, and is a perfectly sound, lucid, and reliable guide."—NEWCASTLE MEDICAL JOURNAL.

"Well-written, concise, and complete, containing a wealth of practical information. Obviously based upon the author's own experience and investigative work."—SURGERY, GYNECOLOGY, AND OBSTETRICS (Official Journal of the American College of Surgeons).

"Dr. Price is to be congratulated again on the reappearance in its second edition of his distinguished contribution to the increasingly important subject of Cardiology."—THE CANADIAN JOURNAL OF MEDICINE AND SURGERY.

OXFORD UNIVERSITY PRESS, Amen House, Warwick Square, London, E.C.4.

ARE YOU SATISFIED with YOUR BOOK-KEEPING SYSTEM?

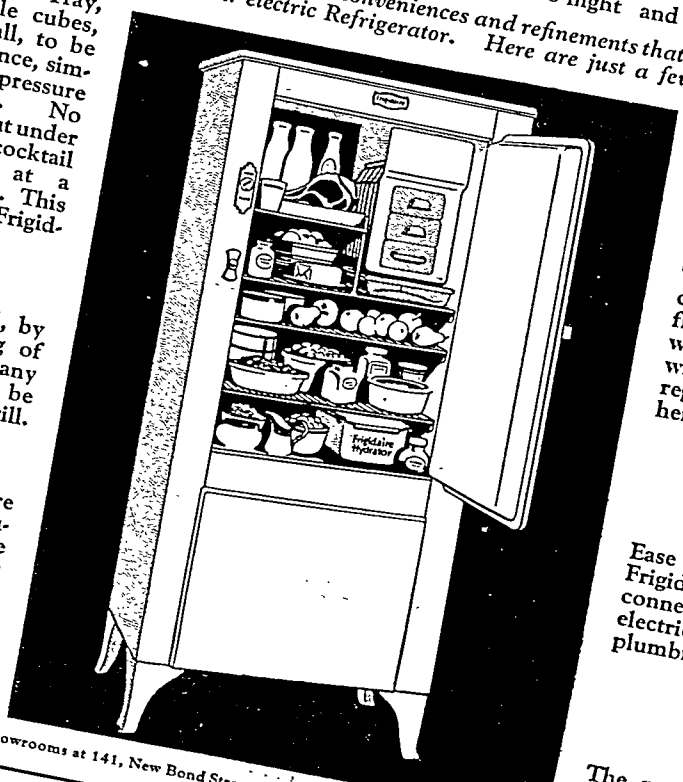
KEROL CAPSULES

You're always taking temperatures . . . but do you ever take the temperature of your own Larder?

JUST try the experiment. Remember that over 50° for your food is just as bad as over 100° for your patient. Over 50°, bacteria multiply in food 400 times faster than at temperatures below. And, apart from the health reasons, wouldn't it be comforting to know that your food was kept cold and appetising and fresh, in a snow-white all-porcelain Frigidaire, shut away from the dirt and flies, *automatically* prevented from "going off"? Perhaps you've been promising yourself a Frigidaire—then send in the coupon to-night and see how little it costs!

Frigidaire incorporates all the conveniences and refinements that you would wish to have in your electric Refrigerator. Here are just a few of them.

The Quickube Ice Tray, enabling single cubes, or many, or all, to be extracted at once, simply by a light pressure of the finger. No melting them out under the tap. Your cocktail ice is ready at a moment's notice. This is an exclusive Frigidaire feature.



Practical flat top, makes a useful shelf.

The Hydrator—a *moist* cold compartment, for fresh vegetables, sandwiches, etc. Even wilted vegetables will regain their crispness here in a few hours.

The Cold Control, by which the freezing of ice cubes or any frozen delicacy can be accelerated at will.

The automatic feature of Frigidaire is invaluable. It cuts out the human element with its forgetfulness and consequent waste. Frigidaire maintains a dry cold that is *always* under 50°—the only safe temperature for food.

Ease of installation. A Frigidaire only needs connection with your electric supply. No plumbing is necessary.

The new Frigidaire is quiet—you can't hear it start, stop or run.

Showrooms at 141, New Bond Street, London, W.1, and in all principal towns.

FRIGIDAIRE LIMITED (*Incorporated in Canada*), Dept. BG 276 Edgware Road, The Hyde, Hendon, N.W.9

COUPON

Please give me by return, without any obligation on my part,

(*a*) Price of Frigidaire cabinet suitable to my particular needs; or

(*b*) Particulars of your system of convenient deferred payments.

When a life is at stake.....

The psychological moment has arrived. Will the operation be successful? . . . Can modern science triumph over such disease? . . . The surgeon bends closer over the table . . . deft fingers touching slender instruments . . . a life is at stake . . . if the lights should fail, plunging the theatre into darkness . . .

Nowhere is reliable light supply more important than in operating theatres. A light failure may have far-reaching consequences. Every hospital should be equipped with Ediswan Stationary Battery. Then if current fails, a switch over to the Ediswan saves the situation and restores light almost immediately.

The Ediswan Stationary Battery for Emergency Lighting is compact and robust. It takes up little space and is sturdily built to give long service. Running costs are almost negligible. Installation costs are low.

May we co-operate with you in evolving a Battery specially to suit your requirements?

THE EDISON SWAN ELECTRIC CO. Ltd.

DISMENOL for instantaneous relief of pain in DYSMENORRHOEA

In spasmodic Dysmenorrhoea the primary call is for the elimination of pain, and the physician has a valuable weapon in Dismenol Tablets, which are entirely *free from narcotics.* This product is a sure and safe sedative in all cases of Dysmenorrhoea, possessing anti-spasmodic properties of a remarkable kind. A feeling of general well-being is substituted for the state of lassitude in the patient.

Please write for samples and literature (also formula) to—

ROBERTS & Co., 76, NEW BOND STREET, LONDON, W.1.

Pharmaciens to H.M. the King.

TO COUNTER ACIDOSIS

As SALVITAE contains 59% of Potassii et Sodii Citro-Tartras and 30% of Sodii Sulphas it is of great value both in maintaining health and in the treatment of disease, through eliminating deleterious nitrogenous products and favourably influencing circulation, glandular secretions, peristalsis, and *metabolism.*

The fruit acids of SALVITAE are converted in the system into potentially basic alkaline carbonates, thus enabling the blood to keep the uric acid compounds in solution, and facilitate their removal.

NOVOCAIN

The Original Preparation
English Trade Mark No. 276477 (1905)

Local Anæsthesia in Surgical Practice

OPERATION ON NECK AND REMOVAL OF TESTICLE.

Typical Case.

S. J., male, aged 72 years.

Diagnosis: (1) Tuberculous cervical adenitis. (2) Tuberculous epididymitis and orchitis (right side).

Operation: (1) Block dissection of neck. (2) Right orchidectomy.

Anaesthesia: 77 c.c. of 0.5 per cent. Novocain-Adrenaline solution.

Operation: An infiltration block of the ilio-inguinal and ilio-hypogastric nerves, and as the cord was exposed it was thoroughly infiltrated. The pudic nerves were blocked, and the tuberculous testicle and epididymis were removed. The patient was allowed to leave the hospital in a few days, and he returned on March 3rd, 1920, at which time he had a complete dissection of the right side of his neck, using 120 c.c. 0.5 per cent. Novocain-Adrenaline solution.

—EXTRACT from PRACTICAL LOCAL ANAESTHESIA (Farr).

(Full technique of this and one hundred other operations under Local Anaesthesia will be found in the above work, published by Henry Kimpton, 263, High Holborn, London, W.C.1.)

THE SAFEST LOCAL ANAESTHETIC.

Ample supplies of Novocain are available for the use of Surgeons at all the chief Hospitals. Specify "Novocain" for your next operation.

Does not contain Cocaine, and does not come under the Dangerous Drugs Act.

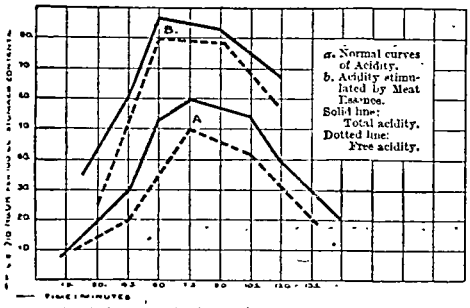
Conserves the patient's energy—
no strain on the digestive system
when these essences are taken



Graph showing acidity found when meat essences are taken

BRAND'S

ESSENCES OF BEEF

OR CHICKEN

When the appetite needs stimulus, and the body needs to be invigorated without demands on the digestive system, Brand's Essences of Beef or Chicken have been found to be indispensable. Recent scientific tests have shown that these essences are assimilated by the digestive organs *forty minutes quicker* than ordinary foods and without the formation of any residue.

In convalescence and in all cases of intestinal disturbances, whether the lesion is catarrh or cancer; in states of exhaustion when the patient's recovery is hampered by anorexia; in specific fevers and in all disorders associated with pyrexia; in the post-influenzal state and before and after operations, these Essences supply energy and prepare the system to accept and digest a more solid diet.

Hygienically prepared by an exclusive process from the finest freshly-killed English meats, Brand's Essences of Beef or Chicken are suave and non-irritant in action. For these reasons 99 doctors out of every 100 recently interviewed, recommend them. Samples will be gladly sent on receipt of a professional card. Brand & Co. Ltd., Dept. F36, Mayfair Works, South Lambeth Road, London, S.W.8.

Proverbs Up-to-date No 1

FAMILIARITY BREEDS CONTEMPT

Are we not, at times, inclined to allow practical activities to cloud our perception of the familiar fact, that Dental Caries is an almost *incurable* disease?

As every doctor knows, this is one of those pathological conditions that show little, if any, tendency towards spontaneous cure, or even arrest, of its ravages.

The only scientific method of combating this affection is through preventive measures. And it is this truth that is the keynote of all Gibbs Advertising propaganda. Care of the teeth, cleanliness of the mouth, are urged as first principles.

In the great national and provincial newspapers; in the most widely read magazines, many millions of Gibbs messages are carried from end to end of the kingdom. And every message can be crystallised in that oft'-repeated phrase: "Visit your Dentist twice a year, and use Gibbs Dentifrice twice a day."

It is in such practical ways as these that Gibbs work hand in glove with Doctors and Dentists — never failing to depict them as the highest and final authorities on all matters connected with the teeth.

GIBBS DENTURE TABLET

Gibbs new Denture Tablet is for cleaning Dental Plates (both gold and vulcanite), Bridgework and artificial teeth. It gives a high polish, removes stains, makes plate or teeth sterile and antiseptic without in any way injuring the softest gold or the finest vulcanite or platinum. The product has been approved by important members of the Medical Profession.

TABLETS "B.S.C."

(Bile Salt Compound)

TRADE MARK

For Constipation, Intestinal Toxæmia, Hepatic Deficiency, Gall Stones and allied conditions.

Tablets "B. S. C." contain active pancreatic extract and bile acids, extract of duodenal mucous membrane and a proportion of ipecacuanha and emodin. Their administration stimulates the flow of glandular secretions which complete the digestive processes; the bile salts emulsify and detoxicate the food residue, while the emodin and ipecacuanha exert a tonic effect on the visceral musculature, particularly the colon, thus stimulating peristalsis.

Tablets "B. S. C." are of particular value in the treatment of constipation, hepatic disorders and the toxæmias arising from stasis. In conjunction with hexamine, they are of distinct benefit in the treatment of gall-stones and cholecystitis.

Supplied in bottles containing 40, 80, 160 and 500 at 2/6, 4/6, 8/6 and 20/-

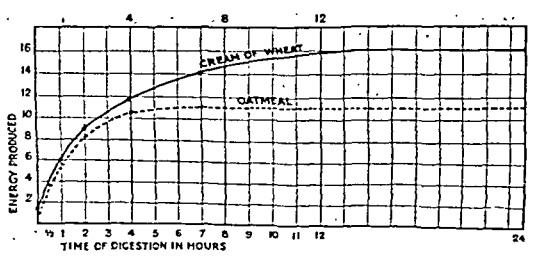
DIMOL LABORATORIES Ltd., 40, Ludgate Hill, London, E.C.4

Produces 1½-times as much energy and is more digestible

Tests carried out at a famous Research Institute prove the superiority of this wheat cereal over oatmeal



The graph above illustrates the greater digestibility and energy value of wheat, as opposed to oats. Tests showed that after 4 hours the digestion of oatmeal was almost at a standstill, while that of "Cream of Wheat" continued at a scarcely diminished level for another 4 hours. When digestion was complete, the sugar yield from "Cream of Wheat" was 50% greater, and productive therefore of 1½-times as much energy.

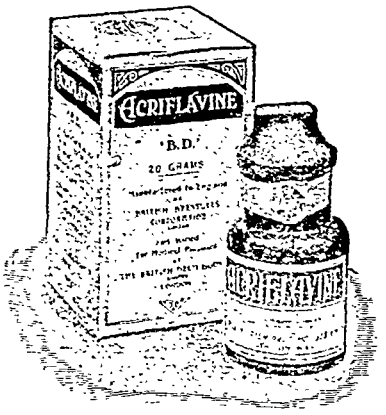
The superiority of "Cream of Wheat" over oatmeal as a first starch food for infants has been conclusively proved by a series of experiments recently conducted in the laboratories of a leading biochemical Institute.

"Cream of Wheat" prominent on the diet sheets of leading British pediatrists.

Made from the granulated endosperms of the best hard wheat, "Cream of Wheat" contains 72 per cent. starch, the importance of which in the feeding of infants is now generally recognized. "Cream of Wheat"—with this high starch content, its energy output, and its amazing ease of assimilation—is prominent on the diet sheets of leading British pediatrists.

No outside husk of the wheat grain is used in the manufacture of "Cream of Wheat," consequently there is nothing in this product to cause irritation to the intestinal tract. It can be given with assurance, not only to infants from the weaning stage, but also to adults during the post-operation period and convalescence. A professional card will bring you fuller details of the above tests, and a sample of this cereal. Dept. W.6, Fassett & Johnson, Ltd., 86, Clerkenwell Road, London, E.C.1.

"CREAM of WHEAT"



In Septic Conditions

Acriflavine is an antiseptic of unusually wide application.

Originally employed as a wound dressing, it has now become the antiseptic of choice in the treatment of gonorrhoea; it is of recognised value also in dermatology, in dentistry, in ophthalmic surgery and in general conditions of sepsis.

Acriflavine "B.D."—the proven British brand—holds its supreme position among other brands of Acriflavine because of its purity and its efficacy in use.

Acriflavine "B.D." is issued in powder form, also in tablets, in solution, in an ointment, in bougies and in suppositories.

SOYOLK

is a pure natural product, free from chemicals, and is quite different in its composition from ordinary wheaten or any other flours, since it contains 20% of easily digestible fat, and 43% of biologically high-grade protein. This protein is highly assimilable and has proved to form a perfect substitute for animal protein.

In addition, there is 2% of the organic phosphate lecithin apart from phosphatic salts and the Vitamins A, B, D & E. SOYOLK contains NO STARCH.

It is, therefore, a product of extraordinary high food value; by the incorporation of Soyolk the nutritive value of the common farinaceous foods (bread, confectionery, puddings, etc.) can be greatly enhanced and the protein deficiency, which is a marked characteristic of the usual cereal products, be remedied.

The following are a few testimonials:—

Prof. Dr. Leopold Moll, Director of the Austrian Government's Institute for the Care of Mothers and Babies in Vienna, states:—

"In order to give a food very rich in proteins for certain diseased conditions, particularly in cases of malnutrition of babies and infants, we administered puddings made up with Soyolk. Especially with Tuberculous children the Soya-feeding was a great success. We also fed such children with Soyolk who either did not take cow's milk well, or were unable to digest it properly.

In cases of lack of appetite, we gave Soyolk in order to concentrate the food. Soya given twice daily was well taken by infants in a state of bad nutrition."

A Noted British Professor on Household and Social Science:—

"I received your two loaves safely and consumed them in my family. I am pleased to say that they were much appreciated; we liked the flavour, texture, and keeping qualities of the bread. I am extremely interested in increasing the protein intake of people, and think that Soya Bread is an excellent way of *attaining that end.*

I think there is a great future for Soya products."

A Noted British Sanatorium:—

"I am very pleased to inform you that we have used this product ever since blended in our bread flour, *with very beneficial results to both patients and staff of our three Sanatoria.*"

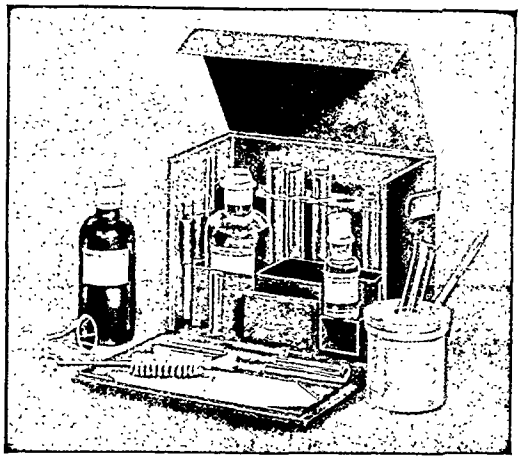
B.D.H. UREAMOMETER OUTFIT



It has been pointed out (*B.M.J.*, June 20th, 1931, pp. 1064-1067) that there is perhaps no condition in medicine which so frequently gives rise to difficulties and mistakes in diagnosis as that known as uraemia.

The B.D.H. Ureamometer Outfit provides in compact form all that is required for the estimation of blood urea.

The estimation can be carried out in 35 to 40 minutes at any time within 24 hours of the taking of the sample of blood, a single drop from a finger prick being sufficient for the test. No equipment other than that contained in the outfit is required, and no titrations or calculations are involved, the results being read off directly by colour comparison.

Liver Therapy in ANAEMIA

The haemopoietic value of liver manifests itself clinically in a most rapid and convincing manner, and it is now recognised that various fractions exist, having separate and distinct characteristics.

HEPATEX

This is the liquid extract of liver made at Evans' Biological Institute. Introduced for the treatment of pernicious anaemia, in which it has been proved highly satisfactory, its success in the severe secondary anaemias has been so pronounced as to warrant investigation, which shows that **HEPATEX contains the full Vitamin B complex,** the various components of which must assuredly be of great therapeutic value. It may well be that the usefulness of HEPATEX in the secondary anaemias is due to this factor. HEPATEX is prepared and concentrated so that a teaspoonful dose contains the full therapeutic principles of 2 ozs. of fresh liver.

Issued in 4-oz. bottles.

Prepared at EVANS' BIOLOGICAL INSTITUTE, Higher Runcorn, Cheshire.

Continued—

HEPATEX P.A.F.

Announcing a new highly concentrated solution of the liver fraction effective by intramuscular or intravenous injection in the treatment of Pernicious Anaemia.

HEPATEX P.A.F. has been subjected to clinical trials which have been completely satisfactory. As we go to press we have received the record of a further case of Pernicious Anaemia admitted to hospital *in extremis*. The ordinary treatment of blood transfusion was obviated by the prompt initiation of HEPATEX P.A.F., and the response was immediate, the Reticulocytes showing an increase within a few hours and rising to 42% in seven days.

It is not intended that Hepatex P.A.F. should replace Hepatex, which has been proved so efficacious for oral administration in the great majority of cases, but rather is it offered as a companion product for use in those cases where oral liver therapy is not desirable or only partially effective, or when extreme speed of action is essential.

Dosage varies from 5 c.c. per week to 5 c.c. per day according to the severity of the case.

Supplies are now available.

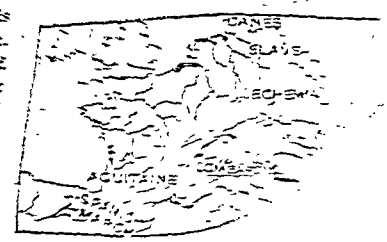
THE VAST TEUTONIC EMPIRE OF CHARLEMAGNE.—Charlemagne was the first to visualize Europe as an organic whole. His wars were not waged primarily for the sake of conquest and expansion; his aim was to make the Frankish empire secure by incorporating within its borders the territories in which dwelt its enemies. First Aquitania was conquered and annexed, then at the entreaty of Hadrian, Bishop of Rome, the Lombard kingdom in Italy and the Moslems and the Spanish March; then, later, in the north-east, the Slavs—known as the Wilzi—were driven back, and so, in their turn, were the Avars, the Bohemians and the Danish pirates. The kingdom of the Franks was great and strong when he inherited it from his father, Pippin, but the additions he made almost doubled it. Charlemagne protected the empire by forts and garrisons and by establishing a fleet. It was due to these precautions that Italy suffered no serious harm from the Moors, nor Gaul and Germany from the Northmen, in Charlemagne's reign. In the course of time various national states—France, Germany, Flanders—were to take shape within this framework, the outline of Europe, traced by the first western emperor.



DATE: A.D. 768–841 *Charlemagne's reign*

The Gargle and the Child

WHILST medicine, though unpleasant to take, can be forced on the unwilling child, it is not so simple a matter to compel a child to gargle. The act of gargling cannot be enforced, and, where the actual gargle is disagreeable, few children will submit. Therefore, a very necessary act is often scamped or entirely avoided.

ODOL Mouthwash very successfully solves this problem. Its very pleasant taste appeals to the child and its proven bactericide efficiency achieves the desired results. Moreover, Odol is absolutely harmless and cannot injure the delicate mucous membrane of the child's mouth.

Observations ON A CEREBRO-SPINAL FEVER OUTBREAK IN THE ROYAL AIR FORCE IN 1931

BY

WING COMMANDER H. E. WHITTINGHAM, C.B.E., M.B., F.R.C.P.ED., D.P.H.

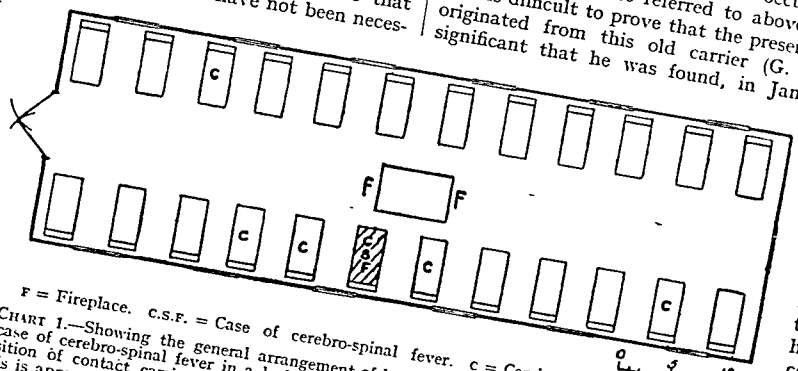
FLIGHT LIEUTENANT J. M. KILPATRICK, M.B., B.CH.

AND

FLYING OFFICER E. W. B. GRIFFITHS, M.B., CH.B.

ROYAL AIR FORCE MEDICAL SERVICE

Since 1919 there have been sporadic cases of cerebro-spinal meningitis in the Royal Air Force, chiefly among recruits, and the bacteriological examination of swabbings from the nasopharynx of the more immediate contacts has resulted in the prompt detection and consequent isolation of meningococcus "carriers" in each instance. The spread of the disease has been arrested, possibly by this speedy isolation of carriers, or by good fortune, so that more stringent prophylactic measures have not been necessary. But in the beginning of the present year there occurred a series of cases of cerebro-spinal fever of the fulminating type which were not so readily controlled, and during the investigation of this outbreak certain interesting observations were made regarding the origin, spread, and control of the infection and the treatment of the disease.



F = Fireplace. C.S.F. = Case of cerebro-spinal fever. C = Carrier of meningococcus.

CHART 1.—Showing the general arrangement of beds in barrack rooms and the occurrence of a case of cerebro-spinal fever in a bed in close proximity to the fireplace (see text). The position of contact carriers of meningococcus is also indicated. The space between adjacent beds is approximately 3 feet.

HISTORY OF THE OUTBREAK

The outbreak occurred at Uxbridge, and was coincident with an influx of new recruits of susceptible age, the advent of cold, foggy weather, and the issue of a more liberal coal allowance to mitigate the rigours of the winter. The provision of fires in the barrack-rooms led naturally to a crowding together of men around the fireplace in the evenings, and this appears to have played an important part in the dissemination of the infection; it was not purely a question of bed space. The first case occurred on January 4th, 1931, the second on January 5th, and then serially on the 8th, 17th, 24th, 25th, 27th, and 31st, and on February 7th, 10th, 11th, and 14th. In all, there were twelve cases of cerebro-spinal fever of the malignant type, and there was no direct connexion as regards infection between any of them, with the exception of the patients (Cases Nos. 9 and 11) who occupied adjacent beds; in all other instances the patients were drawn from widely separated barrack rooms. This distribution of cases pointed to some common source of infection, such as the cinema, concert room, or canteen. The isolation of contact carriers of the early cases, and the closure of the cinema and the cessation of other forms of indoor entertainment, did not check the spread of the disease. But on February 12th the canteen was closed, and a more extensive search was made for contact and non-contact meningococcus carriers throughout the depot. Following on this action the outbreak terminated abruptly within forty-eight hours.

ORIGIN OF THE INFECTION

The first patient in the present epidemic came from a barrack room in which there was an airman (G. T. C.) who had been isolated previously as a meningococcus carrier during the examination of contacts of a sporadic case of cerebro-spinal fever which occurred at Uxbridge in May, 1930. This carrier was then proved to harbour Type I meningococcus, and he continued to carry this organism for five weeks. After repeated nasopharyngeal swabbings were found to be negative, he was pronounced free from infection in July, 1930. He returned to duty at Uxbridge Depot on July 20th, and, despite his sojourn among other recruits, there was no recurrence of cerebro-spinal fever until the present outbreak, which commenced at the beginning of January, 1931, in a different barrack room from that which had been occupied by the patient in the sporadic case referred to above.

It is difficult to prove that the present outbreak of fever originated from this old carrier (G. T. C.), but it is significant that he was found, in January, 1931, to be still harbouring meningococci of the type responsible for the infection, and that he was a close contact of the first case. It is to be observed, however, that cerebro-spinal fever had been prevalent among the civil population since October, 1930, and that its incidence was increasing rapidly when the R.A.F. outbreak started; this factor undoubtedly added to the number of meningococcus carriers among the newly joined recruits, and so helped to bring the carrier rate at the Uxbridge Depot to the danger level.

SPREAD OF THE INFECTION

This raises the question of overcrowding in barrack rooms. There was no overcrowding as regards the actual bed space, and the barracks were well ventilated. The beds were spaced 2½ to 3 feet apart, and the windows were kept open day and night. Heating was attained by means of two open fireplaces situated towards the centre of each room. One or other of these fires was usually lighted about tea-time, and during the evening the inmates (twenty to twenty-four in number) naturally congregated at the fireside, so that in any barrack room, probably, the air was most impure in this region. It follows that those individuals whose beds occupied this central area continued to breathe this vitiated atmosphere longer than their room-mates, and it is significant that the first and all subsequent cases of cerebro-spinal fever, except Case No. 8, occurred in airmen occupying beds in close proximity to the fireplace in use (see Chart 1).

In this connexion it is interesting to compare the meningococcus carrier rate of newly joined recruits at Uxbridge and at Halton; in the seventh week of this year it was 15 per cent. and 3 per cent. respectively. The local heating arrangements may help to explain this

difference in the carrier rates. The airmen in both places are housed in barracks similar as regards cubic and floor space per man, but dissimilar as regards the mode of heating. The Halton barracks, which have been singularly free from cerebro-spinal fever, are centrally heated, so that each inmate tends to keep his own bed area, and there is no local overcrowding, whereas at Uxbridge the heating is by open fireplaces, leading to central crowding in each room, with results as described above.

Where did the men get the meningococcus into their upper respiratory passages with which to infect the air of the dormitories? As has been stated, the twelve cases occurred in separate barrack rooms (with one exception), indicating some common source of infection. Originally this infection may have taken place in one or in all of several places in which the airmen congregated—for example, cinema, dance hall, concert room, and canteen. The closure of all common meeting places, with the exception of the dining hall and canteen, together with the adoption of routine disinfection of the nasopharynx of all personnel by means of gargles, nasal douches, and sprays, as described later under "Control of the disease," did not stay the epidemic. Two obvious gaps were left in the chain of control—the dining hall and the canteen. In the dining hall the men of each barrack room sat at appointed tables, so that there was little likelihood of the inmates of one room infecting those of another here. In the canteen the men from different barrack rooms mingled freely in a warm and moisture-laden atmosphere, under social conditions conducive to the spread of disease by droplet infection; this was especially the case on a Friday (pay-day), for then the men flocked to the canteen. Strength is given to the supposition that infection took place chiefly in the canteen, and on a Friday, from the observation that cases of cerebro-spinal fever arose usually on the following Saturday, Sunday, Monday, or Tuesday—that is, within the recognized incubation period for the disease—and from the fact that the closure of the canteen was followed by the abrupt cessation of the epidemic (see Chart 2).

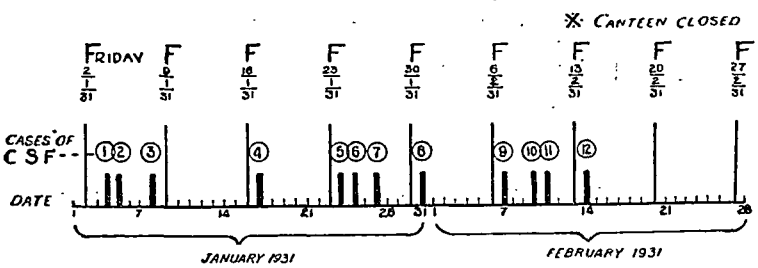


CHART 2.—Showing the relationship between the case incidence of cerebro-spinal fever and the crowding together of men in the canteen on Fridays—that is, pay-days.

A further isolated or sporadic case of cerebro-spinal fever occurred at the R.A.F. Depot, Uxbridge, on March 20th, 1931—that is, eleven days after the general prophylactic measures were relaxed. This patient, a recruit, had four days previously travelled 140 miles along with a number of his comrades in a closed charabanc. Infection in this instance presumably occurred from contact with meningococcus carriers during the long journey in a closed vehicle, as subsequently two carriers were detected among the passengers in the coach.

MENINGOCOCCUS CARRIERS

It has been established by Netter and Debré that the meningococcus carrier rate of a community bears a direct relationship to the development of cases of cerebro-spinal fever; the incidence and severity of the disease usually run parallel with the number of carriers. The outbreak at Uxbridge proved to be no exception to this rule.

Chart 3 indicates the meningococcus carrier rate and case incidence of cerebro-spinal fever among 542 recruits at Uxbridge during the first eight weeks of 1931. The percentage of carriers in the first week of January was 10;

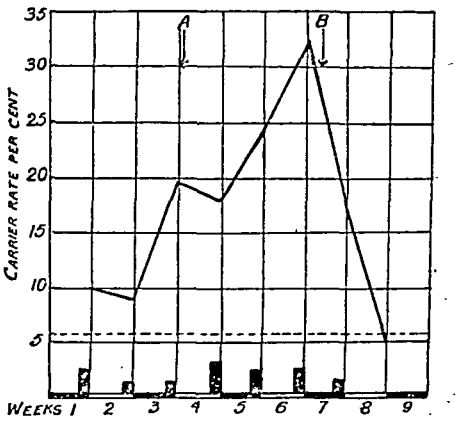

CHART 3.—Carrier rate shown by continuous black line. Cases of cerebro-spinal fever represented by vertical black columns. Upper limit of normal meningococcus carrier rate indicated by dotted line. A = Adoption of general prophylactic measures and closure of cinema. B, Closure of canteen.

during the third week it was 19½. The practice of general prophylactic measures, such as the spraying of the throats of all personnel, the isolation of all detected carriers, and the closing of the cinema, did not check the epidemic. By the sixth week of the year the carrier rate had reached 32 per cent. This was the acme, however, for in the seventh and eighth weeks, following on the closure of the canteen, the rate fell rapidly to 17 and 5 per cent. respectively. The case incidence of the disease rose and fell with the carrier rate, and ceased abruptly when this rate reached normal limits—that is, below 6 per cent.

In all, 120 carriers were detected and isolated, or, in other words, 22 per cent. of the recruits were found to carry the meningococcus. Moreover, the distribution of these carriers throughout the various barrack rooms was fairly uniform, as was shown by a general swabbing. Of these, 45 (37½ per cent.) were contact carriers, and 75 (62½ per cent.) were non-contact carriers. A contact carrier is defined as one who is known to have been in contact with a case of cerebro-spinal fever. This classification is unsatisfactory, as it is probable that many, if not most, of the so-called non-contact carriers had become infected from cases in the canteen or elsewhere. Most of the known contact carriers had been in very close relation to patients with the fever; they slept in adjacent or opposite beds, or had used the same cups, or had been intimate friends.

The duration of the infectivity of meningococcus carriers who are undergoing nasopharyngeal disinfection daily is of practical importance, and is indicated in Table I. It was found that 55 per cent. of the carriers were free from infection within three weeks, and 75 per cent. within a month. One carrier was of the chronic type; it was proved that he had harboured the meningococcus intermittently for the past ten months—that is, since May, 1930.

TABLE I.—*Showing the average length of time that meningococcus carriers, undergoing nasopharyngeal disinfection daily, carried the germ.*

Nasopharynx Clear of Meningococcus	Number of Carriers	Percentage of Carriers	
In 2 weeks	18	15	
3 ,, ...	48	40	75
4 ,, ...	24	20	
5 ,, ...	15	12½	25
6 ,, ...	15	12½	

The effect that the meningococcus had on the health of the carriers remains to be considered. None of the carriers, isolated as such, developed true cerebro-spinal fever, but 19 suffered from a pyrexia of the influenzal type and 26 had acute nasopharyngitis; whereas 75 remained apparently in normal health. If the twelve cases of cerebro-spinal fever be included, then 43 per cent. of the carriers showed signs of some acute infection, and 57 per cent. remained healthy; only 10 per cent. of the men who harboured the meningococcus in their nasopharynx contracted the specific meningitis. Table II amplifies these points, and indicates the varying degrees of immunity developed against the meningococcus; thus there may be health, a local throat infection, a more generalized sepsis, or actual meningitis and septicaemia.

TABLE II.—*Meningococcus Present in the Nasopharynx of 132 Men*

12 (9 per cent.) suffered from cerebro-spinal fever	43 per cent.	unhealthy carriers.
19 (15 per cent.) suffered from influenza		
26 (19 per cent.) suffered from nasopharyngitis...		
75 (57 per cent.) remained healthy	57 per cent.	healthy carriers.

MENINGISMUS

Those individuals who had pyrexia of the influenzal type accompanied by severe headache, together with tenderness of the neck muscles, and had meningococcus in their upper air passages, but not in their cerebro-spinal fluid, might have been diagnosed as suffering from meningismus or meningism—a condition referred to by Flack,[2] Horder,[3] and others during the war. In these cases the meningococcus was possibly the organism responsible for the infection, although Pfeiffer's bacillus was present also in many instances. It mattered little whether the diagnosis was meningismus or influenza, so long as it was recognized that these cases were not examples of cerebro-spinal meningitis, otherwise the serum, or whatever other treatment was given, might have been credited with unmerited curative power. This was not purely a matter of academic interest, but one of vital practical importance, as the therapeutic treatment of cerebro-spinal fever was, and still is, *sub judice*. In many instances a dose of antimeningococcus serum was given to a doubtful case pending the diagnosis; this was a justifiable and a wise measure to carry out during an epidemic of cerebro-spinal fever; in fact, the serum may have prevented the onset of meningitis in some cases. The problem, however, was to differentiate between meningismus or influenza and the early stages or milder attacks of cerebro-spinal fever.

DIFFERENTIAL DIAGNOSIS

The differential diagnosis of typical cases was easy, but many suspected cases called for a very careful clinical examination, together with a total leucocyte count of the blood and, at times, lumbar puncture. Special attention was paid to the mode of onset of the disease. Early onset of vomiting, especially if continued, severe headache, stiffness and tenderness of the neck muscles (this was best elicited in early cases by performing Kernig's test alone or in conjunction with Brudzinski's, and inquiring whether the patient felt any stiffness elsewhere than in the hamstrings), a varying degree of pyrexia, a pulse-respiratory rate of 3 to 1 or even 2 to 1, together with distinct nervous irritability, tache cérébrale, and inequality, dilatation, or contraction of the pupils were strong evidence of cerebro-spinal fever. Whereas in the influenza cases early and distinct pyrexia (103 to 105° F.) was the prominent symptom, there was little or no tenderness of the neck muscles, and the Kernig test was negative, the pulse-respiratory ratio was normal, nervous irritability was negligible, the pupils were normal, and vomiting was rare and not continued.

Two laboratory tests were found to be of great diagnostic value: a leucocyte count of the blood and the examination of the cerebro-spinal fluid. There was invariably a distinct leucocytosis, even early, in all cases of cerebro-spinal fever; while in influenza a leucopenia or normal count proved the rule. A total leucocyte count was performed as a routine in all cases of pyrexia or suspected cerebro-spinal fever. If the blood count showed the presence of more than 13,000 leucocytes per c.mm., without any clinical condition to account for the leucocytosis, a lumbar puncture was performed; the naked-eye appearance of the cerebro-spinal fluid was often sufficient to clinch the diagnosis without awaiting the result of cytological or cultural examination. On the other hand, if the total white cell count was normal or showed a leucopenia, and there was no definite clinical evidence to suggest meningitis, the patient was watched, and a further count done on the following day, unless the symptoms pointed to the need for earlier intervention: the continued absence of a leucocytosis was a contra-indication of cerebro-spinal fever. In all doubtful cases lumbar puncture was performed. The cerebro-spinal fluid, at times even from fulminating cases of meningitis, appeared clear to the naked eye at the first puncture, but examination in the laboratory showed an increased cell count (60 or more polymorphs per c.mm.), together with an increased albumin content (0.1 to 0.4 per cent. or more) and frequently meningococci in the direct smears, certainly in culture during the next twenty-four to forty-eight hours. Cases of meningismus had clear, sterile cerebro-spinal fluid, with low cell count (about 10 cells per c.mm.) and a practically normal albumin content (0.03 to 0.05 per cent.).

No case was diagnosed as cerebro-spinal meningitis unless the specific organism was seen in, or isolated from, the cerebro-spinal fluid.

FULMINATING CEREBRO-SPINAL FEVER

The twelve cases of cerebro-spinal fever which form the basis of this paper were of the fulminating or malignant type. It might be argued that these were not all fulminating cases, as the patients did not die within three days, but it is maintained that they probably would have done so had it not been for the treatment given to them. The general description of the cases should dispel doubt on this point.

Etiology

The occurrence of cerebro-spinal fever in the recent R.A.F. outbreak was confined to newly joined recruits who were apparently in robust health. The average length of service was ten weeks, and the age incidence varied between 18 and 23½ years, the average age thus being 19¾. In four out of the twelve cases there was a history of influenza commencing five to ten days prior to the onset of the meningitis.

Meningococcus Type I, so far as could be ascertained with the high titre agglutination serums available, was isolated from the cerebro-spinal fluid in every instance. In one of the fatal cases *B. influenzae* Pfeiffer was also present in the cerebro-spinal fluid.

Strains of the meningococcus isolated were forwarded to the Ministry of Health Laboratory and to the Lister Institute in connexion with the preparation of a new anti-meningococcus serum.

Clinical Picture

Onset was always abrupt. The earliest symptoms were severe headache and repeated vomiting, often in the absence of pyrexia. Lumbar puncture, when performed at this stage, usually revealed a clear cerebro-spinal fluid containing 30 to 60 leucocytes per c.mm. Within six to eight hours the fluid became opalescent and showed a cellular content of 10,000 to 15,000 leucocytes per c.mm., also a high albumin content, even in cases where serum was *not administered during the first puncture*. At the same time there was marked exacerbation of the clinical symptoms—the temperature rose to 102° to 105°, there was violent delirium, followed rapidly by coma and accompanied by generalized petechiae. Head retraction was marked, and breathing became of the Cheyne-Stokes variety. The following notes bring out these points.

Case Illustrating Rapid Death

J. McK., aged 18 years 4 months (five weeks' service), reported sick at 9 a.m. on February 11th, 1931, complaining of headache, vomiting, and pains in back and legs; his temperature was normal. In the afternoon his temperature rose to 102°, he vomited several times, and became violent. Shortly afterwards he passed into coma. He was admitted to hospital at 8 p.m. in a deeply comatose condition, with stertorous breathing, pupils fixed in semi-dilatation, marked head retraction, Kernig's sign positive, knee-jerks and superficial abdominal reflexes absent, and generalized purpuric rash; temperature 102°; pulse rate 60; respirations 24. Lumbar puncture was performed at once and 60 c.cm. turbid fluid withdrawn—the cerebro-spinal fluid contained 15,000 leucocytes per c.mm., and meningococci were numerous. Antimeningococcus serum was administered—40 c.cm. intrathecally and 20 c.cm. intravenously. The clinical symptoms, however, gradually got worse, pulse rate and respirations increased (pulse rate 160, respirations 52), the patient became markedly cyanosed, and died suddenly at midnight, within fifteen hours of the onset of the disease.

Case Illustrating Average Recovery

H. W. P., aged 19 (two weeks' service), reported sick on February 7th, 1931, and was treated for influenza at his unit. The salient features of his illness were headache and backache, together with a moderate degree of pyrexia. The usual anti-pyretic remedies were given, and he had apparently recovered on February 12th. During the following night he had severe headache, and vomited several times. At noon on the 14th his temperature rose to 104.6°, and he became semi-comatose while being transported to hospital.

On admission he was comatose; temperature was 103.8°, pulse rate 104, and respiratory rate 36, breathing being stertorous. Pupils were dilated and scarcely reacted to light; eye-balls wandering. Knee-jerks were sluggish, and abdominal reflexes were absent. Kernig's sign was present, and neck muscles were spastic. A widespread petechial rash was present on trunk and limbs. A blood count showed a leucocytosis of 23,000 per c.mm., 91½ per cent. being polymorphs. Lumbar puncture was performed immediately, and 50 c.cm. turbid fluid were withdrawn under considerable pressure. The cerebro-spinal fluid contained 10,800 cells per c.mm. (97 per cent. were polymorph leucocytes), and showed the presence of many Gram-negative diplococci, which were chiefly extracellular. On culture, meningococcus Type I was isolated.

After draining off 40 c.cm. of the cerebro-spinal fluid, the subarachnoid space was irrigated with 160 c.cm. of normal saline. Then 20 c.cm. of concentrated globulin solution anti-meningococcus serum were injected intrathecally. Consciousness was partly regained soon afterwards.

Eight hours later lumbar puncture was repeated, and 60 c.cm. cerebro-spinal fluid were withdrawn. This was followed by saline irrigation, and the administration of 25 c.cm. antimeningococcus serum intrathecally and 20 c.cm. intravenously. The patient was now conscious, although cerebration was slow. Temperature was 104°, pulse rate 108, respirations 26. Spasm of neck muscles had greatly relaxed.

Lumbar puncture, the withdrawal of 40 to 60 c.cm. of cerebro-spinal fluid, followed by saline irrigation of the subarachnoid space, and the administration of 20 c.cm. of antimeningococcus serum intrathecally were carried out twice daily for the first four days of illness, and then once a day for the next six days—that is, four days after the meningococcus was last isolated from the cerebro-spinal fluid. Anti-serum was also given intravenously (10 to 20 c.cm. daily) for the first four days of the disease to counteract the septicaemia.

Under this treatment the patient's temperature for the first two days oscillated between 104° and 99°, the pulse rate remained relatively low (70 to 90), and the respiratory rate was 28. From the third to eleventh day of the disease the temperature varied daily between 100° and normal, pulse rate was 80 to 90, respiratory rate was 20 to 28. On the tenth day of illness the temperature was 100°, there was a well-developed and generalized serum rash, and the larger joints ached. Adrenaline (1 in 1,000) was given subcutaneously in 1/2 c.cm. doses at four-hour intervals, but there was no amelioration of symptoms. The following day 0.125 gram contramine was injected intramuscularly; improvement occurred quickly, and the rash disappeared completely in twenty-four hours. Progress thereafter was uneventful, the patient being allowed up a fortnight later.

This case illustrates the rapid onset of the septicaemic type of cerebro-spinal fever, and the method of treating this condition by means of intrathecal lavage with saline prior to the injection of antimeningococcus serum; also the apparent influence of contramine on the late serum manifestations.

Case Illustrating Slow Recovery and Complications

C. L., aged 23 (eight weeks' service), complained on January 5th, 1931, of severe headache, pains in limbs, and sore throat. Tongue was furred, and temperature was 101°. The following morning he had a rigor; headache was worse, there was vomiting, rigidity of neck, a positive Kernig sign, and extensive purpuric eruption over trunk and limbs. He rapidly became stuporose. Lumbar puncture was performed, and the cerebro-spinal fluid was found to be under pressure and very turbid. Laboratory examination of the fluid showed a cell count of 12,800 leucocytes per c.mm., 96 per cent. of these being polymorphs, a protein content of 0.9 per cent., and the presence of numerous meningococci, both extracellular and intracellular; cultures and serological tests proved the organism to be meningococcus Type I.

For the first four days the patient was lumbar-punctured twice daily, and once a day during the next six days. Only 20 to 30 c.cm. of cerebro-spinal fluid were removed at each puncture, and then 10 to 20 c.cm. of antimeningococcus serum (globulin solution) were given intrathecally without any previous saline irrigation. In addition, small doses of the serum (10 to 20 c.cm.) were given intravenously and intramuscularly each day. In all, 160 c.cm. of cerebro-spinal fluid were removed, and 125 c.cm. of antimeningococcus serum given intrathecally, 120 c.cm. intramuscularly, and 50 c.cm. intravenously.

During this time the patient had been extremely weak, often so delirious and violent that sedatives were much required. *But by the eleventh day of the disease* (January 16th) the meningeal symptoms were almost *nil*, and the meningococcus had disappeared from the cerebro-spinal fluid. The temperature, however, was raised, and ranged between 99° and 102° for the first three weeks of the illness, the pulse rate varied between 80 and 120, and the respiratory rate between 20 and 30.

The following complications arose: suppurative arthritis of the left knee commenced on the ninth day of illness and took two weeks to subside; acute orchitis (left) began on the twelfth day of disease and resolved in ten days; acute nephritis manifested itself on the twelfth day but cleared up within three weeks; otitis media, both ears, was first noticed on the seventeenth day of illness, and persisted for ten weeks.

This case illustrates the slow recovery of a patient treated by the withdrawal of small quantities of cerebro-spinal fluid and the administration of relatively small doses of antiserum.*

The Leucocyte Count of the Blood

The total leucocyte count of the blood was increased very early in the disease to 14,000 or more per c.mm., and in the next twelve to twenty-four hours it increased rapidly to 20,000 to 40,000 per c.mm., depending on the severity of the case. After the second day, in favourable cases, the count fell rapidly to 12,000 to 15,000 per c.mm., and remained about this level for the next fortnight (see Table III). In unfavourable cases there was usually an increase in the leucocytes up to 30,000 to 50,000 per c.mm. during the second day, and thereafter there was no tendency to fall. A persistently high leucocytosis was found to coincide with a thickening and holding up of the cerebro-spinal fluid. The total white cell count proved in many instances to be a valuable aid in deciding whether further lumbar puncture was necessary.

The differential leucocyte count showed usually that 90 to 96 per cent. of the total white cells were of the polymorph variety. The Arneth index during the first four days of the disease read somewhat as follows: 5:50:30:10:5. The differential count was therefore of little clinical value.

The Cerebro-spinal Fluid

The most important characteristics of the cerebro-spinal fluid, as regards diagnosis, were the naked-eye appearance, the leucocyte and protein content, and the presence or absence of meningococci.

The naked-eye appearance and cellular content of the fluid ran parallel; thus the greater the cell content, the more opalescent was the fluid. In favourable cases the fluid became more opalescent and the leucocyte count rose for twenty-four to forty-eight hours (to 20,000 or 40,000 cells per c.mm.) after the first administration of serum intrathecally, but the following day the opalescence diminished distinctly and the cell count fell rapidly to less than 10,000 per c.mm., and the figure gradually became lower daily (see Table III). In some unfavourable cases, the cerebro-spinal fluid was only slightly opalescent, but contained extracellular cocci in large numbers; in others the fluid became and remained like thick cream, while the cell content rose and remained at a high figure—50,000 or even 90,000 leucocytes per c.mm. This thick fluid tended to stagnate in the subarachnoid space, and thus complicated intrathecal medication. A differential count of the leucocytes in the cerebro-spinal fluid of these cases showed that 90 to 97 per cent. were usually of the polymorph variety.

The protein content was invariably high, ranging between 0.4 and 1.2 per cent. Even at the beginning of the disease, when the fluid was clear and the cell count was low, the protein content was found to be about 0.5 per cent., and this increased rapidly during the next twelve hours. The protein figure, prior to intrathecal serum injection, was in direct proportion to the severity of the disease; the higher the protein content, the more grave was the prognosis.

Meningococci were found in smears made from the deposit of the cerebro-spinal fluid that was withdrawn at the first puncture in every instance. At times they were very numerous, extracellular and intracellular cocci being present in every microscopical field. On other occasions they were so scanty that they were found only after prolonged search, and then they were usually extracellular: culture verified their identity. A rough estimate was made each day of the proportion of extracellular to intracellular cocci, and the finding confirmed Horder's statement referring to the intracellular position of the meningococcus—"The more marked this is, the better the outlook, and vice versa."[3] The correctness of this observation was striking in two instances in which the cocci tended to remain extracellular, and yet the patients appeared to be doing well clinically; both these cases terminated abruptly in death.

The meningococcus was readily obtained in pure culture from the cerebro-spinal fluid, even of patients under serum treatment up to the fifth to tenth day, depending on the case. The routine procedure was to incubate the fluid as withdrawn for six to eight hours at 37° C., subculture heavily from the deposit on to blood agar slopes previously warmed to body temperature, and to incubate these at 37° C. for one to two days.

The mortality rate was 50 per cent. There were 12 cases, 6 of which ended fatally; all the deaths occurred by the fifth day of disease. This rate compares favourably with that recorded by most observers for the fulminating type of cerebro-spinal fever.

TABLE III.—*Tabular record of a severe case of cerebro-spinal fever ending in speedy recovery. This indicates the more important clinical facts that should be recorded during the treatment of a case of cerebro-spinal fever.*

* These cases of cerebro-spinal fever were treated at the R.A.F. Infectious Diseases Hospital, Halton.

Treatment

Treatment was carried out at first along lines that had been found beneficial when dealing with previous cases of cerebro-spinal fever; antimeningococcus serum was the sheet-anchor. Unfortunately, in the recent epidemic, the meningococcus causing the infection was Type I, whereas the bulk of the therapeutic serum available in this country was made chiefly for use against Type II of the organism. It soon became evident that the antimeningococcus serum was not to be relied upon to the same extent as formerly, so that certain details of treatment that were considered previously to be of secondary importance now took pride of place. Particular attention was paid, therefore, to the adequate relief of pressure within the subarachnoid space in order to lessen its injurious effects on the nerve centres, especially those in the medulla; also to efficient irrigation of the subarachnoid space to help to remove the pus and meningococci and to aid in the circulation of the antimeningococcus serum. The question was whether the subarachnoid space should be irrigated by means of saline as advocated by Hirsch,[4] and Aubertin and Chabanier,[5] or by promoting the secretion of cerebro-spinal fluid and increasing the intrathecal pressure by means of a general anaesthetic, as recommended by Flack.[2] After experience with both methods, the use of saline irrigation was deemed the more suitable, as this conserved the body fluids and cast no unnecessary strain upon the respiratory organs, already the seat of inflammation in most cases; in addition, the sensations of the conscious patient served as guides for both the amount and rate of fluid required to be withdrawn and injected. In two instances there was a local blockage in the subarachnoid space of such degree that after the third day of disease little fluid could be withdrawn by lumbar puncture; a general anaesthetic (ether) was given for three-quarters of an hour, the needle being left in position, and yet no more fluid could be obtained. Cistern puncture confirmed the theory of local blockage of the subarachnoid space, for the cell content of the fluid obtained by cistern puncture was roughly one hundred times less than that obtained by lumbar puncture. In such cases as these it was felt that general anaesthesia might do more harm than good.

The following routine treatment was found to give the most satisfactory results, and was adopted eventually for all definite cases of cerebro-spinal fever.

Immediately on admission to the ward 1/4 grain of morphine was given hypodermically as a sedative, and 5 c.cm. of antimeningococcus serum were injected intramuscularly into the flank to act as a desensitizing dose. By the time that the patient was cleaned (fifteen to twenty minutes) hypnosis was sufficient to permit the lumbar puncture to be undertaken. About 1/2 c.cm. of 5 per cent. novocain solution was injected intradermally over the site chosen for the lumbar puncture, usually the third interspace, and after re-washing the hands the operator made his puncture. The cerebro-spinal fluid was allowed to flow so long as it was under distinct pressure, 40 to 60 c.cm. being always drawn off, more if necessary; in some instances up to 90 c.cm. of fluid were removed with ease. In cases where the flow tended to be very rapid, the stylet was pushed partly home to lessen the rate of flow, and so more gradually lower the intracranial pressure. Relief of fluid usually made comatose patients pass into irritability, less marked when under the action of morphine; judicious handling by attendants controlled this excitability. During the above procedure 200 c.cm. of sterile normal saline were warmed to 37° C. This saline was used to irrigate the subarachnoid space. A 20 c.cm. syringe was filled with the saline and connected directly to the lumbar puncture needle, and the salt solution was injected slowly—about four to five minutes being allowed for the 20 c.cm. The stylet was inserted and the foot of the bed raised on blocks for a few minutes, then lowered, the stylet removed, and the saline allowed to drain off into a measure glass. This process was repeated until 100 to 200 c.cm. of saline were used and the washings came away fairly clear; great care was taken throughout to see that at least as much fluid was drawn off as went in. The last washing usually consisted of a mixture of 10 c.cm. saline and 10 c.cm. antiserum. The antimeningococcus serum (globulin solution), warmed to body heat, and well shaken so as to include the deposit, the most potent portion of the serum, was then injected slowly by means of the syringe. The dosage was 20 to 40 c.cm., depending on the amount of fluid withdrawn; it was found expedient to inject considerably less serum than the amount of cerebro-spinal fluid removed, otherwise symptoms of increased intrathecal pressure manifested themselves within a few hours. Thus, if 60 c.cm. of cerebro-spinal fluid were obtained, not more than 30 c.cm. of serum were injected intrathecally. The foot of the bed was raised during the administration of the serum, and kept raised for at least two hours afterwards to facilitate gravitation of the serum towards the brain. Finally, 10 c.cm. of antimeningococcus serum were injected intravenously to counteract the septicaemia which was a prominent feature of these cases.

This procedure of lumbar puncture, saline irrigation of the subarachnoid space, and intrathecal injection of antiserum was repeated within eight hours, then given twice daily until the fourth or fifth day, and once daily for at least the next five days. The intravenous administration of serum was practised daily for the first three days only, unless the septicaemic symptoms persisted beyond that time. For two hours prior to each lumbar puncture the head of the bed was raised on blocks to aid in the gravitation of the cerebro-spinal fluid towards the lumbar region and to facilitate the withdrawal of at least 40 c.cm. of the fluid.

Calcium lactate, 10 grains, was given by the mouth thrice daily from the beginning of the treatment to try to prevent serum sickness. Contramine was given intramuscularly in a 0.125 gram dose to those patients with serum rashes; relief followed quickly, but if necessary the dose was repeated after twelve hours.

The above synopsis of treatment is given in the hope that it may be of some service to others, and to awaken constructive criticism. It may be objected that the number of cases treated was insufficient upon which to form an opinion. The number of cases was certainly few, but it should be borne in mind that although various methods of treatment were tried on several of the patients—serum of different brands in small doses, large doses, intravenously, intrathecally, combined, and so on—it was only when saline irrigation was added to the treatment that distinct improvement followed. All those engaged in treating the cases were impressed by the beneficial effects of the irrigation: there was less tendency for the cerebro-spinal fluid to thicken unduly; coma, delirium, and toxaemia disappeared rapidly; and recovery was accelerated. For an example see Case H. W. P. recorded above, also Table III. Of the six patients treated by saline irrigation, four made a safe recovery, or, in other words, the death rate was 33 per cent.; this compares favourably with the death rate of other observers when only cases of fulminating cerebro-spinal fever are considered.

Control of the Disease

General prophylactic measures applicable to the control of diseases spread by droplet infection were adopted as soon as the epidemic nature of the disease was recognized.[6] These measures, as indicated in the beginning of this paper under the headings of history, origin, and spread of the infection, included the search for, and isolation of, contact carriers; special supervision in the spacing of beds and the efficient ventilation of barrack rooms; closure of canteen, cinema, and other places of indoor entertainment; and the disinfection of the nasopharynges of all personnel by means of nasal douches or sprays. The efficacy of this policy was shown by the prompt termination of the epidemic within forty-eight hours of its adoption. The operation of these measures, however,

interfered greatly with the daily work of the personnel concerned, and threw a lot of extra labour on certain departments and individuals; as the need for some of these precautions was problematic, the opportunity was taken to make observations regarding their relative values for future guidance.

The search for and isolation of carriers was extended to include all the recruits and the members of the permanent staff who came into close contact with them. Wholesale swabbing of the nasopharynges of these individuals showed that carriers of the meningococcus were distributed fairly uniformly throughout all the barrack rooms—a fact that could have been prophesied in advance. The percentage of persons carrying was found to be as high as 32 at one time. This was only a relative figure for the technique used, because, with a more perfect technique and more frequent swabbings, probably many more individuals would have been found to harbour some meningococci. The fact remains that the general swabbing helped to detect the more heavily infected carriers, who were potent sources of further infection.

Prompt isolation limited their sphere of action, and this undoubtedly aided in stemming the epidemic. The isolation of all detected carriers was complete; this was considered advisable, for though simple spacing out would have limited their range of activity, the adequate supervision of scattered carriers would have been impracticable.

The spacing out of beds and efficient ventilation of barrack rooms, as normally arranged by the authorities in charge, was adequate, there being 2½ to 3 feet between adjacent beds, so that this was not a likely factor in the spread of the infection. The inter-bed space was increased, however, to 4 feet, and, as a further precaution, the beds in each row were placed alternately head and foot towards the wall. But the problem of preventing local crowding around the fireplaces remained; this was difficult to control without constant supervision.

The canteen and cinema, well-recognized spots for local overcrowding, lived up to their reputation, especially the former. Reference to Chart 2 and the associated text supplies all the information needed on this subject. The canteen was closed on February 12th, and as a temporary measure the salespeople were permitted, at appointed times, to serve the men in the barrack rooms. The closure of the canteen proved a crucial measure in staying the epidemic.

Nasopharyngeal disinfection was applied to all personnel in the infected unit, first of all by means of a spraying chamber, latterly by nasal douching and gargling. Zinc sulphate (1 per cent. solution) was used in conjunction with Levick's steam spray, and the men were exposed to its action for fifteen minutes daily. Nasopharyngeal swabbings taken from a hundred men the day following their sixth spray treatment showed 32 per cent. to be harbouring viable meningococci—the highest carrier rate detected during the epidemic. It was suggested that this proved the efficacy of spraying, for the coryza induced by its action caused lurking germs to be discharged from their lairs in the nasal sinuses. The use of the spray chamber was discontinued, however, partly on account of the length of time necessary to pass all the personnel through it, and in part because of the danger of spreading infection when the men crowded together during the various stages of coming, going, and entering the chamber. Latterly, nasal douching was adopted instead of the spraying. The douching was carried out thrice daily for a fortnight with either a 1 in 5,000 solution of potassium permanganate or an alkaline douche which consisted of sodium bicarbonate and borax, 2 drachms of each, liquid carbolic acid, 1 drachm, sugar, 1/2 ounce, water to one pint. The solution was held in the palm of the hand and sniffed up vigorously. In addition, a chlorine gargle was given according to the following formula: potassium chlorate, 200 grains, hydrochloric acid, 40 minims, to a pint of water. This method of nasopharyngeal disinfection proved simple to administer and efficient as regards its action, as may be judged by the result obtained in the treatment of carriers.

The Treatment of Carriers.—The contact carriers were transferred to special isolation blocks at Halton, where routine treatment was carried out. They were exercised in the open and spaced out as much as possible, and thrice daily for a fortnight they practised nasopharyngeal disinfection by douching and gargling, as indicated above. At the end of a fortnight medication ceased, and nasopharyngeal swabbings were examined for the meningococcus every other day. In any case where meningococci were found to persist, treatment began all over again. Carriers were not pronounced free from infection until six consecutive swabbings proved negative to the meningococcus; 75 per cent. were found to be free from the infection within a month. For fuller details see Table I.

Conclusions

1. The recent outbreak of cerebro-spinal fever in the Royal Air Force was confined to newly joined recruits, aged between 18 and 23½ years, and appears to have been precipitated by local overcrowding in canteen, cinema, and around barrack room fires.

2. It was not an isolated outbreak, but formed part of an epidemic spread widely over England, and the lessons learned from it can be applied to the problem as it affects the civil community, among which the incidence of this disease has of late years grown to disquieting proportions. It is suggested that the increased patronage throughout the country of cinemas with their continuous performances, cafés in preference to bars, and closed charabancs in lieu of trains play an important part in the dissemination of droplet infections, and may help to explain the increased incidence of cerebro-spinal fever.

3. The control of the disease is chiefly a matter of spacing out, so that special attention should be paid to the number of individuals gathered at one time in canteens, cafés, cinemas, and closed conveyances. The proprietors and public should be suitably warned of the danger of confined atmospheres. Barrack rooms in this country should be centrally heated to ensure efficient warmth and ventilation, without local overcrowding.

4. Nasopharyngeal disinfection by means of simple douching and gargling is efficient, and should be adopted as an additional precautionary measure, especially by those who come in contact with the sick, and by carriers. It should be persisted in for a fortnight after the last exposure to infection.

5. A general nasopharyngeal swabbing of the inmates of an infected barracks is an advisable measure, as it is a rapid method of detecting the more heavily infected and therefore dangerous carriers. Prompt action in this direction, together with adequate spacing out of personnel, should nip in the bud most epidemics of cerebro-spinal fever. Swabbing of the immediate contacts should suffice, if further cases arise.

6. Detected carriers should be isolated to limit their radius of infectivity. They should practise nasopharyngeal disinfection by douching thrice daily for at least a fortnight before swabbings are examined for the meningococcus. No carrier should be liberated unless at least six swabbings, taken on alternate days, are negative to the meningococcus. Alternatively, all carriers might be liberated at the end of six weeks without the examination of nasopharyngeal swabbings, provided they had carried out the nasopharyngeal disinfection daily during that period.

7. Early diagnosis is most important both for the sake of prevention and of cure. Most cases can be diagnosed by careful clinical examination, but a simple total leucocyte count of the blood is of material aid in the differential diagnosis between influenza and the early stages of cerebro-spinal fever.

8. The globulin content of the cerebro-spinal fluid and the position of the meningococci, whether chiefly intracellular or extracellular, are valuable prognostic guides.

9. There is a tendency to regard antimeningococcus serum as a magic cure for cerebro-spinal fever, but, although some batches of the serum have been possessed of remarkable curative powers, others have proved of little therapeutic value. This variability of potency has been noted in many epidemics, and it would appear to be due to difference in the technique of preparing the serum, also to the nature and proportion of the types of meningococci used. Thus, the recent epidemic has been caused by Type I meningococcus, whereas the polyvalent antimeningococcus serum available has been prepared chiefly against Type II of the organism. In addition, the success of the treatment depends greatly on applied physiology. The aim should be to reduce the increased intrathecal pressure to normal limits, to replace as far as practicable the purulent cerebro-spinal fluid by a bland fluid such as normal saline, and to ensure the uniform distribution of antiserum throughout the subarachnoid space. For this purpose about 60 c.cm. of cerebro-spinal fluid should be withdrawn, the subarachnoid space irrigated with 100 to 200 c.cm. of saline, and up to 30 c.cm. of antimeningococcus serum injected intrathecally, once or twice daily, until at least three days after meningococci have disappeared from the cerebro-spinal fluid. This treatment by subarachnoid lavage is not new : it is apt to be ignored, however, possibly because of the extra work entailed; but this is labour well spent, as those who care to try it will be able to testify.

SPONDYLITIS DEFORMANS

BY

CHARLES W. BUCKLEY, M.D., M.R.C.P.

PHYSICIAN TO THE DEVONSHIRE HOSPITAL FOR RHEUMATIC DISEASES, BUXTON

(With Special Plate)

This paper is based upon a clinical and radiological study of 150 cases of spondylitis of various types treated in the Devonshire Hospital during the last three years. In order to narrow down the scope all cases in which there were no obvious bony changes on *x*-ray examination, in spite of stiffness of the back, have been excluded, as well as cases of osteitis deformans.

The most notable investigations prior to the general use of *x* rays in diagnosis are those of Pierre Marie, Strümpell, and von Bechterew, with whose names certain types of spondylitis have come to be associated. It is, however, worthy of note that Dr. Bernard Connor, writing in the *Philosophical Transactions* in 1700, describes a skeleton [illegible] ying the characters of spondylitis ankylopoietica with an exactitude that can hardly be improved upon, and deduces the clinical features of the disease.

" All these bones which naturally are separate and distinct from one another were here so straightly and intimately joyned, their ligaments perfectly bony and their articulations so effaced, they readily made but one uniform and continuous bone, so that it was as easie to break one of the vertebrae in two as to disjoynt or separate it from the other vertebrae or the os sacrum from those of the ilia. The roots of the ribs made but one equal smooth and plain superficies with the vertebrae and their apophyses. . . . The cartilaginous edge of the vertebrae themselves were turned to perfect bone. But when I had sawed two of the vertebrae asunder at the commissure I found that this uniting did not enter above two lines deep . . . their middles were separated as they usually are, and touched each other only at their edge which was raised up a little above the middle part."

It is also clear from other parts of his description and from the illustration he gives that there were no osteophytes, and that the ankylosis was due to ligamentous ossification. Hilton Fagge in 1877[2] described a similar case which came to necropsy, but adds the observation that there was great softening and fragility of the bones (a point of much importance also stressed by Leri[3]), which is a characteristic feature of this form, the " spondylose rhizomelique " of Marie and Strümpell. The type described by von Bechterew differs from that of Strümpell and Marie. Fraenkel[4] contrasts the two types as follows:

Bechterew Type	*Marie-Strümpell Type*
Stiffening of the spine from above downwards, descending.	Stiffening of the spine from below upwards.
The ankylosis results in a very bent attitude; kyphosis is always present.	The ankylosis results in an erect attitude; kyphosis is seldom seen.
Nerve-root symptoms and irritation phenomena are always present.	Nerve manifestations may be missing in some cases.
Joints of the extremities are never involved.	The root joints of the extremities are always, and other small joints often, ankylosed.
Paretic condition of the muscles with slight atrophy.	Atrophy of the musculature is often very pronounced.
Process begins as an infection of the pia spinalis.	Primary process is an ossification of the spine.
Etiology: heredity, trauma, lues.	Etiology: rheumatism and infection.

The first five of these points of difference are not diagnostic, but appear to depend on the degree of severity, on the treatment of the case, and on the site at which the disease begins. The commencement as an affection of the spinal meninges is the essential difference, but much more evidence is required before it is proved that the two types are distinct. I am therefore adopting the classification of spondylitis into two main groups: spondylitis ankylopoietica or ankylosing spondylitis, which includes both the above varieties, and spondylitis osteo-arthritica, the degenerative or hypertrophic form, one of the outstanding features of which was indicated by Sir Samuel Wilks in the name which he gave it—" labourer's spine." To these may be added traumatic, tuberculous, and possibly syphilitic spondylitis.

SPONDYLITIS ANKYLOPOIETICA

As the name implies this is distinguished by its striking tendency to ankylosis of the vertebral and adjoining articulations, the end-result of which is so vividly described by Connor. Of my series sixty were of this type, and the age incidence was as follows:

Below 20	20-30	30-40	40-50	50-60	Over 60
1	17	20	15	5	2

There were six women in the series, which, so far as I am aware, is a higher proportion than has previously been

recorded. This is in marked contrast with the sex incidence of rheumatoid arthritis. The Devonshire Hospital figures for the past three years are 1,137 males and 1,991 females, figures which, while less striking than some of the statistics quoted, demonstrate the much greater susceptibility of the female sex. This marked difference in sex incidence is difficult to explain if the view is accepted that spondylitis ankylopoietica is only a form of infective arthritis in which the spinal articulations rather than those of the extremities happen to be affected. Freund,[5] without giving actual figures for comparison, states that he has seen only one female among the numerous cases he has observed, and can trace only one other in the literature. The latter patient, whom he describes, presented very definite indications of thyroid and ovarian functional deficiency, and developed symptoms a year after an attack of typhoid fever. The six female cases in my series conform closely to the classical types, two showing the von Bechterew characteristics, though not in a pronounced form; it is therefore desirable to tabulate them for purposes of comparison.

Case	Age	Duration	Symptoms	X-Ray Findings	Cause	Menstruation	General Health
J. C.	25, S.	4 years	Stiffness and pain in back	Osteoporosis; no exostoses; linking of vertebrae	Frequent sore throats	Normal	Good
C. H.	36, M.	5 years	Pain first in left leg, spreading to back; stiffness	Osteoporosis; no exostoses; ankylosis of vertebrae, of sacro-iliac and hip-joints	Probably gonorrhoea	Irregular, excessive; no children	Poor; emaciated weight 5st. 10lb.
L. L.	49, M.	7 years	Began in lumbar region and spread up to neck	Osteoporosis; no exostoses; ankylosis of whole of spine	Probably gonorrhoea	Menopause at 47; no children	Good
E. H.	31, M.	4 years	Pain and stiffness of back	Osteoporosis; no exostoses; ossification of ligaments and early sign in disks	Onset after parturition	One child; no note of uterine functions	Normal
M. P.	38, S.	5 years	Pain began in neck and spread downwards; kyphosis at cervico-dorsal junction	Increased density of bones except sacrum; disks thin; ankylosis of vertebrae, costo-vertebral, sacro-iliac, and hip-joints; no exostoses	Onset after influenza; query syphilis	Normal	Very thin; weight 6st. 3lb.
E. Y.	25, S.	4 years	Head bent forward, due to kyphosis at cervico-dorsal junction; spine rigid	Ankylosis of upper dorsal vertebrae; density normal; no exostoses	Query syphilis; negative Wassermann	Normal	Blood pressure 190 130

ETIOLOGY

No case in this group resembles the one described by Freund, nor is there evidence of any definite endocrine disorder. The first case appears to have been due to infection from the throat; the second, third, and fourth are probably gonorrhoeal, the four being of the Marie-Strümpell type. The last two resemble the form described by Bechterew in the fact that the disease began in the cervical region and spread downwards, giving rise to kyphosis at the cervico-dorsal junction and to the resulting peculiar carriage of the head. They did not present any symptoms indicative of involvement of the nerve roots; one showed increased density of bone; and the other was normal as far down as the sacrum, which appeared rarefied. Syphilis is mentioned as one of the possible causes of this type, and the marked increase of density in the case of M. P. supports this opinion, but no Wassermann test was made; E. Y. showed a negative reaction to this test, but an abnormally high blood pressure. It is open to doubt whether a single negative result is conclusive, and Schlesinger[6] states that the Wassermann reaction can be positive in the joint fluids when it is negative in the blood.

INJURY AND INFECTION

In diseases of this kind the information supplied by the patient as to the probable cause is never very reliable, and while some sort of history was obtained in forty-five cases, too much importance must not be attached to it. There was a clear history of accident in seven cases (apart from those with definite injury to the spine which have been classed separately); eight others referred the onset to their service during the war. Much importance was formerly attributed to injury as a cause of spondylitis, but this view is now losing ground. Marie and Astie[7] regard injury as having a neurotrophic influence, impaired nutrition of the vertebrae being secondary to concussion of the spinal cord; but, on the other hand, Poncet and Leriche[8] hold that the effect of the injury is merely to favour infection, and the frequency with which tubercle attacks the spine after accident supports this view. Four patients gave a history of enteric fever; of these, one had a positive Widal reaction and another, whose reaction was negative, had recently had phlebitis, possibly of typhoid origin. Five gave a history of onset with acute generalized rheumatism or a previous attack of rheumatic fever, though it is possible that some of these may have been cases of gonorrhoeal rheumatism. Ten admitted having had gonorrhoea or showed definite evidence of it, and probably many more had been infected; but it is difficult to induce patients to be frank on this point. Of the remainder, ten had septic tonsils or pyorrhoea, and several had had their teeth extracted at some date before admission, but after the onset of the symptoms, which suggests that they were infected. I think that all that can be deduced from these figures is that injury or strain and previous attacks of rheumatism are important predisposing causes, and that infection is the actual exciting cause—gonorrhoea, pyorrhoea, or infected tonsils being the most usual. I am not fully convinced that the *Bacillus typhosus* causes typical spondylitis ankylopoietica.

Sedimentation Rate

In twenty-three cases the sedimentation rate varied from 44 to 65, with a mean of 52 at the end of the first hour, compared with the normal of 90 to 95; this supports the infective theory, and is in marked contrast to the rate found in nine cases of spondylitis osteo-arthritica which varied from 84 to 94, with a mean of 88.

Symptoms and Radiographic Appearances

On radiographic examination the most striking feature in a large proportion of the cases was osteoporosis of the vertebral bodies and often of the ilia and sacrum; it was frequently of extreme degree. This is a point of much importance, confirming Fagge's observation of the great softening and fragility of the bones in his case at necropsy, and furnishes an explanation of some of the features of the disease. It is the primary change preceding any alteration in the ligaments, so far as I can judge. The effect varies in the different parts of the column according to the form and degree of the curvature, and also depends on whether the patient has been kept in bed or has mainly been in an erect or sitting posture. If the disease starts in the lumbar region there is pain in the back, and as lying is the most restful posture it is adopted as much as possible, especially in acute cases. Very commonly

there is also pain in the distribution of one or both sciatic nerves due to pressure on the nerve roots as they pass through the spinal foramina ; this is an additional reason for resting. The result is that flattening of the lumbar curve is commonly met with, and kyphosis does not occur.

Ossification

Inflammation of the joints between the articular processes arises early and leads to marked tenderness of the spine on pressure or percussion. Ossification of the capsules of these joints, of the ligamenta subflava, and of the interspinous ligaments, quickly follows, and the spine becomes rigid (Fig. 1). Ossification of the anterior common ligament is not a conspicuous change in this region in man, but is very frequently met with in horses. This has led to undue importance being attached to this change as a feature of the disease: it is simply a reaction to mechanical stress on the weakened bony structures which is obviously present to a great degree in horses in this part of the spine. Ossification of the intervertebral disks is the common change in man, affecting the outer fibrous laminae but not the central portion, which gives rise to an appearance suggesting an extension of the anterior common ligament round the sides of the bodies and its ossification. The bodies themselves tend to become constricted in the middle and spread at the edges with the appearance described by Krebs[9] as "bamboo-like" (Fig. 2) ; but exostoses do not form, and this is a most important diagnostic point. The articular processes become firmly ossified (often also the spinous processes), the bodies are joined together by the ossified disks and ligaments, and the spine becomes a rigid bar (Fig. 3).

When the dorsal region is affected either primarily or by the upward spread of the disease the changes are modified by the difference of the curve ; kyphosis develops early, but is never extreme, the posterior ligamentous structures ossify to meet the strain, and ossification often involves the anterior and posterior common ligaments. The costo-vertebral joints are implicated early and respiration soon becomes entirely abdominal ; intercostal pain is a common symptom ; and the ribs become firmly ossified to the vertebrae.

Lipping of the anterior edge of the bodies often occurs as a result of the pressure, which is naturally greatest on the concave aspect of the curve ; the greater the kyphosis the more marked will be the lipping. The disks become thinned and lenticular in shape, and union soon takes place at the edges of the bodies. When the lower cervical vertebrae are affected the weight of the head causes compression of the bodies, and an extreme degree of kyphosis is apt to develop. To compensate, the head is hyperextended and the bones become ankylosed in this position, characteristic of the Bechterew type (Fig. 4). The atlanto-axial joint often escapes, and thus rotation of the head is retained, but there is usually well-marked thickening and ossification of the anterior common ligament.

Ankylosis

The sacro-iliac joints become completely ankylosed early in the disease if it starts in the lower spine. The hip-joints quickly follow suit, and will be fixed in extension or flexion according to the position usually taken up by the patient. In one of my cases the body from the head to the knees was completely fixed, but there was no bony change in knees or shoulders. Another whose hips were fixed in semi-flexion has recently undergone operation in the hope of restoring their mobility. Although pain and some degree of stiffness may be met with in knees and shoulders, as well as in other peripheral joints, I have not met with the bony ankylosis in these joints recorded by other observers. It would seem as though bony ankylosis occurred only where immobilization was secured by any means and that treatment should be directed to preventing this.

The degree of softening is not so great as that met with in osteitis deformans, and never results in deformity of the kind or extent met with in that disease, though scoliosis may occur as well as kyphosis, and is more common in the lumbar region. It would seem a reasonable hypothesis that the softening of the vertebral bodies and the consequent danger to the vital structures in the spinal canal led to rapid ossification of the ligaments to neutralize this risk.

Freund[5] regards as the primary change a destructive inflammatory process in the joints of the articular processes leading to atrophy and ossification of the cartilage ; Fraenkel[4] also considers the ankylosis of these structures to be primary.

My own observations lead me to think that osteoporosis is earlier than any destructive process in the articulations which can be detected by x rays. The appearance of the hip-joints when the disease has spread to them indicates clearly that the cartilage undergoes destructive changes early ; later there is often slight mushrooming of the head of the femur, but not to anything like the same degree as in osteo-arthritis of these joints.

Progress of the Disease

The rate of progress of the disease varies widely. In some cases the onset is acute and the progress rapid, so that the whole spine becomes rigid within a few months. In others the rate is much slower, and may be arrested when only a portion of the spine has been affected. Sometimes the onset is so insidious that the patient does not seek advice until there is extensive damage. The earliest symptoms are commonly those of lumbago and sciatica, and may be of no great severity. It is not uncommon to meet with a history of such symptoms followed by remission and recurrence after a few months, this happening two or three times before the nature of the disease is recognized. Spondylitis ankylopoietica may supervene upon other diseases of the spinal column and cause difficulty in diagnosis. This sometimes occurs when the degenerative changes of "labourer's spine" have already set in ; in this way mixed cases arise.

The small joints of the limbs are not often affected. There were five cases in the series which showed arthritis of the hands, wrists, or ankles, but in these there was no difference in the appearance of the spine. One in fact furnished the best radiogram of ossification of the anterior spinal ligament in the dorsal region. In this patient the symptoms in the back appeared eight years before I saw him, and the knees and ankles had become affected much more recently ; he had been able to continue his work as a post-office sorter throughout. Since gonorrhoea and other causes of infective arthritis may set up either a spondylitis or an arthritis of the rheumatoid type, it would not be remarkable if both conditions occurred together. It is surprising that this is so rarely the case. On the whole I think that the balance of evidence is in favour of the view that the pathological basis is different in the two conditions, but that both may occur in the same individual. It is, however, extremely probable that further study may reveal features by which the cases I have grouped together under the general term spondylitis ankylopoietica may be divided into two or more subclasses. To attempt to do so at present would lead to confusion.

SPONDYLITIS OSTEO-ARTHRITICA

This disease is described by some writers as spondylosis deformans to emphasize its essentially degenerative character, but the ankylopoietic form is productive of greater deformity. The term osteo-arthritica, though

cumbersome, has the advantage of clearly defining the condition, which is of the same nature as osteo-arthritis of other joints. There were 61 patients of this type in the series, of whom only two were women. The age incidence was: 40 to 50 in 13 cases; 50 to 60 in 34 cases; and 60 to 70 in 14 cases.

Etiology

The most important factor in its production appears to be the strain and wear and tear of heavy labour. Of the 61 patients, 31 were coal miners, and a majority of the others were engaged in similar laborious work. I believe that if any substantial number of men over 50 engaged in such work were submitted to *x*-ray examination, a large proportion (probably not less than 50 per cent.) would show signs of spinal osteo-arthritis without having had any notable symptoms. My cases presented all grades, from slight lipping of the bodies of the vertebrae to the formation of very large exostoses which, in some, became joined to form bridges between adjacent vertebrae —a form of union which is quite different from that occurring in spondylitis ankylopoietica.

Symptoms

Frequently the patient says that the onset of pain and stiffness of the back has been quite sudden, whereas the radiograph reveals exotoses which must have been many months or years in process of formation. In reality the back has gradually been getting stiffer until some effort, no greater than has previously been borne with impunity, gives rise to pain of a more or less disabling character, and the patient seeks treatment. After a short rest he attempts to work again, with the same result; and he is forced to give up his usual occupation and seek something lighter, often without success. On the other hand, he may attribute his disability entirely to the sudden strain which brought it to light, and become a claimant for compensation; it is thus a matter of much medico-legal importance to recognize the sequence of events.

It is to be noted that spondylitis osteo-arthritica is not a seriously crippling disease, and the degree of flexibility of the spine which is retained is often remarkable. Some flattening of the lumbar curve is usual, and there may be kyphosis of the dorsal region which is not due to the spondylitis directly, but has gradually developed as a result of habitual posture, usually occupational, and become fixed by the bony changes. Pain is not a marked feature, except from strain or over-use, and may be entirely absent; but, on the other hand, it may be severe if the exostoses press upon the nerve trunks at their emergence from the column or at any point in their course, and it may then be referred to the extremities (Fig. 5).

The primary change is probably in the intervertebral disks, which, as a result of long-continued strain upon their buffering function, aided it may be by toxic or infective influences, undergo degeneration or partial atrophy just as does the cartilage of other joints in similar circumstances, of which the best example is the hip in malum coxae senile. As a result, exostoses are thrown out to support the weakened articulation. Local trauma (especially if frequently repeated, even though only slight) tends to marked local development of such changes. A striking example of this occurred in one of my cases which presented a slight kyphosis of the lumbar spine and exostoses of the second and third lumbar bodies. On inquiry, the patient, an intelligent man, volunteered the suggestion that it might be due to having to walk more than a mile from the bottom of the pit in which he worked along a seam too low for him to stand upright in order to reach his working place. In doing so he often bruised his back against the roof in just the position in which the changes were observed. A strain or injury may affect one side more than the other, or the habitual working posture may give rise to changes greater on one side, with a resulting scoliosis. Very large curved exostoses may be developed in this way.

Effect of Syphilis

It appears to me, however, that some additional factor, toxic or infective, is required to produce the more extreme examples. Syphilis is probably one of the most important of such influences, and may be suspected if the increase of density is very marked locally or generally; clear areas possibly due to gummata are also seen in the radiograms in some cases. A negative Wassermann reaction does not absolutely exclude syphilis; but on the other hand one meets with cases in which the Wassermann reaction is positive, but which do not show any changes in the vertebrae differing from those in the general run of cases. A curious chalky appearance is sometimes seen in the negative, which cannot be demonstrated in a print. The excessive and irregular osteophytic development is sometimes suggestive of Charcot's arthropathy. There were nine cases in the series in which there were changes suggestive of syphilis, but in only one was the Wassermann test positive, though it was not tried in all. In one there was a history of a chancre, another had signs of neurosyphilis, and the others showed advanced arterial degeneration. The evidence is not sound enough on which to base any description of a syphilitic spondylitis. The question of osteitis deformans was considered in some cases, but it was excluded by means of the phosphoric esterase test.

OTHER TYPES OF SPONDYLITIS

Healed or quiescent tuberculosis of the vertebrae may present an appearance which it is easy to confuse with other forms of spondylitis. It is not uncommon for several vertebrae to be affected and to present an appearance resembling the osteo-arthritic form. Jones and Levett[10] lay stress upon the perivertebral shadow seen in antero-posterior views; but in old cases this may be absent or difficult to identify. They also point out that an irregularity of the anterior edge or corner of the bodies as seen in a profile radiogram is characteristic (Fig. 6); this was readily demonstrated in some cases in this series. The intervertebral disks undergo rapid disintegration and disappear, leaving the eroded surfaces of the bodies in contact; fusion frequently takes place. In the lumbar region especially there may be an osteoplastic periostitis linking the bodies together, which may in turn be invaded by the disease.

Kümmell's Disease

Kümmell in 1895 described a condition to which he gave the name spondylitis traumatica. In this, after an injury to the back which appears to be quickly recovered from, the symptoms of pain and stiffness reappear and a slight kyphosis develops. This is due to the breaking down of the cancellous tissue of the body of the injured vertebra, which is crushed and becomes wedge-shaped. Its early recognition is important, to prevent the damage from increasing. There were two cases of this condition in my series, in addition to simple crush fractures and fractured transverse processes, both of which may closely simulate spondylitis clinically, since rigidity, pain, and tenderness are prominent symptoms; but they are readily diagnosed in a radiogram. Malignant disease may occasionally give rise to difficulty, but, since it is usually secondary, attention to the history should serve to prevent mistakes. The condition may resemble tuberculous disease very closely. There were two cases of this kind in the series, and in one the secondary growth had developed in the presence of typical spondylitis osteo-arthritica.

NOTE ON TREATMENT

The question of treatment is outside the scope of the present paper, and would take up too much space. The essential point is to recognize the ankylopoietic form as early as possible and to deal with any focus of infection, to take steps to prevent the development of kyphosis, ankylosis of the hips, etc., by rest, supports, or by other methods, and to pay special attention to the defective calcium metabolism by correcting vitamin deficiency and other disorders of nutrition. Freund recommends treatment at a spa, preferring Gastein, a spa of a type well represented in this country.

I wish to express my thanks to my colleagues on the staff of the Devonshire Hospital for permission to make use of some of their cases, to Mr. J. Race of the research department for much help in translating references in German literature, and to Mr. Gibson, the radiographer, for his excellent illustrations.

TWO CASES OF SYPHILITIC SPONDYLITIS

BY

CHRISTINE ABERNETHY, M.B., CH.B.

ASSISTANT RESIDENT MEDICAL OFFICER, FAZAKERLEY SANATORIUM, LIVERPOOL

Syphilitic spondylitis is an uncommon lesion according to the literature, and, for this reason, two such cases admitted to Fazakerley Sanatorium seem worthy of record.

CASE I

Male, aged 36, gave a history of "rheumatism" of ten years' duration affecting his arms and shoulders, and improving and relapsing at intervals. Twelve months before admission he was crushed between heavy gates, and he attributed the subsequent pain in the chest wall, shoulders, and neck to this accident. Rest and local treatment did not relieve his symptoms. He was *x*-rayed, and was found to have a destructive lesion in the cervical vertebrae. He was diagnosed as a case of tuberculosis of the spine, and was accordingly admitted to this sanatorium. On admission (December, 1927), temperature and pulse were normal. The patient complained of pains in the neck and shoulders. For the previous three or four days he had had difficulty in swallowing. He also showed a slight degree of dyspnoea. These symptoms could be accounted for by a bulging of the pharyngeal wall, which did not feel like an abscess. The subsequent *x*-ray picture proved that the atlas was dislocated forward on the axis and that the first three cervical vertebrae were carious.

Fixation on a double abduction frame with head extension gave only temporary relief. Pain became localized in the right arm. Two months after admission, a bony swelling appeared in the lower third of the humerus, which the radiologist diagnosed as a non-tuberculous lesion and most suggestive of a syphilitic infection. This diagnosis was confirmed by a positive Wassermann reaction. Administration of neokharsivan brought about an uninterrupted recovery in the spinal condition, which proved to be soundly healed twelve months after admission. In spite of treatment, however, a pathological fracture occurred through the gumma in the humerus four months after the onset of symptoms, and this failed to unite.

The patient was sufficiently well to be discharged in February, 1929 (fourteen months after admission), and to continue treatment outside.

CASE II

Male, aged 41, also gave a history of rheumatism over a period of at least ten years. For eighteen months before admission, abscesses had appeared over the sternum and in the region of the parietal bones. These had broken down, but scars proved that some of the lesions had healed spontaneously. On admission (February, 1928), there were several discharging sinuses over the sternum and the skull. Temperature was 100° to 97°, pulse rate 96 to 76. The multiple character of his lesions and the history suggested examination of the blood, which gave a positive Wassermann reaction.

About three weeks after admission, the patient complained of pain and stiffness in the neck. As this did not yield to ordinary treatment he was *x*-rayed. This time it was found that the body of the third cervical vertebra showed early destruction.

The patient rapidly improved under administration of neokharsivan, in addition to the application of a surgical support. Radiologically, the lesion was soundly healed at the end of nine months, and in September, 1928, he was discharged to attend hospital as an out-patient.

Interesting points are as follows:

1. The diagnosis in the first case was dependent on the *x*-ray findings.

2. The situation of the lesion in both cases was in the cervical spine.

3. Abscess formation frequently accompanies a tuberculous lesion, but is not typical of syphilitic caries. In this first case the suggestive retropharyngeal swelling was due to dislocation.

4. In both cases the Wassermann reaction was strongly positive, and was still positive, despite treatment, when the patients were discharged.

Of the few cases reported in this country, the earliest was a case of exfoliation of the atlas, described by Keate in 1835. Wade,[1] in 1849, recorded another case of cervical caries. Evans and Marshall[2] published a case in 1920. From the literature, Ziesche[3] collected eighty-eight cases, and found that in 75 per cent. of these the lesion was situated in the cervical spine.

I am indebted to Dr. C. Rundle, medical superintendent of Fazakerley Sanatorium, for his kindness in permitting me to publish these cases, and also to Mr. J. T. Morrison, visiting surgeon to the sanatorium.

A CASE OF PULMONARY ASBESTOSIS

BY

H. E. SEILER, M.D., D.P.H.

DIVISIONAL MEDICAL OFFICER OF HEALTH, PUBLIC HEALTH DEPARTMENT, GLASGOW

AND

MARY D. GILMOUR, M.A., M.B., CH.B.

ASSISTANT PATHOLOGIST, PUBLIC HEALTH DEPARTMENT, GLASGOW

(With Special Plate)

The problem of the production of industrial fibrosis of the lungs by the silicate dusts, and notably asbestos, has, because of its evident importance, received increasing attention during the past few years. It is felt, therefore, that some further notes on the after-history of one of the earliest reported cases of pulmonary asbestosis may be of interest. This case, reported by one of us in the *British Medical Journal*,[1] was the first in which the relationship between the inhalation of asbestos dust and fibrosis of the lung could be satisfactorily established: the essential factors being—exposure to asbestos

dust, the presence of a definite pulmonary fibrosis demonstrated clinically and radiologically, and the absence of a history of previous infection, or of exposure to other dusts known to cause pulmonary fibrosis. Two other cases, the "Montague Murray" case[2] in 1906 and "Cooke's" case[3] in 1924, had been previously described; and, in addition, Simson[4] had reported fibrosis in workers employed in crushing asbestos rock as apart from those employed in the manufacturing processes. In most of these cases, however, the fibrosis had been associated with either a pulmonary tuberculosis or an unresolved pneumonia, and it was doubtful whether asbestos dust could of itself produce a disabling fibrosis. Since the publication of these cases, the recent extensive and exhaustive researches on this subject by Dr. E. R. A. Merewether[5] have definitely established the existence of pulmonary asbestosis as a clinical entity, and have amplified our knowledge of the clinical characteristics of the disease and its distinction from silicosis. So far, however, little information about the pathological findings in cases uncomplicated by pulmonary tuberculosis or other gross changes has been obtained. Wood and Page[6] have published the details of one such case, and two others are quoted by Merewether, together with the detailed examination of a few cases by M. J. Stewart.

The patient who is the subject of these notes has died, and the fact that pathological examination showed that death was due solely to cardiac failure secondary to back pressure resulting from the massive generalized fibrosis and irrespective of any added infection is an additional point of interest in his case.

CLINICAL NOTES

The patient, a man aged 42, had been associated with the asbestos industry since boyhood. The total period of employment in the asbestos industry was 24½ years, for 23¼ years of which he was definitely exposed to the inhalation of asbestos dust. He had worked four and a half years in the cardroom, seven and a half years as a dry cloth weaver, and for the remainder of the time in the manufacture of millboard. The last-named is not in itself a dusty process, but exposure to dust from other processes was experienced for most of the time. It is probable that the foundations of his fibrosis were laid in the course of his work in the former two processes, which were definitely dusty, and that work in the millboard section had little effect.

As previously reported, he came under observation for the first time in February, 1928, as a suspected case of pulmonary tuberculosis. He complained of cough, breathlessness, loss of weight, and lassitude extending over a period of several months. Clinical examination at that time, however, did not suggest a diagnosis of pulmonary tuberculosis, and the association of the illness with his occupation was strongly suspected. The physical signs in the chest were those of a widespread fibrosis of both lungs and bronchitis; radiographic examination revealed a diffuse fine mottling of a silicotic nature spread throughout both lungs. The results of these examinations, together with the absence of a history of previous illness likely to produce a pulmonary fibrosis in a man who had not been exposed to other dusts, pointed definitely to a pulmonary fibrosis resulting from the inhalation of asbestos dust.

The patient was admitted for institutional treatment on March 27th, 1928, and he improved to such a degree that five months later it was possible to discharge him. He had gained weight, only a slight degree of cyanosis was present, and dyspnoea and cough were much less marked. Following his discharge from hospital, he was absent from work for a further period of nine months. However, he remained well, and was able to return to the asbestos factory and work as a supervisor of a practically non-dusty process. He continued at this work for twenty months, until December 3rd, 1930. For a few months before this date his general condition had again deteriorated, and he complained of increasing breathlessness and an exhausting cough. At the beginning of December, 1930, he noticed swelling of the ankles, and a week later his condition became so serious that he was removed to hospital.

His condition was now much worse; he was thin, with an anxious appearance, extremely cyanotic, and his breathing was very distressed. There was marked clubbing of fingers, and oedema of the lower limbs extending up to the thigh. The pulse was regular, rapid, and of low tension. The temperature was subnormal, and remained so during the illness. The cardiac dullness was definitely increased, and the heart sounds muffled with a soft systolic murmur at the apex. The percussion note was impaired over the whole of both lungs, varying in intensity, complete dullness being noted at the left base. On auscultation, moist rales and crepitations obscured any finer changes in the respiratory murmur. In spite of treatment, no improvement occurred on this occasion, and he died on December 30th, fourteen days after admission.

PATHOLOGICAL FINDINGS

At necropsy generalized anasarca was present. Face, neck, and shoulders were deeply cyanosed, and the conjunctivae were injected.

The right pleural cavity was obliterated by extremely dense fibrous adhesions, the whole of the right lung being invested with a greatly thickened membrane. The left pleural cavity contained a massive serous effusion. No adhesions were present on this side, but the visceral pleura showed irregular patchy fibrosis. Both lungs were very firm on palpation, and on section the lung tissue was remarkably tough and airless. All lobes were affected, so that there appeared to be no spongy lung substance left. The cut surfaces presented a curiously uniform, dense, fibrous appearance, dark grey with deep red mottling—the latter colour due to chronic venous congestion. A great increase in the connective tissue of the interlobar septa and deep layers of pleurae was present. The right lung, which was bulkier and tougher than the left, was obviously in a more advanced stage of the disease. Some large emphysematous bullae were present along the anterior border of the left lung. There was no evidence of any tuberculous process. The bronchi were not notably dilated; large glands, deep black in colour, were present at the roots. The heart and other organs showed all the signs of advanced cardiac failure. Hydropericardium was present. There was marked hypertrophy and dilatation of the right ventricle, with engorgement of the venous circulation, as evidenced by the condition of the viscera. The liver showed the typical nutmeg appearance of chronic venous congestion. Ascites was present. The spleen and kidneys had the hard consistence and purple colour of cyanotic induration.

Histological Examination

Sections from all lobes of both lungs were examined; and two outstanding changes were noted: first, a diffuse fibrosis; secondly, the presence of golden-yellow bodies.

Every structure in the lung was affected by the fibrosis. The alveolar epithelium showed reversion to the cubical embryonic type, and in parts was replaced by adult fibrous tissue. There was fibrosis of the walls of bronchi and vessels, many of the latter being the seat of thrombosis and endarteritis obliterans. In situations where fibrous tissue is naturally abundant, as in the septa and the deeper layers of the pleurae, the fibrosis was extreme, and consisted of very dense collagenous bundles, in some of which there was a deposit of lime salts. Collections of lymphocytic cells were scattered irregularly throughout, often in relation to new blood vessels in the fibrous tissue. Unlike the distribution of the fibrosis in silicosis, there were no fibrous nodules or whorls. Side by side with the fibrosis, emphysematous areas were occasionally seen with accompanying chronic venous congestive changes. A desquamative condition of the lining of the bronchi and bronchioles accompanied the fibrosis in their

walls, filling the lumina with epithelial and round connective-tissue cells. The absence of polymorphonuclear cells in bronchi or elsewhere was a conspicuous feature. No evidence whatever of a tuberculous lesion was found, or of acute pneumonic consolidation.

Asbestosis Bodies

The curious asbestosis bodies, so prominent a feature in cases already described by Cooke,[7] Simson,[4] Stewart,[8] and Lynch and Smith,[9] were abundantly present in all areas of both lungs. The bodies were generally golden-yellow in colour, and of great variety of shape and size. Many showed core, thought to be asbestos fibre, running down the centre of the body (Fig. 1); and in a few places the bare, translucent fibre itself was seen, with yellow deposit confined to the ends. Usually, however, the fibre was uniformly coated or encrusted with the yellow deposit (Fig. 2). The deposit gave the prussian-blue reaction for iron. The probable mode of formation of these bodies has been described in detail by McDonald.[7] In addition to the bodies, much yellow pigment in the form of granules and globular masses was seen (Fig. 2). All were to be found lying free or phagocytosed inside air vesicles and bronchioles, and embedded in the alveolar walls, or in the interstitial connective tissues (Fig. 1). Much of the finer dust was found within the endothelial cells of blood vessels, and in the peribronchial lymphatic glands. A few of the smaller bodies were also seen inside the lymphatic glands. A large amount of black carbon pigment was present throughout the tissues. Frequently both yellow and black pigments were phagocytosed within the same cell.

The photomicrographs are by Mr. Boot, Public Health Department, Glasgow.

ROUTINE RADIOGRAMS FOR INVESTIGATION OF INTESTINAL OBSTRUCTION

BY

E. T. C. MILLIGAN, M.D., F.R.C.S.

AND

GEORGE SIMON, M.B., D.M.R.E.

CHIEF ASSISTANT, X-RAY DEPARTMENT, ST. BARTHOLOMEW'S HOSPITAL

(With Special Plate)

Localization of the site of intestinal obstruction before operation for its relief facilitates the surgeon's task, and so is of incalculable advantage to the patient.

Opaque meal and enema given for *x*-ray investigations in these cases are not infrequently a source of peril, precipitating complete obstruction where partial obstruction already exists, and, apparently, subjecting all cases of abdominal section to the risks of post-operative paralytic ileus if time, which can often be ill spared, is not taken to clear the alimentary tract of residual barium. Furthermore, delay in operative treatment for the necessary *x*-ray examination and emptying of the bowel is frequently detrimental to the patient's interest; indeed, in some cases where urgent symptoms are present, evacuating methods must be abandoned, although harmful barium still lies in the bowel.

Discussions and writings on such topics as blind caecostomy and methods of search for the site of obstruction at operation are tacit admissions of inability, in many cases, to localize the site of obstruction by clinical methods until surgical exploration is performed. Enlightenment in this difficult matter of localization would therefore be acceptable, since a feeling of assurance would be inspired and a convenient abdominal wound might be substituted for an unsatisfactory exploratory incision. Instances are not wanting where, after a difficult, dangerous, and fruitless search (through an ill-planned incision) among greatly distended intestines, a colostomy or caecostomy has been performed, and the site of obstruction revealed only by subsequent *x*-ray investigation with opaque materials, or by further operation of an exploratory nature.

Invaluable information in cases of intestinal obstruction, paralytic and organic, in the small or large gut, is obtained by a routine simple radiogram of the distended abdomen before operation, without the aid of opaque substances (barium enema or meal), and without preparation of any kind. Imprisoned gases outline with striking definition the position, size, and extent of the distended bowel on an *x*-ray film, the distended large gut being readily distinguished from the small intestine. The gas-filled caecum stands out prominently and characteristically. The site of obstruction in large bowel is marked by an abrupt ending of the gas-distended bowel. The contracted bowel, empty of gas, below the obstruction is not apparent on the film, thus lending striking definition to the place of obstruction.

The limitations and applications of this somewhat neglected and unfamiliar method will soon be learned by the surgeon who checks and confirms the *x*-ray interpretations by his operative findings. We have found that routine pre-operative *x*-ray investigation has given invaluable diagnostic aid in cases of small intestine obstruction, paralytic ileus, and large intestine obstruction; and often reveals, what is so important to the surgeon, the site of obstruction.

X-RAY TECHNIQUE

The examination should be carried out as soon as the patient reaches the department, and must be conducted rapidly, with as little disturbance as possible. A single posterior view of the abdomen is usually sufficient. Owing to the gaseous distension large films (17 by 14 inches) should be used if available, or important distended coils may be missed. Alternatively, two exposures at different levels on smaller films (15 by 12 inches), placed horizontally, may be employed. The Potter-Bucky diaphragm is essential, and very gentle compression helps to steady the parts. A soft ray, produced by not more than 75 K.V.P., will bring out the translucent gas areas to the best advantage, while a sufficient milliamperage should be used to enable the exposure to be made in less than four seconds, as the patient is usually too ill to hold the breath longer.

Six illustrative radiograms with explanatory notes are reproduced on the Special Plate. It should be noted that Fig. 3 has been turned through a right angle.

We acknowledge our great indebtedness to the radiological departments of the Croydon General Hospital, St. Mark's Hospital, the Weir Hospital, and the Woolwich War Memorial Hospital for their ready co-operation in the immediate radiographic investigation, often at inconvenient hours, of cases of intestinal obstruction on which this article is based.

A CASE OF ACUTE BRONCHIOLECTASIS

BY

H. HILTON STEWART, M.D., M.R.C.P.
ASSISTANT PHYSICIAN, ULSTER HOSPITAL FOR CHILDREN

AND

J. H. BIGGART, M.B., B.CH.
BELFAST

(With Special Plate)

In view of the rarity of this condition the following case seemed worthy of report.

CLINICAL HISTORY

A female child, aged 3 months, was admitted to the Ulster Hospital for Children, Belfast, with a history of cough for a few days, associated with great difficulty in breathing. On examination the child was pale, the alae nasi were working, and a hard cough was frequent. The temperature was 99°, pulse rate 160, and respiration rate 60. There was some dullness at the base of the right lung. Bronchial breathing was present over both lungs, and there were numerous scattered rhonchi. A diagnosis of broncho-pneumonia was made, and the subsequent course of the disease seemed to confirm this. The temperature varied from 100° to 101°, pulse rate between 140 and 160, and respiration rate between 40 and 50. At the end of one week the temperature fell to 99°, and pulse and respiration rates fell proportionately. There was some clinical improvement in the child, but she remained very pale, and in a few days began to get worse, with some increase in dullness at the right base. An *x*-ray photograph of the chest was taken. This showed general consolidation of the right lung, and also some consolidation at the left apex. Fourteen days after admission the temperature rose to 103° and pulse rate to 148. On the morning of the sixteenth day the patient died.

POST-MORTEM FINDINGS

Both lungs were swollen and oedematous. At the left apex and along the lower border of the right middle lobe were many small yellowish areas, each about the size of a small pea. On section the left apex was seen to be riddled with cavities and abscesses. The yellowish areas were small abscesses. The remaining lung tissue showed the presence of a broncho-pneumonia. The right lung also showed the presence of abscesses in the middle and lower lobes.

Microscopically an extensive broncho-pneumonia and bronchiolitis were present. The cavities and abscesses were found to be dilated bronchioles. Many of the abscesses were definitely formed by dilatation of a terminal bronchiole and of its infundibulum. The lung tissue surrounding the dilated bronchioles showed inflammatory consolidation and partial collapse. The bronchi were congested. Gram's stain showed the presence of large numbers of staphylococci in the abscess cavities. No other organism was found.

The liver, kidneys, and spleen showed well-marked toxic changes. No sputum was available for a more complete bacteriological investigation.

COMMENTARY

Clinically it would seem impossible to make a differential diagnosis between this condition and broncho-pneumonia. This is also the opinion of Ewart.[1]

The pathogenesis of the disease is difficult to elucidate. The comparative rarity of bronchiolectasis makes it impossible to believe that it is compensatory in origin. Furthermore, dilatation of the bronchi and bronchioles is more apt to occur in a pneumonic lung while resolution is taking place rather than while the consolidated lung affords support to their walls. In this case, however, it is worthy of note that a certain amount of collapse accompanied the consolidation. It may then be possible to find an explanation for the bronchiolectasis in (1) an inflammatory softening of the wall; (2) an infection by the staphylococcus causing well-marked local destructive changes; (3) the presence of a certain degree of peribronchiolitic collapse. The infection is evidently primarily a bronchiolitis with subsequent broncho-pneumonic changes.

The case is interesting, in so far as it shows the condition to be relatively localized, and not general as in the cases reported by Sharkey.[2]

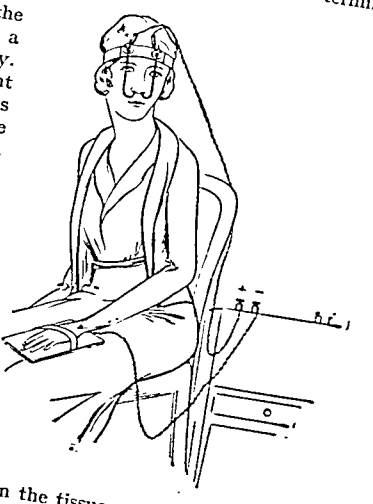
Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

TREATMENT OF HAY FEVER BY INTRANASAL ZINC IONIZATION

The problem of hay fever has been studied from many angles. Of recent years specific and non-specific desensitization has yielded only moderate results. The uniformly successful cures that I have obtained with the method described below encourages me to place on record the technique I have adopted during the last six years.

The treatment consists of intranasal zinc ionization. Cases of hay fever have been successfully treated before and during an attack, as well as those of vasomotor rhinitis—that is, cases showing manifestations of hay fever throughout the year. The majority of cases require two treatments, with an interval of seven days. The number of treatments depends on the success of the intranasal impregnation with zinc. In some cases one treatment has sufficed. The intranasal mucosa is covered with thin layers of cotton-wool soaked in a 1 per cent. solution of zinc sulphate in distilled water. Particular care should be taken to cover the middle turbinate and the adjacent septal mucous membrane. A zinc terminal is placed in each nostril and connected with the positive pole of a galvanic battery. The indifferent electrode is applied to the forearm or hand. A current of three to five milliamperes is passed for fifteen to twenty minutes. A simple apparatus for applying the terminals to the nose has been devised by me, as shown in the illustration. Should the treatment be commenced at the outset of an attack when the tissues are swollen and irritable, it is advisable to spray a 4 per cent. solution of cocaine into the nose before applying the wool. Careful application is necessary to avoid any abrasion of the tissues. Undue injury may give rise to epistaxis. A metallic taste and an increased salivation is experienced when the ionizing process begins; a conjunctival hyperaemia, with lacrymations and blushing, is noticed as the treatment continues. On removal of the packing the tissues are contracted, and the turbinal and septal mucosa are covered



with a white coating which persists for several days. The treatment is not followed by any untoward symptom, although attacks of sneezing may occur during the subsequent twenty-four hours. The nasal tissues, however, remain definitely shrunken. The twenty-five patients treated by this method include three with vasomotor rhinitis and twenty-two with seasonal hay fever. All the latter had suffered annual attacks, and between them had tried every known method of treatment. The ages ranged between 19 and 39, excepting two children aged 10 and 14, and one medical man, aged 57. In the latter case a septal deflection had to be corrected to enable the nose to be packed. Three patients treated in 1925, one in 1927, and one in 1929, have been free from attacks and required no further treatment. Unfortunately the result is not always permanent, and although the patient may be free during the subsequent hay fever season, the attack may recur the following year.

Miss M. W., aged 20, had annual attacks for eight years. First treated by ionization in 1929; no further symptoms. In 1930, no treatment; severe hay fever. In 1931, started an attack on May 20th, treated by ionization followed by immediate cessation of the attack, with no recurrence to date.

None of the patients has had attacks during the season following treatment, so that their subsequent course calls for no comment.

The apparatus illustrated was made and supplied by Messrs. Theodore Hamblin, Ltd., 15, Wigmore Street, W.1.

Reports of Societies

RECENT ADVANCES IN CHEMISTRY OF THE VITAMINS

DISCUSSION AT THE ROYAL SOCIETY

The Royal Society took advantage of the presence in London of a number of distinguished investigators in the field of vitamin research to hold a meeting on June 18th for a discussion on recent advances in the chemistry of vitamins.

Sir F. G. HOPKINS, President of the Society, said that in the room in which they were assembled the scientific work of successive generations of investigators had been reviewed for the first time, and of late years discussions had taken place there which had illustrated many new aspects of science; but of the progressive and very important branch in which those gathered on that occasion were specially interested very little had been heard in the Royal Society, and only two or three papers on vitamins had been communicated. It was time, therefore, for a discussion on this subject, and he felt a personal satisfaction that it should take place during the first year of his presidency. It was the chemistry of vitamins, rather than their physiological aspects, which would be reviewed, and since his own contribution to chemistry was negligible he did not propose to open the discussion from the chair, but only to suggest the general lines on which it might take place. It seemed to him that attention might well be given to three vitamins—namely, D, A, and B, and in that order—though with regard to B he felt a certain anxiety as to what the discussion might reveal—whether another B might not join the "hive" at any moment. With regard to vitamin D, recent years had seen an extraordinary convergence of various lines of work in the endeavour to reach a real understanding of the nature of this important agent.

Vitamin D

Professor A. WINDAUS (Göttingen) presented an account of his work on the chemistry of irradiated ergosterol. Since it became known that ergosterol on irradiation with ultra-violet rays was converted into an antirachitic substance of high activity, the study of the most favourable conditions for this photochemical process had continued. Attempts had been made to prepare the substance in a crystalline condition, but so long as success in its purification had not been attained the investigations had to be carried out with the crude irradiation product, the vitamin content of which was unknown. In the process of irradiation no state of equilibrium between ergosterol and its irradiation products was attained. If the irradiation was continued for a sufficiently long time the ergosterol disappeared completely, and there took place a conversion into over-irradiated products, of which two had been obtained in crystalline form. Vitamin D was only an intermediate product of the chemical transformations of ergosterol, and so it was sensitive to irradiation with ultra-violet rays. The two products of over-irradiation just mentioned were end-products of the chemical transformation, and neither could be converted into the other. During the ultra-violet irradiation of ergosterol it appeared possible that several substances were formed simultaneously, but in his view it was not permissible to draw such far-reaching conclusions as some had ventured. It appeared very probable, though on the evidence not absolutely certain, that the vitamin obtained contained three double bonds, as did ergosterol itself. It had been proved that the crude irradiation product lost its antirachitic action when treated with sodium and alcohol. There was no doubt that vitamin D contained a system of conjugate double bonds, and that in this respect it was very similar to ergosterol. On the other hand, the vitamin was much more sensitive to the action of high temperatures. The question whether vitamin D could be preserved unchanged in the absence of air had been discussed, and it had been proved that so far as the crude irradiation products were concerned changes took place in the spectrum and optical rotation with age even when air was carefully excluded, but there was no decrease of physiological activity corresponding to this rapid change; thus it was concluded that the substance which changed with age was not the vitamin. The fact that the antirachitic and toxic actions ran parallel supported the view that both reactions were caused by the same substance. The workers had been spurred on to attempt to obtain the vitamin in its pure crystalline state; such attempts had not seemed completely hopeless, for in vacuum tubes crystals had repeatedly separated. Professor Windaus related the successive attempts in his laboratory to find a reaction which would result in the chemical separation of the crystals. This had at last been achieved, and he showed lantern slides of the crystals and their absorption spectra. The crystals were long, well-formed needles; the spectrum showed a band of main absorption at 265–270 $\mu\mu$, the absorption coefficient being 1.44. The limiting antirachitic dose had been determined to be two and a half times as active as that of the English standard preparation.

Dr. R. B. BOURDILLON (National Institute of Medical Research) said that crystalline products of high antirachitic activity had now been obtained in three laboratories—in Germany, Holland, and England. He spoke as a representative of eight workers at the Institute of Medical Research who had obtained in some quantity a crystal product which appeared to be very similar to that shown by Professor Windaus. The crystals had been obtained by a distillation process in quantities of two or three grams on a number of occasions, and a comparative study of their properties had been made. The antirachitic activity, expressed in Medical Research Council units, was between 18,000 and 20,000 units per milligram. The workers had ventured to give to this product the name of calciferol. The product had the same composition as

ergosterol, and its molecular weight was the same. Three different workers had now obtained the crystalline product. It was impossible to say whether the products were exactly identical. The antirachitic activity was similar, and possibly the optical rotations were approximately the same, though this could not be said with certainty. He thought it safe to say that all these products contained at least one substance which was essentially vitamin D, or a vitamin D, and that they were not negative products contaminated by traces of a mysterious and hitherto unknown vitamin.

Dr. OTTO ROSENHEIM (London) thought that the substance described by Professor Windaus as prepared by a chemical method and that by Professor Bourdillon and his co-workers were identical, though there might remain in both a certain amount of impurity. It was fitting that the isolation of the crystalline substance should have been worked out in two laboratories in which the announcement of the transformation of ergosterol into vitamin D was first made. He could not help expressing some disappointment that the hopes which had been raised that photochemistry and spectroscopic examination would help rapidly to a solution of the problem had not been fulfilled. Four years ago it looked as if this would come about, but now, in spite of the most laborious study, it could not be maintained that the observation of the spectroscopic behaviour of the ergosterol derivatives had contributed to any extent to the isolation of these crystals. It was a satisfaction to him as a biochemist that the success should have been due to biological and organic chemical research, although it was true that distillation was a physical process.

Vitamin A

Professor H. VON EULER (Stockholm) introduced the subject of vitamin A. He said that at the beginning of the study of vitamin A it was soon observed that carotene must be the substance which had growth-promoting activity. New experiments showed that there were two carotene substances with different melting-points, one optically active and the other not. This problem of carotene had been worked upon at Stockholm for more than a year. It was found that the absorption spectrum of one of the artificial derivatives of carotene was very similar to the spectrum believed to be characteristic of vitamin A in cod-liver oil. According to the interesting work of Moore of Cambridge, carotene when administered to rats per os was converted into a very active substance, *a*-carotene. It was now an interesting question whether carotene was transmuted in the organism into vitamin A, or whether carotene and vitamin A were different substances having distinct activities. In his own laboratory the attempt had been made to obtain conversion *in vitro*, and after various unsuccessful attempts to bring about this transformation in macerated livers of different animals they had at last achieved the conversion in the serum of hens to which carotene had been added. The concentration of carotene given in this way was in a short time diminished, and a new substance was formed, spectroscopically almost identical with vitamin A. In connexion with this transmutation of carotene into vitamin A, the question arose as to where it took place, whether in the liver or in another organ. Experiments showed that the first decrease of carotene occurred in the serum, and it seemed probable that the transmutation was effected in the blood.

Vitamin B

Professor B. C. P. JANSEN (Amsterdam) spoke briefly on the vitamin B complex. Using a suggestion made by Seidel, he had employed the classical precipitating agents and had succeeded in obtaining crystals, though in very small quantities (of the order of 30 milligrams). Dr. SEIDEL (Tübingen) said that he was pleased that Dr. Jensen, using a very slight suggestion that he himself had made, had achieved success. He himself, being something of an iconoclast and disinclined to follow the lead of others, had never used precipitating agents if he could avoid them; he had used instead the benzol reaction which had been a useful procedure in his hands for reducing impurities. Without applying precipitating agents he had succeeded in obtaining much larger quantities of material than Dr. Jansen had obtained, but it would not crystallize. Tested on rats, however, it proved to have an activity in the neighbourhood of that of the crystals. He hoped that work in both these directions for obtaining the active product might prove successful—the one which took advantage of precipitation methods, and the other which avoided them—and if they both led to products which were of the same type physiologically it would afford a still better confirmation of the unity of vitamin B. Dr. R. A. PETERS (Oxford) put forward the view that the ultimate solution of the problems in connexion with vitamin B complex would not be reached except by taking into account the physiological side as well. With regard to Dr. Jansen's crystals, these had been found to be very marked in B_4 activity. By fractional distillation with charcoal, B_1 could be separated almost completely from $B_{4'}$ but it was not possible quite so certainly to make B_4 completely free from B_1. B_1 and B_4 activities were present in different proportions, so that there was an inclination to think that they did represent two quite different activities.

Dr. H. STEENBOCK (Wisconsin) said how much he had been interested in the physiological problems connected with vitamin D, and especially with its possible relations with the endocrines, but owing to some inadequacy of technique the solution had so far eluded him. Professor E. V. MCCOLLUM (Johns Hopkins University), who was also invited to speak, said that his own contributions to researches in nutrition had been along lines other than those which formed the subject of the present discussion. He remarked that the reading of a paper twenty-three years ago by Professor Hopkins had furnished the stimulus which had kept him active in nutritional observations down to the present day.

The PRESIDENT said that the discussion might well end on an optimistic note. The progress of the last few years most decidedly made for optimism. It was a remarkable thing that the discovery of vitamin D crystals should have come from three centres almost simultaneously. He felt that the knowledge of the actual constitution of vitamin D was within measurable distance. For all vitamin research the future was bright.

TREATMENT OF IMPOTENCE

At the meeting of the Medical Society of Individual Psychology on June 11th, with the president, Dr. O. H. WOODCOCK, in the chair, a discussion was held on the treatment of sexual impotence by the methods of individual psychology.

Dr. J. YOUNG defined sexual impotence, for the purpose of his remarks and in conformity with the spirit of Adler's teaching, as "incapacity to perform the normal act of generation to mutual content with a person of the opposite sex." He thus included under this heading all forms of sexual incapacity, whether of the male or of the female, together with homosexuality and the perversions. He held that, in the absence of any gross structural defect, sexual disability was ultimately psychologically determined. He agreed with Adler that the sexual urge was moulded by the subject's "style of life." From this it followed that only in connexion with the personality

as a whole could abnormal modes of sexual behaviour be rightly understood. Frigidity and vaginismus were forms of resistance to the attainment of full maturity. The unhappy results which sometimes occurred when a frigid woman became a mother, he attributed to that general immaturity of which her frigidity was one symptom. Psychic impotence in men illustrated the justice of Adler's insistence upon the necessity for love in marriage. The same attitude held good for other travesties of sexual function, which, as he showed by reference to ejaculatio praecox, might be almost as distressing as complete impotence. He attributed the prevalence of sexual impotence to the unfortunate influence exerted by society upon the life-style of its members. This fact did not, however, exonerate individuals from responsibility. It was only by the efforts of individuals that society could be changed, and perhaps nowhere more signally than in the matter of impotence.

Dr. F. G. CROOKSHANK agreed with Dr. Young's definition of sexual impotence, implying as it did that sexual incompetence was a special manifestation of incomplete social adaptation. He said that the theory of individual psychology was closely interwoven with successful treatment, since both alike involved complete understanding. Absolute comprehension meant absolute power. He touched upon the methods of individual psychology, and upon the necessity for a complete examination of the patient, physical as well as mental. The various forms of sexual incompetence reflected the whole life study of the individual concerned. Thus masturbation was the behaviour adopted by the timid, immature individual in place of courageous, forward adjustment. The same applied to some extent to homosexuality. His opinion that this condition was acquired, not innate, and therefore amenable to encouragement and re-education, was justified by the good results of treatment by the methods of individual psychology. Other forms of sexual incompetence illustrated the same points. He referred to the weak egoism of the subject of ejaculatio praecox, and the self-satisfied desire for domination of the really frigid woman. Dr. Crookshank said, in conclusion, that treatment in all cases involved the general adjustment of the individual to the whole of his life needs. In marriage, which was essentially a constructive task for two persons, love played a fundamental part. It formed the basis upon which successful and truly happy marital relations were surely established.

Dr. NORMAN HAIRE, while fully recognizing the psychological element in many cases, insisted that attention must be paid to local organ-inferiorities; he supported Dr. Young's view of the social aspect of sexual incompetence. Dr. LEAHY gave an account of his personal methods. He stressed the elements of fear and discouragement so generally present in the patient, and the necessity for the restoration of self-confidence.

Mr. KENNETH WALKER said that he, as a surgeon, had come to feel more and more strongly that, however important the local organic changes and conditions, yet they often stood in the same relation to a general state of anxiety and neurosis as did the tache cérébrale to meningitis. He felt that, when he had done his best, or his all, there still remained much for the psychologist to grapple with. He was glad to have heard that evening of the work and methods of the school of Adler, with which he had hitherto been little acquainted. Mr. RALPH THOMPSON narrated several cases in which sexual potency existed in spite of apparently gross physical disability. Like other speakers, he appreciated the responsibility of social conditions and the scope for psychotherapy. Dr. G. GORDON mentioned the factor of psychical incompatibility as operative detrimentally in the consummation of marital relations.

Reviews

PSYCHOPATHOLOGY

Dr. ERNEST NICOLE has written a volume entitled *Psychopathology: A Survey of Modern Approaches*,[1] in which his aim is to epitomize the concepts of the different schools of to-day, emphasizing theoretical backgrounds rather than practical applications. In successive chapters the author outlines Freud's psycho-analysis; Adler's individual psychology; Jung's analytical psychology; Rivers's theories; Watson's behaviourism; Kempf's psychopathology; Berman's endocrinal attack; various biochemical and physiological contributions; Kretschmer's constitutional approach; and, finally, the teaching of the "combined" schools. An attempt is made by Dr. Nicole to show some of the points at which different lines of approach meet or at least approximate to one another. In spite of this effort at co-ordination the reader may find it somewhat difficult to digest this heavy meal of theories. No doubt in course of time it will be possible to give a more compact and uniform account of psychopathological teaching than can now be attempted. The complexity of his subject-matter is not, however, the fault of the author, and this book should be helpful to those who wish to gain in a condensed form some understanding of the various theories with which it deals. The book includes three appendices, consisting of papers previously published in the *Journal of Mental Science*.

In *The Unknown Self*,[2] by Dr. GEORG GRODDECK, we have presented, as the subtitle of this book indicates, "A New Psychological Approach to the Problems of Life, with Special Reference to Disease." The author is a physician with original and independent views, an artist rather than a scientist, and evidently has "personality." If it is desired to label Dr. Groddeck, the term "vitalist" would be applicable, for he assumes the existence of purposive entity—the It—which controls both the ego and all organic processes. Thus for motives only known to itself the It determines the sex, "decides" whether the stature should be tall or short, controls the physiological activities, and cures the individual of diseases on the one hand, or "makes up its mind" to make him ill, on the other. The book, which ends up with a Christmas story, is interesting and entertaining. It gives the impression that the writer is a very enthusiastic physician, who no doubt does his patients a great deal of good; that is to say, we anticipate he will often succeed in persuading their Its to view favourably the notion of recovery. If this book is to be enjoyed and appreciated the conception of the It should not be taken quite seriously, but rather as a poetic symbol expressing somewhat the same idea as the old aphorism—"The doctor binds the wound, God heals it."

VENEREAL DISEASES

The fact that a new edition of Dr. DAVID LEES'S *Practical Methods in the Diagnosis and Treatment of Venereal Diseases*[3] has appeared is a sign that it has established itself as a textbook for medical practitioners and students. Although much new matter has been included in the new

[3] *Practical Methods in the Diagnosis and Treatment of Venereal Diseases.* By David Lees, D.S.O., M.B., D.P.H., F.R.C.S., M.R.C.P.Ed. With introduction by William Robertson, M.D., F.R.C.P., D.P.H. Second edition. Edinburgh: E. and S. Livingstone. 1931. (Pp. xx + 634; 87 figures, 8 plates. 15s. net.)

volume the author has wisely avoided the temptation of adding materially to its length. Moreover, he has maintained the general character of the previous edition.

This is essentially a practical work. Although it contains references to literature one feels on reading the book that it is from his immense stock of material at the Edinburgh Royal Infirmary rather than from literature that the author has derived his facts. Practically all the methods of treatment that he advocates have been tested by experience, and his opinions of their value are based on first-hand knowledge. The most important additions are the chapters on cardio-vascular syphilis and the expansion of the sections dealing with neurosyphilis. Recent work has tended to emphasize still more strongly the fact that syphilis is primarily a disease of the arteries. Indeed, it has been shown that very seldom if ever do the arteries escape, however early and however complete may be the treatment given. Hence syphilitic aortitis is at least as frequent and as serious a sequel of infection with the *Spirochaeta pallidum* as are tabes and general paralysis. For this reason the author's precise instructions for the treatment of aortic disease in a middle-aged man will be of great value to all who are called upon to treat, not only the early, but the late stages of syphilis. In speaking of malarial therapy in tabes he is of the opinion that the effect of this treatment is greater in advanced than in early cases. Of all the arsenobenzol preparations on the market he finds that tryparsamide has the greatest effect in neurosyphilis, but it must be given over long periods if any improvement is to be obtained. However, if conscientious treatment with this drug is carried out not only may an amelioration of the clinical symptoms be expected, but also an improvement in the condition of the cerebro-spinal fluid. In Dr. David Lees's opinion the introduction of tryparsamide by Pearce and Browne has completely altered the prognosis and outlook for many cases of neurosyphilis.

The new edition has been enriched by the addition of eight coloured plates. We have no hesitation in saying that *Diagnosis and Treatment of Venereal Diseases* is the best work on the subject that has appeared in this country. In the reviewer's opinion it is even the best manual in the English language, for although more imposing works may have been published during the last ten years none of them have the same value for the practitioner or student who requires a textbook full of reliable and essentially practical information.

HEREDITARY OPTIC ATROPHY

A very valuable series of memoirs is at present being issued from the Galton Laboratory of Eugenics by Professor KARL PEARSON, under the general title of *The Treasury of Human Inheritance*.[4] A large number of hereditary conditions have already been dealt with, and are comprised in volume i of the *Treasury*. The second volume is to be devoted to *Anomalies and Diseases of the Eye*, and the fourth memoir of this volume, on "Hereditary Optic Atrophy (Leber's Disease)," from the pen of JULIA BELL, has recently been issued. The chief obstacle to the study of the laws of human inheritance is the difficulty encountered in obtaining satisfactory pedigrees, and one of the main objects of the memoirs is to collect together all the available pedigree material at present distributed through the literature. Leber's disease is interesting in this particular as providing a larger number of fully worked out pedigrees than any other condition; the author's plates include no fewer than 238, many of which are very full.

The disease has been known for a hundred years or more, but it was not until 1871 that its clinical features and hereditary etiology were fully worked out by Leber, a fine portrait of whom forms the frontispiece to the memoir. With regard to its transmission, Leber's disease is generally regarded as sex-limited, but the author is inclined to doubt the accuracy of this view, and in a discussion on sex limitation generally she expresses the opinion that probably haemophilia is the only disease that can be considered as truly sex-limited. On the other hand, a marked responsibility of females is noted with regard to the transmission of the disease, and the author ventures the suggestion that if the sisters of affected males were to abstain from parentage the disease would be almost exterminated. The curves relating to the age of onset show a maximum in males between the ages of 20 and 23, the curve falling rapidly above and below that period. In females two maximum points are observed—between 12 and 15 and 24 and 27, with a minor rise between 40 and 43. A curious difference is noted in the Japanese figures, the maximum in these being between 12 and 23 for both sexes. With regard to symptoms, the sole complaint of those suffering from the disease is diminution of vision, and, in rare cases, blindness; there is a central scotoma, interfering with direct vision and disabling from fine work, but leaving the patient with a measure of independence as regards mobility. The prognosis is generally considered unfavourable; complete recovery is infrequent, but improvement is estimated to occur in from 10 to 29 per cent. of the cases.

The first and only anatomical examination of a case of Leber's disease was made last year by Rehsteiner; a full account of the case is to be published in von Graefe's *Archiv*. Rehsteiner found marked atrophy of the ganglion cells and nerve fibres of the retina at the fixation point and in a large part of the immediately surrounding retina, including the papillo-macular bundle, together with a less uniform atrophy of the fibres of the optic nerve. No evidences pointing to an inflammatory origin of the condition were present, but the disease was of seven years' standing, and therefore in a late stage.

THE SMETHURST CASE

Of the fifty-three volumes of the Notable British Trials as yet published, the vast majority are of medical interest, and a certain number of them deal with the crimes of members of our profession, but not one of them exceeds in technical interest the *Trial of Dr. Smethurst*,[5] which has been edited by Dr. LEONARD A. PARRY and recently published. Not only was the accused a doctor, but throughout the trial and the subsequent proceedings medical men and medical matters were of the first importance. The accused was a medical man; the doctor whom he called in to attend the deceased was the first to give information to the police before her death; the astonishing spectacle was presented to a scandalized profession of the leading toxicologist of the day revoking in the box, at the Old Bailey, the damning evidence which he had given before the magistrates; the conflicting evidence of distinguished medical experts in the witness-box and the storm of protest which the verdict and sentence aroused in the medical press; and finally, to crown all, the surprising appeal of the Home Secretary to a distinguished surgeon, to whom he transferred the responsibility of deciding whether the clemency of the Crown should be exercised or not—all this combined to

[5] *Trial of Dr. Smethurst*. By Leonard A. Parry, M.D., B.S., F.R.C.S. With a foreword by John Flowers, K.C. Notable British Trials. Edinburgh and London: W. Hodge and Co., Ltd. 1931. (Pp. xiii + 259; 4 plates. 10s. 6d. net.)

produce a situation unprecedented in our medico-legal annals.

Thomas Smethurst was a retired medical practitioner who, at the age of 54, left his much older wife and contracted a bigamous marriage with a Miss Bankes, a lady of 42 years and some independent means, with whom he went to live at Richmond. The lady soon afterwards was taken ill, the chief symptoms being persistent diarrhoea and vomiting. Dr. Smethurst called in Dr. Julius, one of the best-known practitioners in Richmond, but neither his nor his partner's remedies, nor those prescribed by the celebrated Dr. Todd (who was called in consultation at the prisoner's request) availed to save her, and she died, apparently of exhaustion, but not before she had made a will, by Smethurst's advice, in his favour. Dr. Julius suspected criminal poisoning, and had a stool examined, which was pronounced to contain arsenic. Thereupon he gave information to the police, and Smethurst was arrested, but released on his own recognizances. Miss Bankes died the next day. A number of bottles of medicine and drugs were seized by the police, before Smethurst had any opportunity to tamper with them. He was again arrested, and charged with murder, and answered to the charge in a plea of "Not guilty" in July, 1859. Owing, however, to the illness of a juryman the trial was postponed to the session in August before another jury. Before the trial began the accused objected to being tried by Lord Chief Baron Pollock, on the remarkable ground that the judge was a personal friend of Dr. Alfred Swaine Taylor, an important witness for the prosecution. The objection (after consultation with Mr. Justice Wightman) was overruled.

In the trial which followed, evidence was given to the effect that deceased was from five to seven weeks pregnant. The large intestine was very extensively ulcerated, the small intestine slightly inflamed. Dr. Taylor announced that his evidence of the presence of arsenic in an evacuation which he gave before the magistrates was based on a mistake, for he had since found that the arsenic in question came from his own copper gauze which he used in Reinsch's test. Notwithstanding the strong points in the prisoner's favour of lack of motive and the facts that no irritant poison was traced to his possession nor any found in the body enough to cause death, and that the post-mortem appearances were not those of chronic irritant poisoning, the judge summed up strongly against the accused, and the jury found him, without much hesitation, guilty, and he was sentenced to death.

Thereupon a storm of protest arose in the medical and lay press. The *Times* had two leaders on the subject, and printed twenty-five letters, most of them from medical men, protesting against the execution of the sentence on the ground that there was not sufficient evidence to support the verdict. A very forcible leading article appeared in our columns in which, while stigmatizing Smethurst as a liar, a cheat, and a scoundrel of the blackest dye, it was yet contended that the verdict was against the weight of evidence, and that death was probably due to a natural cause—for example, hyperemesis gravidarum. Dr. Tyler Smith, in his evidence and subsequent letters, strongly supported this theory of the cause of death. Dr. Swaine Taylor was very severely taken to task by the medical press, and the scandalous personal antagonisms of the most distinguished toxicologists were condemned in no uncertain terms in a second article in the *British Medical Journal*. By all this storm of protest and criticism the Home Secretary, Sir George Cornewall Lewis, seems to have been quite bewildered, and he took the unusual course of submitting the papers to Sir Benjamin Brodie, the first president of the General Medical Council and consulting surgeon to St. George's Hospital. Brodie, in his letter of reply, went into many issues entirely unconnected with medicine, pathology, or surgery, and discussed them under fourteen heads, but ended with the following: "Taking into consideration all that I have now stated, I own that the impression in my own mind is that there is not absolute and complete evidence of Smethurst's guilt." Notwithstanding Lord Chief Baron Pollock's severe criticism of Brodie's letter in a personal communication to Sir George, which is included by Dr. Parry in an appendix, the Home Secretary advised the Crown to grant a free pardon. Smethurst was almost immediately tried for bigamy, and sentenced to one year's imprisonment, after which (in 1862) he had the assurance to bring an action in the Probate Court propounding the will of Miss Bankes. The jury decided in favour of the will, and probate was ordered to be granted to the plaintiff. Apparently encouraged by this success, Smethurst presented a petition for compensation to the Government, but did not obtain it.

All this and much more is to be found in Dr. Parry's book. In his introduction he puts the facts clearly before the reader, and in summing up expresses an opinion that will probably be approved by all his readers. He says: "Had there been in existence at that time a Court of Criminal Appeal, I am convinced it would have reversed the finding of the jury." But the whole book should be read by all those interested in criminal procedure and toxicology.

MEDICAL DIAGNOSIS

The Diagnosis of Internal Diseases is the second volume of Professor LUDOLF KREHL's work on Etiology, Diagnosis, and Treatment.[6] The author presents it as a supplement to the larger German works on diagnosis, and expresses the regret that what was originally meant to deal purely with general considerations has come to be more specialized than is desirable for this object, and yet not specialized enough to be exhaustive. Such a fault is unavoidable in a small textbook which deals with a large subject, and the book suffers from another disadvantage common to its kind—namely, that a work on pure diagnosis divorced from treatment is dealing always with the means to an end, and never with the end itself. Particularly is this the case on account of the author's excellent presentation of his subject from the point of view of applied physiology. He considers the effects of the disease and the general condition of the patient as being rightly of more importance than isolated physical signs, and is thus—at any rate to the reader already learned in medicine—frequently giving hints as to where rational treatment could be applied, but does not, owing to the limitations of his title, lead on into the more practical realms of therapeutics.

Criticism of this book, however, confines itself to criticism of its author's self-imposed limitations. Of its kind it is excellent. Professor Krehl has kept his balance through all the recent rapid advances of medicine. He makes full use of modern diagnostic methods, and yet is old enough and wise enough not to lose sight of the art and skill of the days of pure clinical observation. This combination of "clinical intuition" with a rational and critical use and knowledge of modern science is sufficiently rare in itself to make the book well worth reading, and while it is, perhaps, inspiring rather than directly instructive, there can be none, from third-year student to senior physician, who would not gain something from a perusal of its pages. Unlike most clinical teachers, moreover, Professor Krehl does not preach what he fails to practise himself. Thus the student will not find rules laid down for the examination of a patient which he

[6] *Entstehung, Erkennung und Behandlung innerer Krankheiten.* Von Dr. Ludolf Krehl. Zweiter Band: *Die Erkennung innerer Krankheiten.* Berlin: F. C. W. Vogel. 1931. (Pp. 172. RM. 12.80.)

knows are never followed, but will learn instead that, so long as thoroughness is not neglected, the experienced clinician will vary his examination according to the system most affected. Impossibilities, moreover, are not claimed for clinical methods, and the limitations and difficulties of percussion and auscultation are freely admitted. "Investigate as much as possible, and in any case all that is necessary," is a wise maxim, as is also "to remember it is everything" in the case of the rarer diseases.

The first chapter deals largely with the relation of doctor to patient, and the reader will find here that he has to be something more than a scientist if he would live up to the author's standards. "No one has an excuse not to be able to do a blood count" is an undoubted fact nowadays; but that familiarity with the use of the polygraph and electrocardiograph is not to be expected from all is delightfully acknowledged by the sentence "es ist nicht jeder ein Mackenzie." The later chapters deal with the various systems in order, not merely from the point of view of diagnosis in the sense of giving a name to the disease, but rather in the sense of the "summing up" or "assessment" (Beurteilung) of the patient's condition.

NOTES ON BOOKS

The first of the ten articles in the May number of the *Annals of Medical History*[7] is Dr. A. H. Miller's account of the Pneumatic Institute for the treatment of diseases by inhalation, established by Thomas Beddoes in 1798 at Bristol. The institute was a failure, but it had a noteworthy effect on science by bringing out Humphry Davy, who discovered nitrous oxide gas there in 1799. Beddoes, whose portrait appears on the cover of the number, had been a most successful lecturer on chemistry at Oxford, had inhaled ether until he became unconscious, and was the father of T. L. Beddoes, the poet and author of "Death's Jest-Book." The fiftieth anniversary of the discovery of the malarial parasite was celebrated last year, and Dr. Joseph Franchini's appreciation of Alphonse Laveran, whose portrait is the frontispiece, is published here. Last year also saw the celebration of the tercentenary of the first use of cinchona, and Sir Humphry Rolleston's address on its history, given at the Wellcome Historical Medical Museum, finds a place in this number. Dr. C. A. Elsberg of New York writes on the Edwin Smith surgical papyrus and the diagnosis and treatment of injuries to the skull and spine five thousand years ago, and Hindu medicine and its antiquity are discussed by Dr. P. J. Sarma of Chicago. The interesting subject of the considerable antiquity of pap and panada forms the substance of an article, illustrated by reproductions of pap boats, spoons, and warmers, by Dr. Drake of Toronto. Sketches of medical men, who were pioneers in physics, such as Thomas Young, Helmholtz, and T. J. Seebeck, the discoverer of thermo-electricity, are given by Dr. Podolsky of New York, and Dr. Clemens reproduces medical curiosities culled from historical manuscripts between the reigns of Henry VIII and George IV. The descriptive list of incunabula in the library of the College of Physicians of Philadelphia is continued down to number 297, but there are more to come from this treasure-house.

Thérapeutique Médicale, II: *Aliments Médicaments*[8] is a collection of articles on various "cures" and treatments by dieting. All kinds of regimes are discussed; raw and cooked meat, vegetables, fruits, bread of different types, fish, and so forth. Therapeutics of this type receive, rightly or wrongly, little attention in Britain, at least from orthodox practitioners, and instruction in such methods is absent, or practically absent, from the student's curriculum. On the whole, the attitude adopted in this country is probably the right one. The volume before us is well balanced, and no extravagant claims are put forward; the authors are men of science as well as men of sense; but it is only too easy to see how "cures" of the type described could become nothing more nor less than quackery. A dietary regime always impresses the patient, if only because it interferes with his normal habits and may cause him inconvenience; it can be prescribed by a not over-scrupulous practitioner with a great show of meticulous care and no real knowledge. In certain well-known instances it is the main, sometimes the only, method of treatment; in others, careful dieting may be a useful adjuvant to other treatment, but unfortunately the grains of wheat are so easily lost in the chaff that many practitioners are apt to fight shy of "diet therapy" as a whole. For those who are interested, however, the present volume provides much useful information.

The fourth of the Memoir Series published by the London School of Hygiene and Tropical Medicine is entitled *Anopheline Mosquitos in Southern Rhodesia, 1926–1928*,[9] by Mr. H. S. LEESON. It consists of a report of investigations made during the research on blackwater fever conducted by Dr. G. R. Ross. The anopheline mosquitos of the country are first dealt with in a general way, and then those of a particular area where blackwater fever was endemic.

Professor J. A. LINDSAY of Belfast confesses that for many years he has adopted Lord Morley's maxim that "a book which is worth reading is worth taking notes from." He has now published a little volume comprising a selection of short extracts from a wide range of authors, grouped in some sort according to the ideas expressed. This book, entitled *Among the Thinkers: Leaves from My Note-Books*,[10] forms a pendant to Professor Lindsay's medical axioms, aphorisms, and clinical memoranda, published in 1923.

The second quarterly number for 1931 of *Nosokomeion*,[11] or Quarterly Hospital Review, of which the first volume received notice in the *Journal* of April 11th (p. 630), is devoted to the various aspects of the nursing profession, including its history, international organization, and present status. The international character of the journal is shown by the fact that of the twenty-two articles in this issue three are by British, six by American, eight by German, and one each by French, Dutch, Swiss, Austrian, and Japanese writers. A bibliography of recent literature connected with hospital service is appended.

In a work entitled *Factors in the Sex Life of Twenty-two Hundred Women*,[12] which forms the latest contribution to the publications of the Bureau of Social Hygiene, Dr. KATHERINE B. DAVIS, the general secretary of the Bureau, records the results of an investigation carried out by questionaries addressed to 1,200 married women and 1,200 unmarried women. The former were all of good standing in the community, with no known physical, mental, or moral defect, and of sufficient intelligence and education to understand the set of questions addressed them, while the latter were exclusively college graduates. The questions, the answers to which are arranged in tabular form, dealt with the use of contraceptives, the frequency of conjugal relations, pre-matrimonial sex instruction, sexual desire, orgasm, masturbation, and homosexuality, which in the writer's opinion is much more prevalent than is generally supposed.

SATURDAY, JUNE 27th, 1931

WELFARE OF THE BLIND

There is evidence that the toll of the blind in England and Wales is increasing. The last official record was made in 1929, when there were 53,727 registered blind persons; since then the registers have indicated an increase to 56,853. These figures are given in the ninth report to the Minister of Health by the Advisory Committee on the Welfare of the Blind.[1] Commenting on them, the report suggests that the figures do not indicate an actual increase in the number of the blind, but only their more effective registration. Nevertheless, some concern is felt that such a large proportion of the general population should have sight so bad as to render them "too blind to perform work for which eyesight is essential." Much work has been done for the prevention of blindness, but more should be done. The matter is under study by a committee of societies of the blind. Under Section 66 of the Public Health Act of 1925, local authorities have ample powers to make arrangements for the prevention of blindness. Undoubtedly one of the reasons for the increase of the number of the known blind is the benefits that are offered—schemes of training, assisted employment, and pensions. In 1921 the number in receipt of pensions was 7,826; last year it was 19,048. Certain anomalies have been found in the working of the provision of pensions for the aged blind. It is possible for a blind person aged 65 to receive £1 a week; at the age of 75 there is an automatic drop to ten shillings. Suggestions are made for meeting this difficulty.

It is evident that the committee views with some anxiety the working of the new Local Government Act. As from April, 1930, the detailed supervision which the Ministry of Health exercised through its inspectors over the voluntary blind societies came to an end, and this duty devolved upon the local councils. The work of the inspectors of the Ministry was of great value in encouraging the local authorities, and particularly as a unifying influence. Their work is lost just as it appeared to begin to be of effect. There is also danger that the technical knowledge they could supply may be lacking to the local authorities. The difficulty is in the way of being met by the action of a considerable number of local authorities in the North of England; these have authorized one of the associations for the blind to appoint an experienced officer as regional supervisor, whose duty will be to inspect the work of voluntary associations, and to submit reports to the appropriate authorities. In this way there will be expert advice available, and some unity of action. The scheme is one that might be copied elsewhere with advantage to all concerned. Reference is made to the recent circular letter issued by the Minister, in which he drew the attention of local authorities to "the desirability of making arrangements for securing that, before a person's name is added to the register of the blind, he is examined by a medical practitioner *with special experience in ophthalmology*, and by him certified to be blind within the meaning of the Blind Persons Act." It is added that there should be little difficulty in making such arrangements in a county borough, but there may be more difficulty in a county which is largely rural in character. In some counties it is noted that all persons claiming to be blind are examined by officers of the school medical service with special experience in ophthalmology.

In connexion with this report it is convenient to review the report of a deputation of English musicians and tuners to France and Germany undertaken at the instance of the National Union of Professional and Industrial Blind of Great Britain and Ireland.[2] The deputation numbered seven; their object was technical, but they recorded more general observations. Among their findings are the following: "In almost every essential service our [that is, the English] system of caring for the blind is far superior to the existing arrangements either in France or Germany, whilst our knowledge of conditions obtaining in Italy leads us to conclude that welfare work there on behalf of the blind is even less satisfactory. In no European State other that Britain is voluntary effort so successful and so conspicuous a feature of national life, and in none is this effort applied with such skill and administrative efficiency." Comment is made upon the figures of the blind published in the League of Nations Report for 1929. The German census of 1925 showed that there were then 58 blind persons per 100,000 of the population, whereas in 1927 there were 119 in England and Wales. The deputation decline to believe that the incidence of blindness is twice as great in this country as in Germany, in view of the fact that preventive work is not more advanced in Germany than with us. If it be assumed that the English figures are not appreciably inflated by malingering, it would appear that those for Germany do not reflect the true position. This is mainly owing to the greater severity of definition, and to the lack of inducement for the aged, and for doubtful cases, to come forward. In Germany a person must be considered blind whose sight is not more than 1/25 of the normal; in this country it is reckoned as 1/10 normal vision with glasses.

The Disablement Law of Germany compels the employment in industry of certain percentages of war-disabled men. This German experiment clearly indicates that many so-called unemployed blind could be profitably employed in factories. A few experiments on the same lines have been made in this country. There has been some opposition from organized labour. It is said that this has almost entirely subsided, because the

[2] Report of Deputation of Musicians and Tuners to France and Germany. The National Union of Professional and Industrial Blind of Great Britain and Ireland. (1s.)

blind have been able to prove their capacity to work satisfactorily. It is suggested that there is room for extension of the employment of the blind in general work, and that Government and municipal undertakings might set the example. Comment is made on the absence of training of blind masseurs in Germany and the poorness of the training given in France. The system of the National Institute for the Blind in this country has been so effective that 90 per cent. of those trained are entirely self-supporting.

ASPECTS OF THE CANCER PROBLEM

It is doubtful whether any theory of the nature of cancer which would be considered exempt from serious criticism, in one respect or another, can be formulated at present. Attempts in this direction can only be regarded as partial, and helpful only in so far as they suggest lines of inquiry or serve to bring the innumerable isolated observations on record under a single conception. Professor Scherber's recent book, "Contributions to the Solution of the Cancer Problem,"[1] is an attempt of this kind; it brings together a vast number of alleged and established facts in a manner that renders their possible interdependence comprehensible to those who are not very well versed in cancer research.

The cancer problem has broadened out considerably in the last few years. Formerly it was a question of the discovery of the germ or other specific proximate cause of cancer; it is now recognized that a special constitutional factor has to be taken into consideration as well. Several facts point to the existence of such a factor, among which may be mentioned the increased tendency to the disease as age advances, and the greater susceptibility of some organs in comparison with others. An actual hereditary tendency is difficult to prove in man, but it probably exists in some degree, and it has been produced in animals by suitable crossing, so as to become manifest on simple irritation in 100 per cent. of the cases (Slye). In instances such as these, in which the nature of the irritant eliciting the outbreak of the cancer appears to be a matter of indifference, the existence of a disposition to the disease is clearly the important factor—it may almost be said to be the sole factor. There are, however, cases of a different type, in which the irritant itself appears to be specific—that is, it is not a matter of indifference what irritant is employed. Of this type are many occupational cancers and a large proportion of the experimental cancers. In some instances the exact chemical constitution of the irritant has been established; the cancer-producing substance in tar, for example, which has been studied by Kennaway and others, is an unsaturated hydrocarbon related to benzol in chemical constitution (Vaubel). Now it is a significant fact that these specific irritants do not, like infections, produce a practically immediate effect; a more or less prolonged "latent period" must elapse before the cancer develops. This period is prolonged for years in some instances, and it is not necessarily coextensive with the period of application of the irritant, for the action of the latter may be suspended, leaving merely an induced disposition to the disease, manifested in some or all of the cases concerned. It would appear to be a fair deduction from this fact, that the specific action of these irritants is not so much the production of cancer as the production of a disposition to cancer, the irritant, as Scherber suggests, acting as a substitute for heredity in creating a general or local susceptibility to the disease. If a similar line of reasoning is applicable to spontaneous cancer generally, it should be possible to detect a production, in the body, of specific substances having this property.

In this connexion the researches of Kaminer and Freund are suggestive. These observers have shown that there exists normally, in the intestines of mice, a saturated fatty acid, formed by the action of the normal bacteria on ingested fat, and possessing anti-cancerous properties; in predisposed animals this is replaced by an unsaturated fatty acid, produced, it is believed, by an altered intestinal flora, and they suggest that this compound, passing into the circulation, may possibly be concerned in the production of cancer. A similar substitution of an unsaturated, in place of a saturated, compound has also been shown to occur in precancerous tissue. It is not suggested that an abnormal intestinal flora is the sole means by which a disposition to spontaneous cancer may be induced. The whole field of metabolism has to be explored; but it may be taken as proved that chemical changes in the organism have an important influence in the production of cancer, and it is possible that these changes may ultimately be found to be amenable to control.

KITASATO

Baron Shibasaburo Kitasato represented an era both to the East and the West. He was one of the early group of able young Japanese who came to explore Western civilization and science in 1885. He worked under Koch's inspiration from 1885 to 1891, and to the last venerated his master's memory; throughout the war and to the end of his life he tended reverently the shrine erected near his institute to Koch's memory. In the West, Kitasato will be chiefly remembered for his part in the work with Koch and later with Behring, culminating on December 4th, 1890, in what Professor Bulloch fitly calls "the brief but epoch-making paper" by Behring and Kitasato, which established for the tetanus bacillus the three fundamental facts—that is, that a soluble toxin is produced, that animals continuously injected therewith develop a neutralizing substance called "antitoxin," and that this antitoxin is specific. Behring's paper published a week later confirmed these three findings for diphtheria. Two years later Kitasato, returning to Japan with gleanings of European bacteriology and his own achievements, became director of the Imperial Japanese Institute for the Study of Infectious Diseases. In 1894, when the

dreaded pandemic of plague reached Hong-Kong, Kitasato and Aoyama went to investigate it. Landing on June 12th, Kitasato had by June 14th seen the specific bacillus in films made after a necropsy. It is said that he immediately cabled to Koch that he had seen the specific bacillus in films. In reply to Koch's answering cable, asking if he had cultivated the bacillus, he was able in a few days to report success. The preliminary notice was published in July in Hong-Kong. Yersin arrived in Hong-Kong within a week of the Japanese mission, and independently discovered what is now accepted as the *Bacillus pestis*. Kitasato's work and researches naturally dealt with many diseases. He investigated epidemics of plague in North-Eastern Asia, and in 1909 read a paper on tuberculosis at an international congress held in Europe. In 1915 he left the Government Institute and established his private laboratories in Tokio, where he worked for many years. It is understood that these laboratories were highly successful and provided a liberal competence.

THE WASSERMANN REACTION

The Wassermann reaction is now such a familiar test that it is perhaps hard for the modern student to realize that once upon a time there was no such thing. The discovery of this test, like most scientific discoveries, was not the result of a sudden inspiration on the part of one man, but the outcome of patient experiment by a number of bacteriologists, culminating in the publication of the researches of Wassermann, Neisser, and Bruck in 1906. In their recent memorandum,[1] S. A. Mann and F. Partner give a detailed description of the technique in use at the central pathological laboratory of the London county mental hospitals, and a brief historical summary of the work which ultimately led to the discovery of the Wassermann reaction. The starting-point of the series of investigations leading to the formulation of a test which, without exaggeration, can be said to have revolutionized medicine, was "Pfeiffer's phenomenon." Pfeiffer found that the cholera vibrio, when injected into the peritoneal cavity of a guinea-pig immunized against cholera, lost its motility, became granular, swelled, and finally disappeared. It was subsequently shown by Metchnikoff and Bordet that the phenomenon of bacteriolysis could occur *in vitro* if the cholera vibrio was brought into contact with heated immune serum in the presence of normal serum or fresh peritoneal fluid. The observation that bacteriolysis did not occur if the normal serum added was stale, or had been heated to 56° C., led to the isolation of the three components in the bacteriolytic reaction—the invading organism or antigen, the antibody, and complement. The reactions were found to be specific in character, with the drawback, however, that they could be studied only if the bacteriolysis was visible. This difficulty was overcome by the use of haemolytic systems and the discovery of the Bordet-Gengou phenomenon. It was found by Bordet that, if the red blood cells of one animal were injected into an animal of a different species, antibodies were produced in the blood of the second animal which would haemolyse the red cells of the first. Such haemolysis could be demonstrated *in vitro*. These haemolytic reactions were shown to be specific, necessitating the presence of antigen (the red blood cell of the first animal), of antibody (haemolysin of the second animal), and of complement. The presence of complement, therefore, could be detected by the use of such haemolytic systems (haemolysis not taking place in the absence of complement); and Bordet and Gengou showed that in the interaction between antigen, complement, and antibody, complement is deviated, absorbed, and lost to the systems. By these means, then, the presence of specific antibodies in the blood could be shown either by observation of bacteriolysis of the specific antigen, or by demonstration of the deviation or fixation of complement, the haemolytic system serving as an indicator. The researches of Wassermann and Bruck, of Marie and Levaditi, showed that extracts of bacteria or extracts of tissues infected with bacteria were as good specific antigens as the bacteria themselves. Moreover, it was shown later that the *Treponema pallidum* is the least suitable of antigens for demonstrating the presence of antibodies in the blood of persons infected with syphilis. Having discovered that an extract of the liver of a syphilitic foetus could serve as a specific antigen for syphilis, Wassermann, Neisser, and Bruck, using Bordet and Gengou's method of demonstrating specific immune bodies, evolved the complement-fixation test for syphilis and published their results in 1906, a year after the discovery of the spirochaete by Schaudinn and Hoffmann. These researches were carried out on the theory that the reactions involved were specific in nature, a theory which later had to be abandoned when it was shown that emulsions of lecithin, or mixtures of lecithin and cholesterol, could serve equally well as antigens in the Wassermann reaction. At the present day, cholesterol mixed with lecithin obtained from the human heart is used as the antigen, and a test which is strictly non-specific in nature is made to establish the presence of the specific infection of syphilis, although the work done in the evolution of the test was based on the theory that the interaction between antibody and antigen was of a truly specific character. The theories may change, but the facts remain the same; and the Wassermann test obeys the chief, perhaps the most important, criterion in these matters—it works.

[1] Memorandum on the Wassermann Reaction in Mental Hospital Practice. By S. A. Mann, D.Sc., F.I.C., and F. Partner. Published by the London County Council. 1931. (9d.)

THE NATIONAL PHYSICAL LABORATORY

Two pieces of investigation stand out prominently in the National Physical Laboratory's report for the year 1930.[1] One of these is the testing of large quantities of radium, including the purchases of the National Radium Trust. The number of radium preparations which passed through the laboratory last year was 5,600, as against only 343 two years ago. National radium, aggregating some 20 grams, of a value of nearly a quarter of a million pounds, and distributed in some thousands of containers, has been passed through an elaborate system of testing and record-taking. The containers are of about twenty different types, of various nominal contents, lengths, and diameters, and the "life-history" of every one of them is indexed at the laboratory, like criminal finger-prints at Scotland Yard. These containers are first of all grouped in batches, each batch containing five or ten

[1] H.M. Stationery Office. (12s. 6d. net.)

needles or tubes. The batch is then tested for any leakage of radium emanation, and if such leakage is discovered the faulty container is identified and isolated. Containers which pass the leakage test are then tested in groups for radium content by gamma-ray comparison with laboratory standards, calibrated in terms of the British radium standard, and the results are expressed in milligrams of radium element in radio-active equilibrium. An interval of twenty days separates the two measurements which are made for this purpose, and if the results are in agreement it is assumed that equilibrium has been obtained. Even when the gamma-ray measurements have been taken, they indicate only the effective, not the actual, radium content, and a further measurement is made with a correction for the thickness of the walls of the container. The laboratory is responsible, also, for distributing radium to the several centres. On instruction from the Radium Commission, the laboratory sorts out and checks the various types of containers required, and its representative travels to the centre with the radium which has been requisitioned. The other work of special interest, about which, however, no particular conclusion has yet been reached, is a large-scale investigation on noise. Progress has been made in the use and standardization of noise-measuring instruments, but recommendations for amelioration of this evil are yet to seek. The motor-horn has been the subject of special investigation at the instance of the Ministry of Transport; but all we can gather from the report is that a horn which is not objectionable when correctly used can become a great nuisance as a result of improper adjustment, that sheer loudness is the primary consideration in determining the annoyance, and that it is possible that the occurrence of strong notes unrelated to the general harmonic series, and the manner in which the horn commences its note, may be subsidiary causes of stridency; a much larger range of instruments will have to be studied before these points can be elucidated. The laboratory has also been investigating the noise of aircraft. Such factors as engine position, cabin wall construction, and gearing in their effect on the noisiness of machines have been studied, and experiments have been made on the transmission of sound through light material suitable for cabin walls. Further work has been carried out on the acoustics of buildings, including the Ulster Parliament House and the Salle Electorale at Geneva, where the Assembly of the League of Nations now sits; this work consists in the correction of excessive reverberation and the tracing of echo effects. There is much else of interest in this report, which embraces the year's work of seven departments and some six hundred workers of all ranks. Mention is made of the fact that assistance has been given to the British Pharmacopoeia Commission in evolving a colour specification for the antimony chloride test for cod-liver oil, and another department of the laboratory has been co-operating with the Commission with a view to devising tests for durability of the glass ampoules used for medical purposes. The annual inspection of the laboratory and its departments took place on the afternoon of June 23rd, when visitors were received by Sir Frederick Hopkins, P.R.S., Sir Richard Glazebrook, and the director, Sir Joseph Petavel, and many experiments and pieces of apparatus were shown by the staff.

LIMITATION OF DANGEROUS DRUGS

The International Conference on the Limitation of Traffic in Dangerous Drugs, referred to in the *Journal* of May 23rd (p. 905), was opened at Geneva on May 27th. Delegates from fifty-one States were in attendance, and Senator Louis de Brouckère of Belgium was elected to the chair. In his opening address the president emphasized the complexity of the task before the conference, and recognized that while there was general agreement on the principle of restricting the manufacture of drugs to such as are required for medicinal purposes there was much difference of opinion as to the best means of realizing it. Doubts had, he said, been expressed as to the efficacy of the Geneva Convention of 1925, and it was now incumbent upon them to devise an effective plan for securing that limitation of production of dangerous drugs to medical and legitimate requirements which was contemplated by the Hague Opium Convention of 1912. The conference is assisted by three experts: Professor von Knaffl-Lenz of Vienna, Professor Tiffenau of Paris, and Dr. P. Wolff of Berlin, while Mr. Lyall, chairman of the Central Opium Control Board, attends in an advisory capacity. A sharp division of opinion soon became evident at a meeting of the Committee on Limitation last Friday, when the British delegate, Sir Malcolm Delevingne, despaired of framing an agreed form of words which would combine his proposals with those put forward by the French and Japanese delegates. By 14 votes to 2, with 6 abstentions, the Franco-Japanese proposal was adopted as a basis for discussion. This did not incorporate the quota system, propounded at the London Conference of last November, whereby agreed proportions of the world's requirements were to be allotted to the several manufacturing countries. It contemplated that no country should manufacture more than its annual estimate for medical requirements (1) for domestic use, (2) for conversion, and (3) for export; the last-named to be based on firm orders against import certificates duly authenticated. Proposals were also made for the prohibition of the manufacture of heroin, but these did not receive unanimous support. It would appear that the initiative at present does not lie with the British Government; on its behalf it was urged that support could not be accorded to any scheme which did not give to the medical profession the opportunity of buying what it needed wherever it considered best and in the form dictated by medical experience.

A SURVEY OF DISEASE IN SIERRA LEONE

Sierra Leone has been fortunate in possessing, at Freetown, the Sir Alfred Lewis Jones laboratory for research into the tropical diseases of Africa. Many valuable contributions to science have originated there; the latest of these is a detailed report on a survey of human diseases in the Protectorate.[1] The survey was made in two halves: the first is concerned with the Northern Province, where the principal clinical diseases are malaria, gonorrhoea, and yaws; the second deals with the Central and Southern Provinces, where yaws is less frequent, but other conditions, such as schistosomiasis, increase in importance. In both regions

[1] Report on a Survey of Human Diseases in the Protectorate of Sierra Leone. By Dr. D. B. Blacklock. Printed by the Government Printer, Freetown. 1930.

dermatitis of various kinds is common, while leprosy is much commoner in the north. Sleeping sickness *seems to be uncommon. The usual helminthic infections* occur in the country. When this report is compared with that recently published by Professor R. P. Strong, and discussed in our issue of April 11th, (p. 635), it is seen that in general the same diseases appear and in much the same order. The situation is, however, much more favourable than in Liberia. Dr. Blacklock considers that the state of general health might be improved by making use of the tribal system, in addition, of course, to the medical department and the mission workers. Chiefs should know something of hygiene ; and education in the schools should include instruction in diet, cleanliness, and sanitation, which would in due course be applied practically.

MANSON HOUSE

On June 24th the Royal Society of Tropical Medicine and Hygiene, whose first president was Sir Patrick Manson, moved into its new home, Manson House, 26, Portland Place. At present only the office and library are ready for occupation, but the other necessary alterations will be carried out as soon as possible, and a small hall for meetings is being erected at the rear of the building. As a result of the appeal issued last year by the president, Dr. G. Carmichael Low, and Sir Austen Chamberlain, nearly £12,000 has been raised, but a further £17,000 is required to equip Manson House as a suitable headquarters where Fellows when on leave or visiting England can meet and discuss with those at home the problems of tropical medicine and hygiene. The society includes workers in tropical medicine in all parts of the world, with representatives of all the well-known centres and schools of tropical medicine. The Prince of Wales and the Duke of York have sent contributions to the fund, and the council hopes that many others will wish to share in this memorial to one of the great benefactors of our race. Donations will be gratefully acknowledged by the president if sent to him at Manson House, 26, Portland Place, W.1.

SOUTH AFRICAN MEDICAL CONGRESS

The fourth annual scientific meeting of the Medical Association of South Africa (B.M.A.), which represents the twenty-fifth South African Medical Congress, will be held in Johannesburg from September 14th to 19th, under the presidency of Dr. Francis Napier ; an even more extensive programme than in previous years has been planned. After the opening ceremony and the presidential address on the first afternoon Professor C. F. M. Saint will deliver the Popular Lecture ; he will speak on cancer, and the audience will be allowed to ask questions. As in previous years there will be five main scientific Sections: medicine, surgery, obstetrics and gynaecology, public health, and special subjects. The last group is to be subdivided on this occasion into ophthalmology ; otology and laryngology ; dermatology, venereology, radiology, and physiotherapy ; anaesthetics ; paediatrics ; and psychiatry and neurology. Plenary sessions will be held in each of the five principal Sections, the subjects for discussion being constipation ; the diagnosis and treatment of acute appendicitis ; medical attendance in pregnancy, labour, and the puerperium ; pure milk supply, with special *reference to legislation ; and hysterical phenomena.* Numerous attractive social functions and excursions are being arranged, and visits are to be paid to such local scientific centres of interest as the South African Institute of Medical Research, the Johannesburg General Hospital, the Government artificial limb factory, and the mines. The registration fee is £2 2s. for members of the Association, and £5 5s. for non-members. The organizing secretary is Professor J. J. Levin, and the medical secretary for the congress is Dr. B. G. Melle ; inquiries should be addressed to them at the Medical School, Hospital Street, Johannesburg.

INTERNATIONAL SOCIETY OF SURGERY

The ninth Congress of the International Society of Surgery will be held in Madrid from March 15th to 18th, 1932, under the presidency of Professor de Quervain of Berne, with Professor Recasens of Madrid as vice-president. Delegates from Austria, Germany, and Hungary will again attend this congress. The scientific programme includes discussions on the diagnosis and treatment of intraspinal tumours, non-tuberculous pulmonary suppuration, the surgery of the oesophagus, and recent progress in the various forms of surgical anaesthesia. It is proposed to arrange a tour starting from Irun on March 13th, and visiting Madrid for the congress, thence proceeding to Toledo, Seville, Cordova, Granada, Valencia, and Barcelona, with an excursion from the last-named to Monserrat. The inclusive cost of this tour will be just under 4,000 francs ; inquiries should be addressed to L'Agence Belge de la Compagnie Française du Tourisme, 29, Boulevard Adolphe Max, Brussels. Further information about the congress will be supplied in due course by the general secretary, Dr. L. Mayer, 72, Rue de la Loi, Brussels.

Dr. W. W. Jameson, professor of public health in the London School of Hygiene and Tropical Medicine, has been appointed dean of the School, in succession to the late director, Sir Andrew Balfour.

We regret to announce the death of Dr. John Carswell, formerly Medical Commissioner to the General Board of Control, Scotland, and a pioneer in the treatment of mental disorder on general hospital lines.

Our *Supplement* this week includes the Supplementary Report of Council for 1930–31 ; a letter by Dr. H. H. Dale, F.R.S., on medical patents ; and an abstract of Dr. Goodbody's presidential address to the Metropolitan Counties Branch. Next week's *Supplement* will be devoted to the work and problems of the Colonial Medical Services, using that term in its widest sense.

The annual dinner of the British Medical Association will take place at the Grand Hotel, Eastbourne, on Thursday, July 23rd, at 7.30 p.m. As the accommodation is limited, it is desirable that members wishing to have tickets reserved should notify the Honorary Secretary, Eastbourne Meeting, Avenue House, Eastbourne, at the earliest possible date. Tickets will be allotted strictly in order of application.

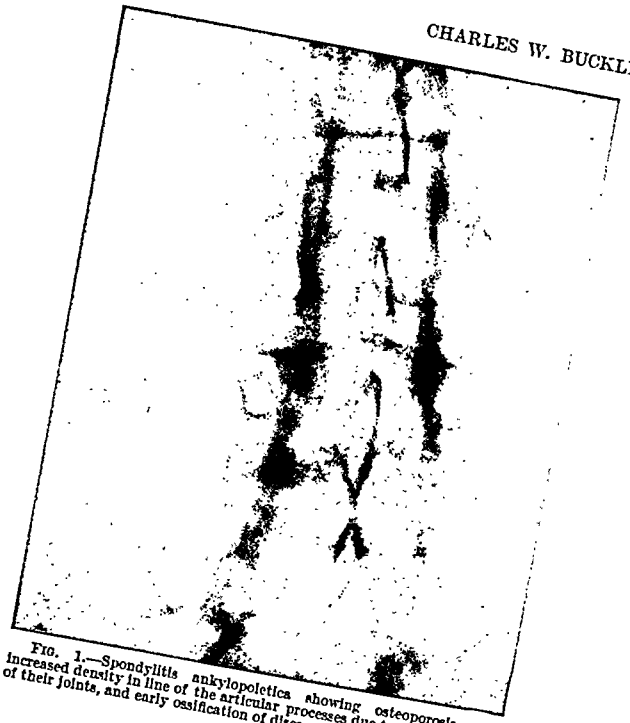

FIG. 1.—Spondylitis ankylopoietica showing osteoporosis with increased density in line of the articular processes due to the ossification of their joints, and early ossification of discs.

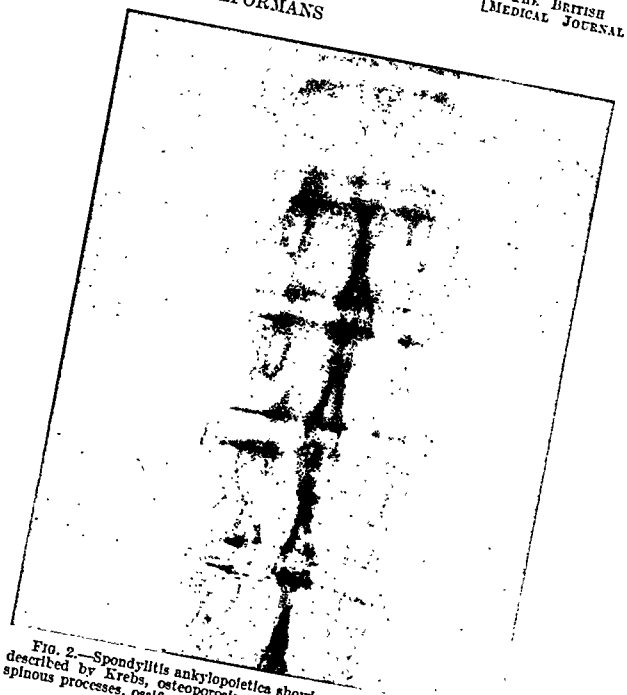

FIG. 2.—Spondylitis ankylopoietica showing bamboo-like appearance described by Krebs, osteoporosis and increase of density in lines of spinous processes, ossification of discs, and of costo-vertebral joints.

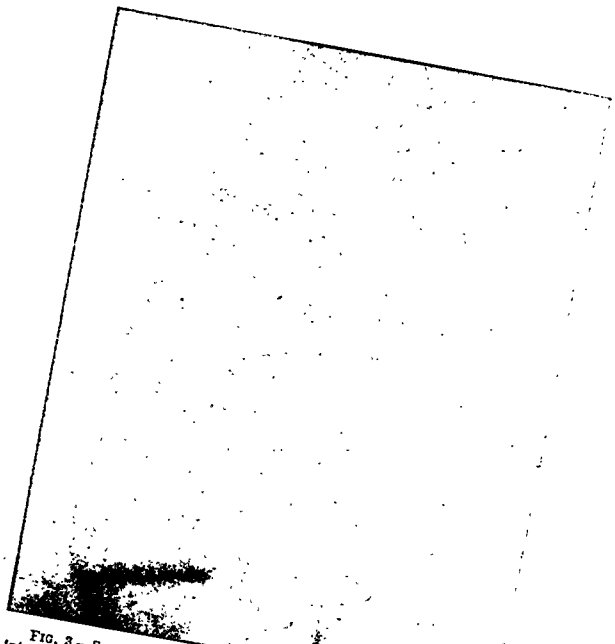

FIG. 3.—Spondylitis ankylopoietica showing ossification of edges of intervertebral discs giving rise to appearance of ossification of anterior common ligament.

FIG. 4.—Spondylitis ankylopoietica in cervical region showing ossification of anterior common ligament and intervertebral discs, ligaments, and articulations. Bechterew type.

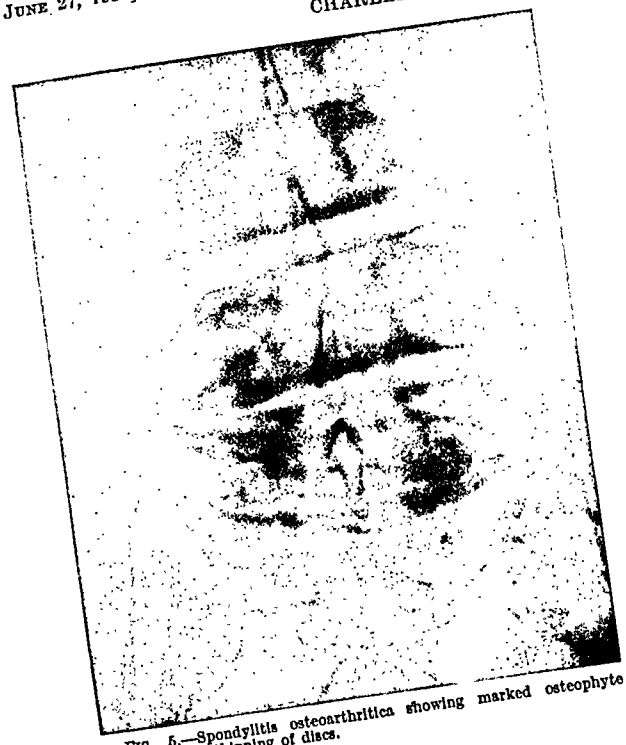

FIG. 5.—Spondylitis osteoarthritica showing marked osteophyte formation and thinning of discs.

FIG. 6.—Tubercular disease of the spine in a patient aged 59, a condition liable to be confused with spondylitis.

H. E. SEILER AND MARY D. GILMOUR: PULMONARY ASBESTOSIS

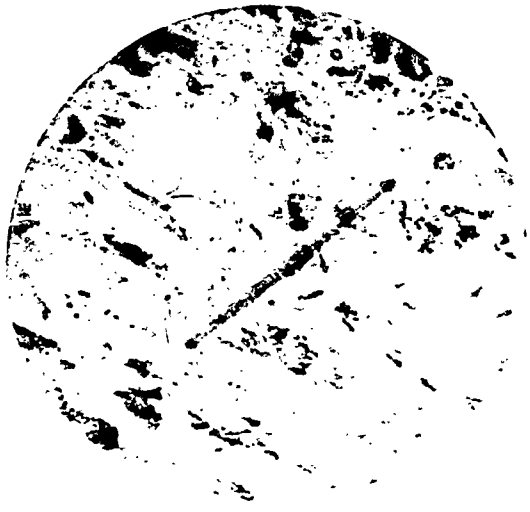

FIG. 1.—Asbestosis body and phagocytes containing granular pigment in fibrous lung.

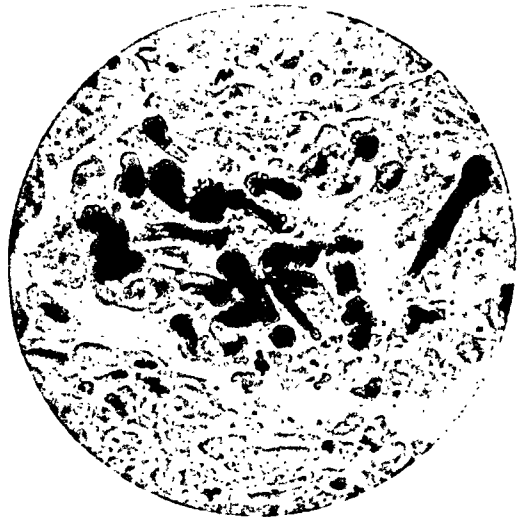

FIG. 2.—Asbestosis bodies showing discoid arrangement and globular ends.

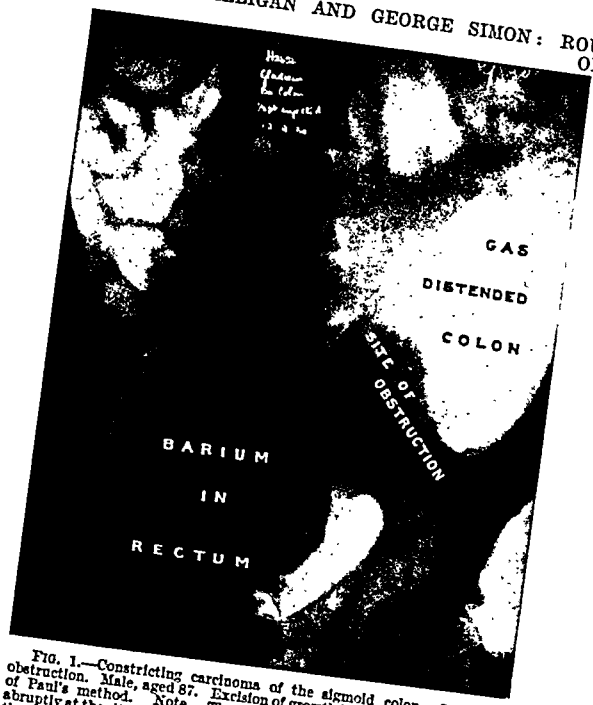

FIG. 1.—Constricting carcinoma of the sigmoid colon. Sub-acute obstruction. Male, aged 87. Excision of growth by Devine's modification of Paul's method. Note.—The gas-ballooned proximal sigmoid ends abruptly at the site of obstruction. Distinctness of the site of obstruction, thereby produced, equals that indicated by barium and in the rectum.

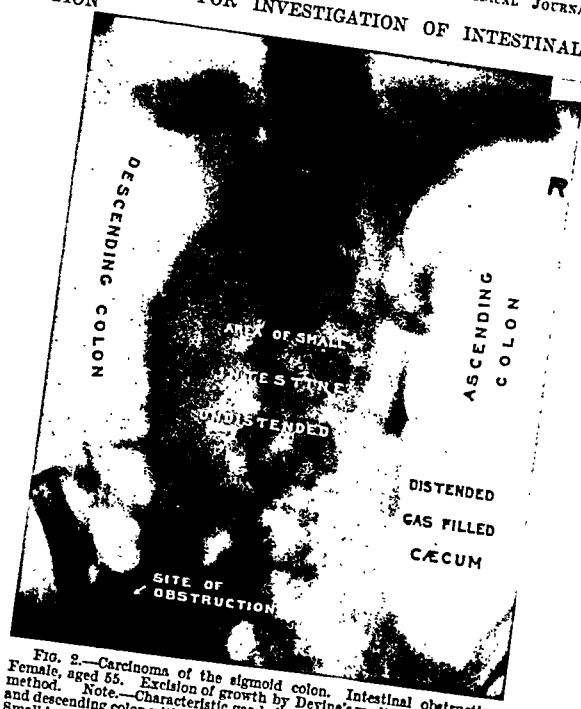

FIG. 2.—Carcinoma of the sigmoid colon. Intestinal obstruction. Female, aged 55. Excision of growth by Devine's modification of Paul's method. Note.—Characteristic gas ballooning of the cæcum, ascending and descending colon with abrupt ending localizing the site of obstruction. Small intestine is undilated and so does not show in the film.

FIG. 3.—Fibrous obstructing stricture of the sigmoid colon in a very corpulent female. Note.—Enormous distension of the cæcum which reaches across the midline showing main incidence of obstructive dilatation. The dilated transverse colon is seen in the upper part of the film, and therefore indicates site of obstruction below this point. Another film of this patient, not exhibited, revealed the actual site of obstruction in the sigmoid colon, suggesting that if the first film does not reveal the site of obstruction very clearly another taken only a few minutes later may do so.

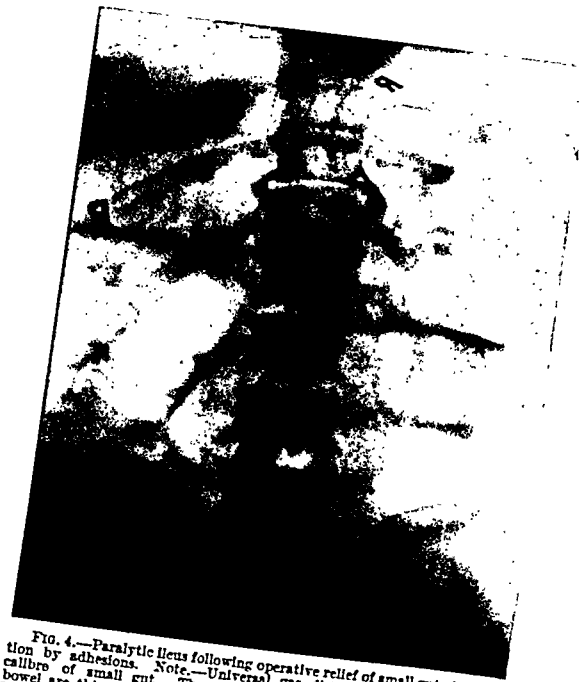

FIG. 4.—Paralytic ileus following operative relief of small gut obstruction by adhesions. Note.—Universal gas distension and increase in calibre of small gut. The transverse striations in distended small bowel are thinner and more closely spaced than in dilated large gut. Furthermore, adjacent walls of distended small gut pressed together by gas show as striking dark bands running obliquely or transversely across the abdomen, contrasting with the clear gas-filled translucent areas between.

E. T. C. MILLIGAN AND GEORGE SIMON: ROUTINE RADIOGRAMS FOR INVESTIGATION OF INTESTINAL OBSTRUCTION

FIG. 5.—Strangulated femoral hernia. Female, aged 75; operation; recovery. Radiogram shows very early localized stage of dilated small intestine in small gut obstruction. The colon is undistended.

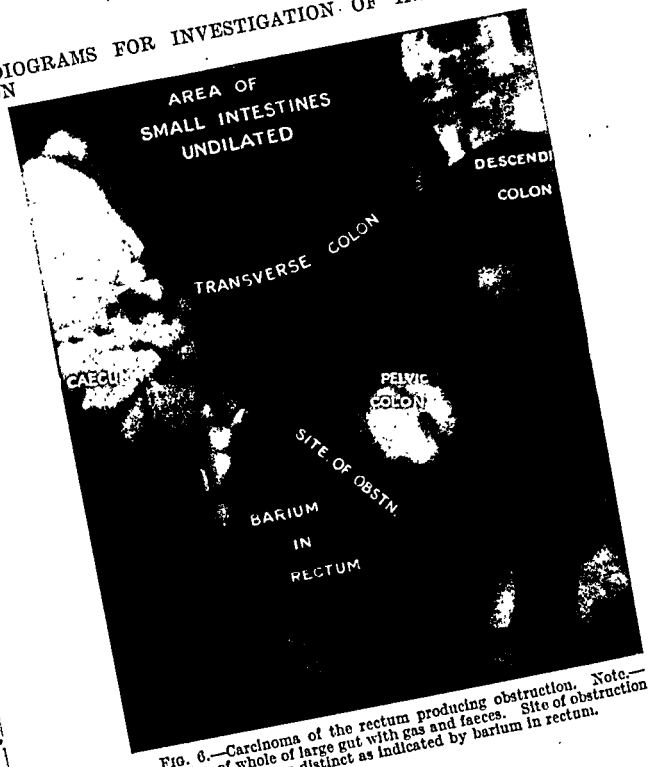

FIG. 6.—Carcinoma of the rectum producing obstruction. Note.—Distension of whole of large gut with gas and faeces. Site of obstruction indicated by gas is as distinct as indicated by barium in rectum.

H. HILTON STEWART AND J. H. BIGGART: ACUTE BRONCHIOLECTASIS

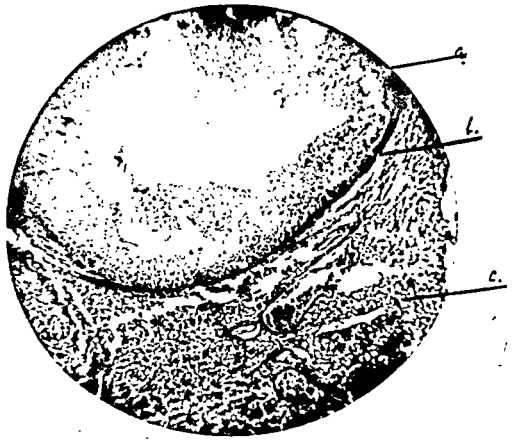

FIG. 1.—Low power view of bronchiolectatic cavity; (*a*) lumen of bronchiole filled with purulent exudate; (*b*) remnants of bronchiolitic wall; (*c*) surrounding lung alveoli partially collapsed and pneumonic.

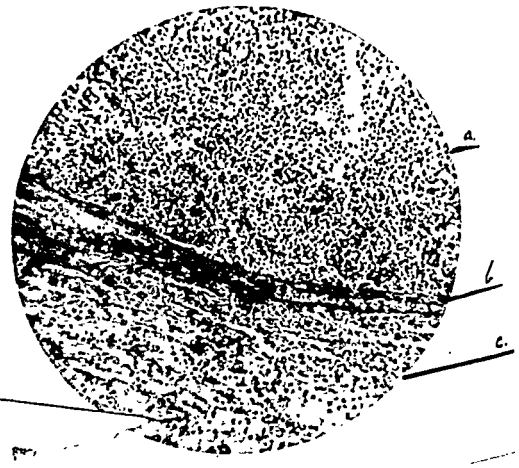

FIG. 2.—High power view of wall of bronchiole; (*a*) the exudate is composed of polymorphonuclears; (*b*) the congested wall of the bronchiole from which the epithelium has disappeared; (*c*) the partially collapsed alveoli.

SIR CHARLES HASTINGS MEMORIAL FUND

To celebrate the Centenary of the British Medical Association the Council has decided to open a fund for the purpose of establishing a permanent memorial to the memory of its founder, Sir Charles Hastings. It has been decided that the memorial shall take the form of a stained-glass window in the cathedral at Worcester, a city with which Charles Hastings was very intimately associated all his life; the placing of a tablet on the house in Worcester in which he practised; and the restoration and permanent upkeep of his grave in the Astwood Cemetery, Worcester. Any balance left over after these objects have been fulfilled will be given to the Sir Charles Hastings Fund, which was endowed in 1925 with a permanent income of about £70 a year by the generosity of the late Lieut.-Colonel J. W. F. Rait, I.M.S.(ret.), a former member of the Council of the Association, and of Mrs. Rait. This fund is controlled by a small body of trustees, who have power to distribute the income for the benefit of individual members of the profession or their dependants in any way that the trustees may think fit. The fund has proved exceedingly useful in cases which do not come within the ordinary scope of the Royal Medical Benevolent Fund, and in cases in which there is very urgent need for help. Subscriptions to the memorial fund are limited to £1 1s., and a list is appended of those members of Council and others who have already contributed.

The Council appeals with confidence to members of the Association all over the world to contribute to this fund. The opening ceremony of the Centenary Meeting will be a pilgrimage to Worcester on Sunday, July 24th, 1932, when the unveiling of the memorial window and plaque will form an important part of the ceremonies of the day, which are already being anticipated with eagerness by the city authorities and by the public.

Members are requested to send their contributions without delay to the Financial Secretary, British Medical Association House, Tavistock Square, London, W.C.1, and cheques should be made payable to the "Sir Charles Hastings Memorial Fund." They will be acknowledged in the columns of the *Journal*.

First List of Contributions

Dr. G. A. Allan
Mr. J. Armstrong
Dr. F. J. Baildon
Dr. Harold S. Beadles
Professor R. J. A. Berry
Sir Robert Bolam
Dr. J. W. Bone
Dr. H. B. Brackenbury
Dr. H. C. Bristowe

MORTALITY FROM TUBERCULOSIS

REPORT BY THE HEALTH SECTION OF THE LEAGUE OF NATIONS

The February and March reports of the Health Section of the Secretariat of the League of Nations contained a comprehensive statistical review of the mortality from tuberculosis in various countries during the last fifty to eighty years. Figures have been collected and arranged to facilitate the testing of current theories relating to the epidemiology of this disease. There have thus been brought to light notable changes in the mortality rates, and the existence of definite trends in that mortality as regards the populations of cities and rural areas, and at various age periods in both sexes; it has even been possible to discern the occurrence of changes in those trends.

FALLACIES IN THE STATISTICAL CRITERIA

Attention is first called to certain imperfections and shortcomings in the statistics relating to tuberculosis, and to the danger of drawing inferences from the figures without critical examination and due correcting, it being impossible to accept at their face value all the mortality figures, and still less those relating to tuberculosis morbidity. Some are grossly deceptive, and practically all are inaccurate, though in varying degrees in different countries. Thus, as regards tuberculosis morbidity, this disease, even in its pulmonary form, is not notifiable in Austria, Belgium, the Netherlands, Sweden, and parts of Germany. In France, where notification is optional only, its inadequacy is evidenced by the fact that the number of pulmonary cases notified in 1927 was 25,666, while the number of new cases which came under the care of the dispensaries was 43,714, and the number of deaths attributed to pulmonary tuberculosis was 60,679. Since this disease does not cause more than about 10 per cent. of all deaths it is obviously a curable condition; the number of cases reported should, therefore, far exceed the number of deaths ascribed to it. A table is included showing that this is very far from being generally the case. In some countries two cases of tuberculosis are reported for each death, in others only one, while elsewhere two deaths have been registered for each case reported!

It is clear, moreover, that the age distribution of tuberculosis has distinctly altered during the last fifty years in many civilized countries, and that the relative incidence of the various clinical symptoms has also changed. In England, for example, the acute forms are much rarer than they used to be, while the chronic ulcerative and fibrous types are now more common. This has been the case generally in civilized countries, and especially in the larger cities. In short, morbidity has declined less than mortality, except in primitive and agricultural countries, where tuberculosis is still advancing, and where the ratio of illness to mortality is lower than in urbanized countries.

Although mortality figures yield a better picture of the tuberculosis situation in any given country than do case-notifications, errors are introduced by the reluctance of some medical practitioners to impose the stigma of tuberculosis, and their notifying the condition as bronchitis or broncho-pneumonia. If the tuberculosis rate falls co incidentally with the rates for the other two diseases its fall is probably real and definite, but if these oth

pulmonary conditions do not follow suit, the conclusion as to the diminution of tuberculosis is almost certainly ill founded. Corrections can accordingly be made by statisticians for such factors as these, and an instance of the necessity for this is afforded by the case of France, to a less extent in her cities than in rural districts. Deficient medical facilities in isolated areas also diminish the degree of accuracy ; the existence of such a fallacy is indicated when the pulmonary cases make up more than 90 per cent. of all cases of tuberculosis—the average figure for countries possessing good medical facilities.

Despite such difficulties it is held that sufficient information is now available to give a good enough foundation for research workers endowed with critical minds and a thorough knowledge of local conditions, medical customs, and successive changes in nomenclature. In city statistics correction must be made for such factors as the attracting to urban hospitals of cases from the countryside ; conversely, the more recent tendency to place sanatoriums in rural areas must also be taken into account. Thus in Sydney (Australia) in 1920 the rate for pulmonary tuberculosis was 51 per 100,000, without including the residents dying outside the city limits, and 61 when these were included. For all forms of tuberculosis the corresponding rates were similarly 63 and 71.

TRENDS OF TUBERCULOSIS IN DIFFERENT COUNTRIES

Tables are given in the report which reveal that the mortality from tuberculosis has diminished in practically all countries for which statistical data are available. In England and Wales and Belgium the fall began in the middle of last century ; in other countries there first appears a rise in the mortality rate, then a peak, and then a downward trend. Such a peak mortality occurred towards 1871 in Scotland, about 1880 in New Zealand, ten years later in Bavaria and Switzerland, between 1896 and 1900 in Ireland and Norway, between 1901 and 1905 in Hungary, in 1905 in Czechoslovakia, and in 1909 in Japan. In most other countries the decline had already started when statistics began to be available.

From about 1750 to 1830 there was in Sweden a slow but steady increase in the mortality from "phthisis," when the average for ten years was 277 per 100,000 ; available figures after that only reappear in 1901, when the rates were slightly under 200, and have since been decreasing. The maximum mortality in that country must therefore have occurred between 1820 and 1830, or between 1830 and the end of the nineteenth century. This phenomenon has been detected in provinces as well as in whole countries ; the period of maximum mortality varying in different provinces, being earliest in the more urbanized, and later in the more rural. The figures available for Stockholm and Sweden permit inferences to be drawn as to what has been happening elsewhere.

There has also been brought to light a remarkable parallelism in the relative fall in different countries and cities during the last quarter of a century. Thus from 1887 to 1929 the rate for England and Wales fell by 58 per cent., and for London also by 58 per cent. From 1896–1900 to 1929 the rate for Austria fell by 56 per cent., and for Vienna by 59 per cent. In other countries the differences have been somewhat larger, but they are still small in comparison with the observed extent of the rate of fall.

SEX DISTRIBUTION OF MORTALITY

In England, Germany, and France the tuberculosis mortality is higher in males ; in Norway, Ireland, Sweden, Holland, and Denmark the male rate is lower than the female. Such relative positions are not constant, however ; in some periods the male rate exceeds the female, in others the position is reversed. Thus in Holland the male rate was higher than the female by 4 per cent. in 1875–79, higher by 5 per cent. in 1901, practically equal in 1905–09, and increasingly lower subsequently, the difference reaching 16 per cent. in 1929. In Belgium the male rate was lower than the female in the middle of last century ; it exceeded it by 12 per cent. in the 'nineties, but the excess has gradually decreased, being practically negligible in 1920, and rising to 7 per cent. in 1928. In England and Wales the male and female rates were equal in 1851–60 ; the male rate then began to exceed the female, the excess growing continuously, and reaching 29 per cent. in 1929. In Prussia, on the other hand, the excess of the male rate, which was 25 per cent. in 1877, gradually declined to 6 per cent. in 1928. In Scotland, as in England, the excess of male mortality increased from the 'eighties to the present time.

Generally speaking, the excess of male mortality is larger in the cities than in the various countries taken as wholes ; it is more pronounced in the great cities, and lower or non-existent in the smaller towns. In rural districts there may even be an excess in the female rate. In Copenhagen, for example, the excess of male mortality amounts to 26 per cent. ; in the smaller towns there is a female excess of 17 per cent., which reaches 31 per cent. in the rural districts. In countries where the population is mostly urbanized the same generally holds good, but not always, and there is no clear-cut correlation between industrial employment and the excess of male mortality ; it is therefore necessary to take into account the factor of age distribution.

AGE DISTRIBUTION OF TUBERCULOSIS MORTALITY

In all countries and periods the highest mortality occurs in the first year of life. The curve then falls rapidly, reaching its lowest point between the ages of 5 and 14, and increasing rather abruptly from 15 to 25. After this it either remains high or decreases according to the type of the community, the country, and the period. The curves exhibit a definite parallelism for both sexes, but show differences, some being constant and others inconstant. During the first year of life there is a regular excess of the male over the female mortality rate, ranging from 20 to 25 per cent., but sometimes reaching as high as 55 per cent. This is attributable to the greater general debility of male infants, a phenomenon worthy of more intensive research than it has yet received. Subsequently, until the age of 12, the rate is the same for both sexes, and remains very low. From puberty until 25 the female rate is higher than the male, in the cities as in the countryside, and in every period of history.

After 25 three types of curve are distinguishable. In Type A the curve reaches its maximum height at the age of 20 to 30, falling then and remaining practically horizontal until about 70, when a second peak becomes observable. Such a flat curve is associated with a low general tuberculosis rate, and is found in Australia, Denmark, Scotland, the United States, Germany, and the Netherlands. The curve for England is closely similar, but rises somewhat higher at the part corresponding to late adult life. Type B has a single mortality peak from 20 to 40, sometimes centred at 25 ; this is followed by a gradual slowing down corresponding with a low mortality in the older age groups. Such a type is often associated with a fairly high general tuberculosis rate of from 125 to 250, and is observed in Japan, Greece, Sweden, and the Irish Free State, and, since the war, in Norway. The curve of Type C, after rising from the age of puberty to 25, continues its upward movement, reaching its maximum in late adult life or even in old age. This curve is found in countries with a comparatively high tuberculosis death rate, such as Switzerland, Esthonia, Latvia, and Czechoslovakia. Cities often show a C curve at one time or another ; Paris has one at present, Oslo showed it in 1871–85, and Amsterdam in 1885–94.

In any country these curves undergo slow changes according to the fall of the death rate evenly or otherwise. In the Netherlands and Norway there has been no recent change, but in Scotland a curve of Type B during the last thirty years of the nineteenth century was gradually transformed into a Type A curve, through a gradual reduction of the toll of tuberculosis on the young adult ages ; the fall at other ages apart from the first year of life being smaller.

The following explanation of the successive changes in the type of curve is put forward. When a generation

is highly infected with tuberculosis in infancy, it presents a persistently high death rate through the normal span of life. A period of high infant tuberculosis mortality is followed after about twenty-five years by a high death rate of young adults, and of mature adults some twenty-five years later again, an interval of some sixty to seventy years elapsing between the waves of high mortality in infants and in old people. A generation of young parents with a high tuberculosis morbidity will in turn give rise to a new generation of infants similarly infected, and so the type of curve will persist, unless new factors supervene to diminish the mortality at one point or another, when the curve will change correspondingly. The influence of these factors can be statistically evaluated by the changes in the curves.

The report ends with a short bibliography, which will be helpful to some statistical inquirers. It is a thought-provoking contribution to the subject of tuberculosis epidemiology, and should serve a useful purpose in checking hasty and speculative conclusions based on ill-digested or even inaccurate statistics.

THE LISTER INSTITUTE

ANNUAL REPORT

In the report of the governing body of the Lister Institute of Preventive Medicine,[1] which was presented at the annual meeting on June 10th, regret is expressed at the resignation, through illness, of Sir James Kingston Fowler, who, until last March, had acted as the chairman of the Board during the absence abroad of Sir David Bruce. Sir James Fowler joined the governing body in 1918; he was a member of the finance committee, and had acted as chairman of the serum department committee. During the year death removed two members of the council—namely, Sir Andrew Balfour and Dr. H. de Riemer Morgan—and also Professor Lorrain Smith and Dr. A. T. MacConkey, both of whom had been members of the Institute since 1907. A brief survey is given in the report of the different lines of research work which have been in progress during the year.

The Viruses of Vaccinia, Variola, and Fowl-pox

Professor J. C. G. Ledingham has continued his study of the Borrel bodies, which occur in very large numbers in the lesions of fowl-pox. It has been shown that the well-known Bollinger inclusion bodies (seen in the epithelial cells of the fowl-pox lesion) consist of agglomerations of these Borrel bodies in a lipoprotein matrix. It is highly probable that they are the actual invading agents, and Professor Ledingham has been able to demonstrate the presence in potent bacteria-free filtrates of fowl-pox of an abundance of these bodies. He has also demonstrated the presence of similar elementary bodies in a new virus isolated from the virus disease of mice. Vaccinia virus has been successfully cultivated by Drs. G. H. Eagles and D. McClean, who have carried it through a considerable series of subcultures; they used an entirely cell-free culture medium, consisting of the supernatant fluid obtained after centrifugalizing a mixture of finely minced fresh rabbit's kidney and Tyrode's solution. The apparent irregularities of virus increase in different flasks during an experiment was encountered in such cell-free media as in others; they are attributed to variations in the reaction to vaccinia virus displayed by individual rabbits. Such variability is now controlled by injecting vaccine lymph into every test animal employed for serum titration purposes. No satisfactory method has been devised yet for preserving virus which has been cultivated in the chick embryo and plasma medium of Carrel and Rivers, but anaerobic storage in the presence of agar gave better results than did other procedures. Attempts by Dr. Eagles to propagate the virus of small-pox in rabbits have been unsuccessful.

Poliomyelitis and Vaccination

Continuing their work which was mentioned in last year's report (see *Journal*, 1930, i, 1187), Drs. R. W. Fairbrother and E. W. Hurst found that when both the small-pox vaccine and poliomyelitis viruses were injected intravenously, the resulting vaccinal reaction had no power to alter the haemato-encephalitic barrier in such a manner as to permit infection of the central nervous system with poliomyelitis. Intradermal vaccination had no influence on poliomyelitis virus which had been inoculated into the brain, and it did not activate or render more virulent a weak strain of the virus. When the two viruses were injected intracerebrally, the two diseases evolved quite independently; if it was arranged that their incubation periods should terminate simultaneously, the characteristic lesions of both existed side by side, without any apparent modification of one by the other. Drs. Fairbrother and Morgan succeeded in obtaining from a horse a greatly improved serum, which it is hoped to employ in the treatment of human poliomyelitis. It was discovered that in this serum the antibody was attached, for the most part, to the euglobulin fraction. Dr. Fairbrother detected antiviral bodies in the serums of normal individuals who had been in contact with cases of poliomyelitis, without, however, developing the disease.

Bacterial Studies

Dr. J. A. Arkwright has been investigating bacterial variation, with particular regard to changes in fermentation reactions and the possibility of there being some correlation between antigenic change and fermentative properties. An assessment of the prophylactic value of variously prepared antiplague vaccines is being made by Dr. H. Schütze. The superiority of the Haffkine prophylactic has been established, while the ordinary agar-grown, heat-killed vaccine has been shown to have no value. In the course of these experiments indications have been obtained that the type of protein supplied to the plague bacillus for its culture has an important bearing on the antigenic efficacy of the resultant vaccine.

Vitamin Studies

Drs. Schütze and Zilva, using rats as the experimental animals, and *S. suipestifer* as the infecting agent, have demonstrated the existence of a very definitely lowered resistance to infection among animals deprived of vitamin A, as compared with those kept on fully adequate diets. Special attention has been devoted to the distribution of vitamin B_1 and B_2 in natural foodstuffs. The theory associating pellagra with a simple deficiency of vitamin B_2 in the diet has been weakened by the discovery that maize and its products are not poorer in this vitamin than are other cereals, and this notwithstanding the fact that the incidence of pellagra is almost wholly confined to populations subsisting on the maize group of cereals. The vitamin B_2 content of maize has been found to be greater than that of rice, and little, if at all, lower than that of wheat. Consumption of rice, however, has only exceptionally been found associated with the incidence of pellagra. Miss Roscoe and Miss D. Graetz found that leaf vegetables, such as watercress, lettuce, spinach, and cabbage, are rich sources of these vitamins, more especially of B_1; while onions, carrots, turnips, and potatoes are much poorer. It was demonstrated, also, that in the cooking of spinach leaves diffusion of the vitamins into the cooking water is rapid, about half the original content being lost in fifteen minutes' boiling.

KING EDWARD'S HOSPITAL FUND

ANNUAL MEETING

The annual meeting of the General Council of King Edward's Hospital Fund for London was held at St. James's Palace on June 9th, with the PRINCE OF WALES in the chair. A message from the King expressed his pleasure at the increased distribution in 1930, and the hope that the public would realize the importance of maintaining the income of the King's Fund and of the hospitals during the present difficult times.

His Royal Highness stated that the distribution in 1930 was £266,000, as compared with £250,000 in the previous year. A gift of £2,000 had been made by the Nizam of Hyderabad, and the British Charities Association had allotted £10,000 for the London hospitals. The year 1931, so far as it had gone, was proving even more difficult than 1930; there was an increase in the number of hospital deficits, but, on the other hand, it should be remembered that the finances of the voluntary hospitals generally before the present crisis had been steadily improving. The difficulties they were now facing, added the Prince, were due to world-wide depression, and not to any weakness in the voluntary system itself. The report of the Hospital Economy Committee showed how the King's Fund had been assisting the hospitals in reducing to a minimum the margin between the number of beds available and the number actually occupied. The report issued on the waking hours of patients illustrated how the Fund collected and circulated data of the present position in this respect in each hospital, and had subsequenty made a definite, though cautious, recommendation. The League of Mercy deserved special thanks for having maintained its grant of £17,000 for four successive years. Moreover, an entirely new and unprecedented item—a special trust fund of £20,000 given by an anonymous donor—had resulted in an income becoming available to assist a hospital to pay off its building debts on condition that no fresh building expenditure was incurred without the approval of the King's Fund. Since the end of the year under review a legacy of £50,000 had been received on behalf of the late Sir Otto Beit; this represented his third recent benefaction to the Fund, which had thus received from this source a total of £106,000.

Accounts for 1930

The total receipts of the King's Fund for 1930 were £493,950. This income was sufficient to cover the increased distribution of £266,000, special grants totalling £16,468 towards the superannuation scheme for nurses and doctors, and the carrying forward of a further £15,000 to reserve for the pensions grants in future years, together with a balance carried forward of £5,600 for the King's Fund. A sum of £116,000 was also added to the capital account as the result of special grants and legacies, including £90,000 under the will of Lord Revelstoke. The number of hospitals receiving grants was 141, as compared with 143 in the previous year. The number of convalescent homes receiving grants rose from 52 in 1929 to 55 in the year under review. Each eligible hospital which had applied for a grant was inspected, and a report was rendered by two visitors on behalf of the Fund, one medical and the other lay. The total sum distributed among hospitals, convalescent homes, and tuberculosis sanatoriums during the last ten years, including all special distributions, was £3,183,592. Since the creation of the Fund in 1897 a total amount of over £6,770,000 has been distributed. In allocating an additional sum of £1,000 to convalescent homes during the year, the Distribution Committee took into special consideration the extent to which the various homes provided medical or nursing treatment or care, thus releasing hospital beds sooner than would have been possible otherwise.

Reports of Subcommittees

The annual list of pay beds published by the Fund shows that the total number of these beds at the end of 1930 was 1,425 at ninety-nine hospitals, as compared with 1,055 at eighty hospitals in March, 1928, when the Pay Beds Committee of the Fund was preparing its report on the whole subject. The insurance scheme for members of the professional and middle classes submitted to the King's Fund by the British Provident Association in 1929 formed the subject of a report published by the Management Committee in 1930. Alternative schemes of premiums have been drawn up making provision for weekly charges for a pay bed in a hospital, or for a bed in a nursing home, and, if desired, for medical or surgical fees also. Contributions were made towards the capital cost of a pay bed, in return for which a subscriber had prior claim to the use of such a bed, when approved for admission according to the rules of the hospital.

Lord Luke, chairman of the Revenue Committee, presented a report on the work of the Propaganda Subcommittee, and commented on the increasing number of ways in which money was being obtained. The committee had also supplied helpful information to the authors of an interesting book, entitled *The Romance of the British Voluntary Hospital Movement*, which was published during the year.

Sir LEONARD COHEN, chairman of the Economy Committee, who reported on the relation between total beds and the number actually occupied in various hospitals, stated that a memorandum on unoccupied beds had been issued in August, 1930. Information was circulated as to the reason given for closing beds, the way in which the occupation of open beds ceased between the times of discharge and admission of patients, and the comparative incidence of vacancies in beds for men, women, and children respectively, in medical and surgical wards.

DIET AND DISEASE IN NATIVE RACES IN THE TROPICS

During the past ten years the conception that disease may be due to deficiency of this or that element or complex in the food has developed greatly. Formerly, the idea of "deficiency disease" centred round the vitamins, and in this category only such conditions as scurvy, beri-beri, rickets, and keratomalacia were included. Now, however, it is gradually being realized that vitamins are not the only substances the absence or insufficient supply of which may give rise to deficiency disease; and that lack of a sufficiency of such mineral elements as calcium, iron, iodine, manganese, and possibly some of the rarer elements, may also cause disease of this order. The truth is slowly being made plain that man is composed of what he eats; that defects in the architecture of the human edifice are largely due to defects in the quality of the food, especially during the growing period of life. These defects are often at the root of disease processes which manifest themselves clinically in later life, and they can be prevented, or, when established, they can (if not too far advanced or complicated by superimposed infection) be rectified, by correcting defects in the composition and balance of the dietary. It is slowly being realized also that not only is the bony framework of the body affected adversely by faulty food, but the tissues generally; that the functional efficiency of all cells, the maintenance and harmonious regulation of chemical processes in the tissues, the composition of the blood and body fluids, and the capacity of the organism to resist many infectious agencies, are all dependent, in great measure, on the quality of the food and on the balance between various constituents of it. Accordingly, the idea of "deficiency disease" has now a wider significance, and soon it will have served its purpose and given place to another—namely, that of disease associated with faulty nutrition of any kind in which maladies affecting every system of the body—respiratory, digestive, urinary, endocrine, and nervous—will have a place.

This knowledge has, for the most part, been gained by experiments on the lower animals, and the time is now ripe for controlled investigations "in the field" which will correct, supplement, and confirm those of the laboratory. Such an investigation is that recorded in the report by Drs. J. B. Orr and J. L. Gilks, recently issued by the Medical Research Council.[1] The report deals with the physique and health of two African tribes, living side by side under similar climatic and hygienic conditions. The diet of the one (the *Akikuya*) consisted mainly of cereals, being very rich in carbohydrates and deficient in animal protein, fats, calcium, and vitamins A and D—defects commonly conjoined in certain native dietaries in India. That of the other (the *Masai*) consisted mainly of meat, milk, and raw blood—a diet too rich in protein and too poor in carbohydrates and fresh vegetable foods. The members of the former tribe were, in general, of poor physique, and abnormalities of bone, dental defects, spongy gums, anaemia, yaws, malaria, bronchitis, pneumonia, phthisis, rheumatism, helminthiasis, and tropical ulcer were of common occurrence among them. Those of the latter tribe were of much better physique and were significantly less affected by most of the ailments mentioned; but they suffered more from constipation and arthritis than did the former tribe. Further, the dietary of the young children, the girls and women of the Akikuya, was better balanced than that of the older boys and men, and this appeared to be "clearly reflected in differences in physique and health." Generally speaking, physique and health were better in the young children, girls, and women of this tribe than in the older boys and men. This experience points in the same direction as a recently recorded observation in albino rats (*British Medical Journal*, June 6th); and it is difficult to resist the conclusion that there was a definite relation between the diet and disease-incidence of the two human communities.

In addition to their clinical observations the authors of the report have brought forward experimental data which "lend support to the suggestion that deficiencies in the diet, abnormal composition of the blood, and reduced susceptibility to certain diseases which have been noted in the Akikuya tribe, may be correlated." Of particular interest in these respects are their findings relating to calcium deficiency. Tropical ulcer was found to be associated with high phosphorus and low calcium content of the blood in ulcer cases.

The importance of investigations of this kind at the present stage of evolution of knowledge concerning nutrition can scarcely be overestimated. They have "a great interest in relation both to general scientific questions of nutrition and to particular problems presented by the native races inhabiting British colonies in the Tropics"; and "the information obtained from them is calculated to hasten the improvement of the physical condition of the native and to increase his importance as an economic factor." The close relationship between diet and the physical efficiency and health of the people of India and its economic importance to that country have been emphasized from time to time during the last few years in India; and evidence to that effect has been given before two Royal Commissions in India—that on agriculture (1926) and that on labour (1929). Experience in India is in general agreement with the conclusions arrived at by the authors of this valuable report.

The report is one which has not only a great interest for medical men and administrators in the Tropics, but the findings therein have an interest also for those nearer home.

Scotland

HEALTH OF SCOTLAND

The following notes, extracted from the second annual report of the Department of Health for Scotland,[1] are in continuation of the paragraphs published in this column on June 13th (p. 1041).

Housing and Town Planning

The Housing (Scotland) Act, 1930, is the ninth Act passed since the war to deal with housing in Scotland. In the eleven years up to December 31st, 1930, during which State assistance has been given, 117,353 subsidized houses have been built, while 12,797 working-class houses have been provided without subsidy; these 130,150 houses practically represent the shortage estimated by local authorities in 1919. About 100,000 houses of the working-class type, however, are still required. The report points out that with the stabilization of subsidies, the local authorities have now extended their programmes, and that plans have been approved by the Department for the erection of a much larger number of houses than in the preceding year. Some thirty-nine local authorities, including three county authorities, proceeded during the year with slum clearance schemes, under which 17,712 occupied houses were condemned. The problem of providing urgently needed houses in rural districts is complicated by the fact that the population in these areas is dwindling, while the cost of building is higher and the rents are lower than elsewhere. Town planning in Scotland made little progress during 1930, but about eight town councils resolved to prepare schemes for portions of their areas still undeveloped.

Infectious Diseases

The chief infectious disease during 1930 was scarlet fever, 16,393 cases being notified. This figure, however, is lower by about 1,000 than the average incidence of the last decennium. Notifications of diphtheria (11,580) exceeded those of the previous year (10,471), but a notable decrease of 4,500 cases is recorded in the figures for pneumonia. Pulmonary tuberculosis occurred in 5,689 cases during the year, compared with 6,112 in 1929, while the corresponding figures for non-pulmonary tuberculosis were 4,286 and 4,228 respectively. It is satisfactory to note that the mortality from tuberculosis in Scotland continues to decline, the death rate of 88 per 100,000 of population for 1930 comparing very favourably with the previous lowest recorded rate of 94 in 1929. With regard to venereal diseases, the number of patients treated up to May, 1930, was 30,281; of the 17,687 new patients, 12,054 (72 per cent.) were found to be infected. Patients discharged after tests as cured numbered 4,525.

Highlands and Islands Medical Services

Following the passing of the Highlands and Islands (Medical Service) Additional Grant Act, 1929, a sum of £30,000 was voted for this service in addition to the annual grant of £42,000, and a further sum of £10,000 in respect of mileage and other special charges for medical benefit was transferred from the Scottish National Health Insurance Fund. The number of practices in which services are rendered under this scheme is 154. Grants-in-aid have been given as in previous years for surgical services in hospitals at Lerwick, Kirkwall, and Stornoway. The report points out that the recent extensions carried out at the Royal Northern Infirmary, Inverness, will enable a much better service to be provided in the Highlands, and for this purpose a grant of £5,000 per annum is being given to this hospital for ten years,
